Although these recommendations were accepted in principle by the Ministry of Education, there are few signs that the implementation of the report of the Percy Committee is being regarded as a matter of urgency. This is clearly indicated in Circular 133 of the Ministry of Education. In directing local education authorities to prepare and submit their development plans for further education not later than March 31, 1948, the Minister reminds them that they must have regard to facilities for further education provided in their areas by universities, educational associations and other bodies, and to consult such bodies and local education authorities for adjacent areas. It is assumed, adds the Minister, that local education authorities will work in close touch with the regional councils for further education; but, because such councils have *not* been universally established throughout the country, he has been compelled to add that he will require assurance from some authorities that they have complied with the requirements of the Education Act regarding consultations.

It is therefore not surprising that the Ministry has issued a provocative and suggestive pamphlet* "designed to survey the whole field of further education as an entity, in order both to indicate the part which each feature of it should play in relation to the whole and to suggest possible lines of future development". Still less is it surprising, on account of the tardiness of local education authorities in establishing regional committees, that the emphasis should be upon regional co-operation. Much of it is, indeed, written in elucidation and explanation of the views expressed in Circular 87. On grounds of economy it would be improper, particularly in the higher range of studies, for each local education authority to attempt to provide for all the needs of students living in its area. Nevertheless, economy is not the only factor in regional organisation. There are many positive functions which a regional body can usefully perform; these include the planning of new developments, the expansion of existing facilities, the review of courses and curricula, the most effective use of specialist staff. "To a special degree, our fortunes to-morrow depend upon the extent to which our plans for technical and commercial education are placed to-day in the forefront of our reconstruction programme, and the vigour and vision with which they are carried through."

The deeper significance of the pamphlet lies in the interpretation of this generalization—the conception of further education as an entity. There is the realization that the planning of technical and commercial education is only a part, however important, of a larger task. The immediate responsibility of local education authorities is to assume leadership in the co-operative enterprise of community education; and such education is defined as embracing both skill and social leadership. In addition to possessing the technical knowledge required to meet the highly specialized demands of industry and commerce in a scientific age, men and women must, it is postulated, have an understanding of everyday human relationships. "Industry to-day is a large-scale social organisation and success in it will depend upon qualities of personality no less than upon acquired knowledge." To a very much greater extent than in the past it has, therefore, become necessary to foster corporate life and to extend the range of students' interests and social powers.

Whether, or to what extent, local education authorities will be able to unify work in the field of further education must remain speculative. It should, however, be noted that the Education Sub-Committee of Nuffield College† recently expressed the view that, without seeking to minimize the truly educational work done in technical colleges, philosophy, history, literature and pure science should be recognized as having their own sphere. "'Organised cultural training' is," the statement continues, "in the Education Act put with 'recreative activities' as coming under leisure-time occupation. A further link between these is forged by the Government pamphlet on Community Centres." It is, however, significant that the Ministry has not only organised one department to deal with technical education and "organised cultural training and recreational facilities", but has also indicated to local education authorities that "since, in many areas, the requirements for compulsory part-time education will be within the premises of a single college planned to meet local needs of further education—both compulsory and voluntary—it is essential to regard the requirements of Sections 42 and 43 as part of an integrated whole".

What would, consequently, seem to be indisputable is that local education authorities must, in preparing their plans for further education, give as much consideration to the potentialities of the individual man and woman as to the types of studies and activities to be provided. There are at least two lessons to be learnt from war-time experiences in H.M. Forces. First, the number of people who are ready to take advantage of formal educational activities (other than those which are purely vocational) is relatively small. As Sir Richard Livingstone has said, in paying tribute to the work of the Workers' Educational Association, "it is remarkable until you remember that there are forty-three million people in this island". Secondly, there is reason for believing that a high percentage of the majority who are repulsed by formal education are attracted to informal activities and responsibilities which are shared appropriately among all concerned; and it is of the greatest importance that these men and women should not seek in vain for opportunities to pursue similar interests in civilian life. If the individual is to be socially adequate in a constantly changing world, he requires adaptability and flexibility towards personal and social no less than towards economic and vocational problems.

For this, if for no other reason, it is perhaps fortunate that the difficulties to be overcome are not wholly organisational. Much will obviously depend on the concept of education possessed by those who specialize in work among young people and adults. There are, happily, increasing indications that the compartmental concept of education is being replaced by the integral. In an earlier age educational practice was undoubtedly over-compartmental and, in consequence, society-blind. It either could not see, o failed to admit, the existence of society and the relationship of the individual to it as a relevant factor in human affairs. That it is being replaced by the integral concept is, in large measure, due to the pioneer work which has been done in adult education, the acceptance of the principle that education is a life-long process and the realization that society is, or can become, an educational agent. "The lif of Man is," as A. N. Whitehead has written, "founde on technology, science, art and religion;" and it is the ideal of the good educationist to look to the whole man—the good man, the good citizen, and the usefu man.

* Further Education. (H.M. Stationery Office.) 2s. net.

† The Further Education of Men and Women: a Task of the 1944 Education Act. (London: Oxford University Press.) 1s. net.

How necessary the acceptance of this ideal has become may be illustrated simply. The achievements of modern technology have been part of a culture of which the central theme has been the seizure and exploitation of power and the increased use of non-human sources of energy. What concentration on the development of this culture has, however, tended to obscure is that, the more energy man commands, the more important it is that this energy should be at the service of his whole personality, and not merely at the command of some narrow ambition or some limited goal. So far as science and technology have been wedded to narrow concepts of human development and human well-being, they have given power to military, political, and financial despots, they have fed their egos and justified their ambitions, they have further brutalized the brutal and corrupted the corrupt. They have, in a variety of ways, disintegrated the life of man by making him the victim of the machine rather than its commander and controller.

Men do not live by machines alone, and the power impulse, however deep and ineradicable, is neither self-sustaining nor self-sufficient. Machines are not—and never can be—a substitute for vital human needs, many of which are frustrated by over-emphasis on the quantitative and mechanical. The hiatus which now exists between those parts of life which have become controlled by machines, and those parts which lie outside their scope, constitutes one of the gravest problems of contemporary society. Nothing less than the autonomy of the human personality is at stake, and it cannot be saved unless the social context in which man has to act and to survive is given adequate attention.

FOSSIL MAN

Les hommes fossiles

Éléments de paléontologie humaine. Par Prof. Marcellin Boule. Troisième édition par Henri V. Vallois. Pp. xii + 587. (Paris: Masson et Cie., 1946.) 1200 francs.

SINCE it first appeared a quarter of a century ago, Boule's treatise on fossil man has become one of the recognized classics of human palæontology. It has been particularly noted for the clarity of its exposition and for its very fair summarization of the sort of evidence (often sparse and difficult to interpret) upon which palæontologists have to rely. It was primarily also a personal exposition, reflecting the results of the author's original observations and his own assessment of the evidence presented by others. Between 1934 and 1939, Boule worked on the revision of his book for a third edition, and during this time had completed the first eight chapters (that is, more than half the volume). It had been his intention to complete the revision on his retirement; but the outbreak of war and his death soon afterwards prevented this. However, the task has been undertaken by his colleague, Prof. Vallois, than whom no better qualified editor could probably be found.

No doubt the main difficulty of the editor must have been to give adequate expression to the wealth of new discoveries bearing on prehistoric man which have been made during the last few years. But Prof. Vallois has taken the wise course of retaining the individuality of Boule's classic book even at the risk of leaving it somewhat unbalanced as a representative account all the additional evidence relating to the evolution of *Homo sapiens* which has quite lately become available. On the other hand, all the most recent evidence is included by reference, even though in some cases it may not be treated in the detail which its importance might seem to require.

Boule's was clearly a 'master mind' in the sense that he had an intimate knowledge of details and at the same time a really comprehensive grasp of the subject of human palæontology as a whole, and it is worth while considering his main conclusions concerning some of the more obscure problems which still provoke controversy.

As regards 'tertiary man', in so far as the solution of this problem depends on eoliths the author expresses himself with extreme caution. He definitely rejects the evidence which was presented so forcibly by Ray Lankester and Reid Moir, and in regard to other evidence he concludes that we have no infallible means of distinguishing the fortuitous natural chipping of 'eoliths' from the products of an intentional handiwork which in any event was extremely crude. The osteological evidence provided by all the *Pithecanthropus* material now available from Java, and also the remains of Pekin man, is considered at length, with the general conclusion that they should be grouped together as "Préhominiens", indicating their ancestral relationship to Neanderthal and modern types of man. The author emphasizes very strongly the close relationship of the Javanese and Pekin fossils, and insists that the differences between them have at most a specific (and certainly not a generic) value. This conclusion is in full accord with the view now commonly adopted by palæontologists that the original nomenclature of Davidson Black, *Sinanthropus pekinensis*, should be replaced by *Pithecanthropus pekinensis*.

The discussion of Neanderthal man occupies a relatively large portion of the book, as might be expected from a consideration of Boule's classical study of the almost complete skeleton found at La Chapelle aux Saints in 1908. The view is taken that *Homo Neanderthalensis* was essentially a specialized and somewhat aberrant form which became extinct and played no part in the evolutionary development of *Homo sapiens*. This interpretation also now receives wide accord, and, indeed, it could scarcely be otherwise since the accumulation of evidence provided by the Ehringsdorf, Steinheim and Swanscombe skulls, to say nothing of other evidence (including that from East Africa) which indicates the existence of *Homo sapiens* in pre-Mousterian times. The negroid affinities of the Aurignacian skeletons from Grimaldi are accepted; but the strong arguments which have been adduced for the Eskimoid nature of the Magdalenian skeleton of Chancelade are vigorously contested. Lastly, Cro-Magnon Man is believed to survive still in parts of the Dordogne and in the population of the Canary Islands.

A phase of human palæontology which receives inadequate treatment is that represented by the now famous Australopithecine fossils of South Africa. These important discoveries are quite cursorily dealt with in scarcely more than three pages and, although it is conceded that they are the most human of fossil apes which have so far been discovered, they are given no particular place in the theme of human evolution. Had Boule lived long enough to learn the mass of evidence regarding these remarkable fossils which has accumulated during the last few years, and particularly if he had been able to read the monographic study on the Australopithecinæ recently published by Dr. Robert Broom, there is little doubt that he would have recognized their importance by devoting much more space to their consideration.

An interesting feature of this new edition is the fact that more than 130 pages are now occupied with discussions of the remains of fossil man and his cultures which have been discovered in other parts of the world besides Europe—India, Malaya, Oceania, Australia, Africa, North America and South America. This is interesting as an indication of the increasing attention which is being directed to archæological research outside Europe. It may be surmised that in a future edition the geographical balance will be altered still further, for it is becoming more and more clear (particularly as the result of recent discoveries in the African continent) that the early palæolithic populations in Europe may have been little more than the 'stragglers' of much larger and more highly organised communities which were responsible for developing the characteristic palæolithic cultures in parts of the world less disturbed by gross climatic fluctuations. It is perhaps scarcely necessary to add, of a book so well known in its previous edition, that the illustrations are both excellent and numerous. W. E. Le Gros Clark

BIOLOGY OF CARCINOGENESIS BY CHEMICAL COMPOUNDS

Les cancers produits par des substances chimiques exogènes

Par Prof. Antoine Lacassagne. (Radiophysiologie expérimentale cancer et hormones, 5 : Actualités scientifiques et industrielles, 1003.) Pp. 166. (Paris : Masson et Cie., 1946.) 150 francs.

THIS monograph by Prof. Lacassagne is one of a group which will cover the subject of carcinogenesis and deals with the production of cancer by chemical substances. In the first chapter the author discusses arsenical cancer. Arsenites were indicted as carcinogenic agents so long ago as 1820, but no unequivocal evidence has ever been produced to show that arsenic is carcinogenic. No reference is made to Prof. E. L. Kennaway's discussion of this part of the subject under the title of "A Contribution to the Mythology of Cancer Research" (*Lancet*, 2, 769; 1942); but this paper may not have been available in Paris when the monograph was written. Although arsenites have not been shown to be carcinogenic in experiments on animals, they are mitotic inhibitors belonging to the class of radiomimetic poisons which also includes some of the vesicants. The relation between mitotic poisons and carcinogens is still obscure, but urethane is a carcinogen which inhibits mitosis.

The second group of substances considered are the nitrogen-containing polycyclic compounds which have been of interest since 1906, when it was shown that cancer of the bladder occurred abnormally frequently in workers handling fuchsine and naphthylamine. Cancer of the bladder has been induced experimentally in animals by three substances: β-naphthylamine, *o*-aminoazotoluene and 2-acetylaminofluorene. Some aromatic nitrogen compounds such as 2 : 2′-azonaphthalene, 2 : 2′-diamino-1 : 1′-dinaphthyl and 4-dimethylaminoazobenzene are able to induce cancer of the liver. The action of this type of compound on the liver is dependent upon the diet on which the experimental animals are maintained, the incidence of cancer of the liver being much higher in animals maintained on 'poor' or low protein diets. This may be connected with the high incidence of cancer of the liver in communities such as the Bantus and Japanese, where low protein dietaries are common. The author points out how the compound Styryl 430 is unique in being a water-soluble aromatic carcinogenic compound. Finally, the nitrogenous carcinogens include substances resembling the carcinogenic hydrocarbons in which a carbon atom is replaced by nitrogen as in the benzacridines and dibenzcarbazoles. One of these, 3 : 4 : 5 : 6-dibenzcarbazole, forms a link in that it is capable of producing tumours at the site of application as the hydrocarbons do, and also producing cancer of the liver like many aromatic amines.

The last hundred pages of the book are devoted to the carcinogenic hydrocarbons from the point of view of a biologist rather than from that of a chemist, as the chemistry of carcinogenesis will be discussed in a separate volume by Prof. N. P. Buu-Hoï. The general rules relating carcinogenic activity and chemical structure are indicated, but the emphasis is on the history of the subject and the biological experiments. Advances in our knowledge of biological actions are often dependent on methods of testing. Methods for testing carcinogenic activity were first developed in Japan, but used to great effect by European workers, particularly by research workers at the Royal Cancer Hospital, London. A carcinogenic substance was isolated from coal tar, and a large number of synthetic hydrocarbons shown to be able to produce cancer on the skin of mice. Coal tar is usually too toxic to be used for injection into the body, but the preparation of pure carcinogenic hydrocarbons made it possible to produce cancer of many organs in different species of animals. Prof. Lacassagne refers to injection as "la méthode américaine", in contrast to painting the skin with the carcinogenic substance or "la méthode anglaise".

Experiments carried out in many laboratories have shown that tissues and species of animals differ widely in their susceptibility to carcinogenic substances. The epidermal and connective tissues are the most sensitive, and the alimentary tract is relatively resistant. Tumours have been induced by carcinogenic hydrocarbons in mammary glands, testes, kidney, liver, prostate, brain, lung, salivary glands and connective tissue. A separate chapter is devoted to the induction of tumours of the alimentary tract and of the lung. These two sites are of great importance from the point of view of human cancer, but attempts to produce tumours of the stomach or lung in animals by hydrocarbons have given most erratic results. The tumours of the stomach which have been induced in mice are not comparable with gastric cancer in man. This is a part of the subject which requires much more investigation before the carcinogenic process is understood. The application of carcinogens to the blood-forming organs either directly or by injection of circulating carcinogenic substances leads to leucæmic changes which may be malignant and vary enormously in type.

The whole review, written by a leading worker in the field, forms an interesting discussion of the effects in different species and in animals of different genetic constitution, of carcinogenic substances in various media administered by divers routes. E. Boyland

Racial Pride and Prejudice

By Eric John Dingwall. Pp. x + 246. (London: Watts and Co., Ltd., 1946.) 8*s.* 6*d.* net.

THIS book deals with an important world problem from the point of view of the anthropologist and the psychologist. It is intended for the general reader rather than the student of either of these sciences, and Dr. Dingwall is to be congratulated on the way he has managed to avoid technical language except where it is absolutely necessary. The book has another great advantage in that the author is not only content to present the facts as he sees them, but also does not hesitate to insert short discussions of the possible reasons that lie behind customs and legislation associated with the colour bar. The combined presentation makes admirable reading. It is unnecessary in a notice of this character to stress the sane, but nevertheless realistic, point of view of the author; it would be more appropriate to direct attention to other special merits that the book possesses. One of these is the admirable psychological approach to the problem of prejudices in general and colour prejudice in particular, and Chapter 14 on the psychology of racial and colour prejudice is a masterful essay in itself. The reader is impressed particularly by the part that jealousy plays in this respect.

To the geography student the book has yet another distinct advantage in so far that the treatment is global. There are chapters on the colour bar in the United States of America, Great Britain, Africa, the West Indies, India and the East, Brazil, Australia and New Zealand, and the U.S.S.R. Such a complete world survey is admirable and will be much appreciated by the student of human geography. The author states in his preface that references and footnotes have been cut down so far as is possible in a book of this kind, and that if authority were to be quoted for every statement the bulk of the book would be almost double and its value would not have been increased in proportion. Nevertheless, the addition of a few well-selected maps showing, for example, the distribution of the Negro population in the United States, or the white population in the Union of South Africa, would be most welcome. The general reader, for whom this volume was written, is ignorant of these essential facts, and while the addition of a few distribution maps would not have made the volume more bulky, it would have increased its value very considerably.

E. G. BOWEN

Introductory College Chemistry

By Prof. Harry N. Holmes. Fourth edition. Pp. x + 590. (New York: The Macmillan Company; London: Macmillan and Co., Ltd., 1946.) 18*s.* net.

THIS very attractive book is now in a fourth edition and has been considerably revised. Although its title, and the statement in the preface that it "is of full college grade", suggest a moderately advanced book, it is really of a standard that would be used in schools in England, and in many parts does not reach Higher School Certificate level. The charts and illustrations are often suitable only for very immature students.

The sections on the metals are dispersed, group methods of preparation and group reactions being stressed. The physical chemistry is presented in some detail, and there are whole chapters on the structure of the atom and nuclear chemistry. Chapters on organic chemistry include matters of technical interest or of importance in daily life, such as hydrocarbons, rubber, carbohydrates, plastics, and food and nutrition. There are references to literature (including some English journals) and questions. In many cases the information is very slight: the only property of carbon disulphide (which has five lines of text) mentioned being that "one pound is needed in the manufacture of three pounds of viscose rayon". The sections on selenium and tellurium, on the other hand, extend over nearly two pages. The validity of the formulæ of orthonitric acid on p. 303, with 5-valent nitrogen, is doubtful. Mercurous compounds are formulated with univalent mercury. These are minor points; generally the text is very clear and accurate.

What will interest most readers is the very large number of out-of-the-way and striking facts which are worked into the text; teachers should find many of these likely to stimulate interest. Although the book is not suitable for English school courses, and is much too elementary for junior university use, it is one which can be recommended as likely to be popular in a school library and useful to the teacher. The production is excellent and the price, although rather high for its size, is not prohibitive.

The Scottish Railway Network

A Project for Reconstructing the Scottish Railways according to certain New Railway Network Principles. By J. F. Pownall. Pp. 72. (Birmingham: Cotterell and Co., 1946.) 8*s.* 6*d.*

IN this small volume Mr. Pownall returns to an exposition of his hour section principle which he outlined in his "New Railway Network Principles". The present volume deals with Scottish railways. The central idea is that full value cannot be derived from most railway lines because, in spite of good speeds, continuity of movement is hampered. The author would ensure fast journeys on the trunk lines, and the more important branch lines, by recognizing certain "hour stations" on all important routes. Some of these would be stations of present importance to-day, others of little importance and others new stations. Expresses would call at these stations and these only, at precise hour intervals, and connect with slower intermediate trains. Several new lines would be necessary. The scheme is ingenious and deserves consideration in any plans for the modernization of the railways of Great Britain.

The Faroes in Pictures

By Gordon Huson. Pp. 82. (London: George Allen and Unwin, Ltd., 1946.) 10*s.* net.

THE Faroes are little more than a group of huge volcanic rocks reaching to heights of several thousand feet above sea-level. They lie on the Faroe-Icelandic ridge 200 miles from the nearest land, which is Scotland. Rainy, windswept and infertile though the islands are, their growing population numbers nearly thirty thousand and is fairly homogeneous of early Norse descent. Only three per cent of the land area is cultivated, and most of that is used for sheep grazing. The main occupations are fishing and whaling. The comparatively small caaing or grind whale is caught in numbers. Little in English has been written on these Danish islands. The exigencies of war led to a British garrison, and Major Huson, who was in that garrison, has produced a charming and useful book of pictures to which is attached a very brief account of the islands. The pictures give an excellent idea of the land forms and the surface conditions.

THE LATE-GLACIAL PERIOD

By P. TALLANTIRE and S. M. WALTERS

Botany School, Cambridge

A DISCUSSION on "The Survival and Extinction of Flora and Fauna in Glacial and Post-glacial Times: the Problem Viewed in Relation to Quaternary Historical Investigations" was held by the British Ecological Society at a meeting in the rooms of the Royal Society on October 15, 1946. The president of the Society, Dr. A. S. Watt, pointed out that it was eleven and a half years since the same rooms had witnessed the Royal Society discussion on the "Origin and Relationships of the British Flora". Although there were a number of contributions from pollen analysts in the original discussion, the emphasis had now shifted towards the lines of evidence that they could supply. This meeting was one of a number then being held in connexion with a conference for Quaternary history in north-western Europe.

The first speaker, Prof. K. Jessen, of Copenhagen, said that in previous discussions, as for example at the Royal Society in 1935, all shades of opinion had been represented, from 100 per cent extinction of the British flora and fauna at maximum glaciation, with subsequent immigration, to 100 per cent survival. The real need was for reliable evidence based on actual, macroscopic remains of the plants and animals in question, particularly thermophiles, in glacial and late-glacial deposits. These evidences are few at present, and somewhat idle speculation correspondingly excessive. He gave a résumé, with slide illustrations, of the probable course of the late-glacial vegetational development in north-west Europe, and possible climatic inferences. Commencing with his three late-glacial periods: I. Older *Salix*; II. Allerød; III. Younger *Salix* time: distinguishable in Denmark, north-west Germany, and Ireland, he tentatively equated the Younger *Salix* period with the formation of the Salpausselka moraine stage of the Scandinavian ice-retreat. Subsequent developments were considered to be post-glacial.

A distribution map for period II showed 'tundra' in North Denmark, 'park tundra' to the south, and the northern border of pine and birch forests in South Baltic regions. In Ireland there was 'tundra' over most areas, possibly *Empetrum* heath in the north and north-west. The forest northern border definitely lay well south of Ireland, but so far its position was unknown for England and Wales. He stressed the difficulties of characterizing the vegetation zones by names, since the conceptions, for example, 'tundra', varied considerably in different regions. 'Park tundra' was intended to connote a tundra vegetation with patches of bare moraine, patches of dwarf salices, *Betula nana*, *Dryas octopetala*, etc., and occasional copses of larger birch species in favourable localities. In Zone III certainly no woods were suggested, as evidenced both by the absence of macroscopic remains of tree-birch, there being only one certain locality for this type of birch in Ireland in the Younger *Salix* period.

Late-glacial sea-levels were known to have been as much as two hundred metres lower than present ones, so that former land-connexions, for example, England to Ireland, Ireland to Spain, and the former southward extension of land in the Solent region in England, may have existed and may possibly have borne forests, for example, of *Arbutus*, in an oceanic wood flora to the west of Cornwall, as has been suggested (by Du Rietz).

The difference between vegetational development in Ireland and in Denmark was considered due, then as now, to more oceanic climatic influences in the west. The pattern of post-glacial development is parallel in the two countries. In the first post-glacial zone, Zone IV of Jessen, birch (*Betula pubescens*, agg.) enters in large amount and has an over-all dominance; pine is very insignificant both in the pollen curves and macroscopically. Large willow species are frequent. At the same time, there is an immigration of thermophile aquatic species in both countries, for example, *Ceratophyllum demersum*. In Zone V, with birch dominance and a spread of hazel, there occurs the first certain evidence for pine, although still in small amounts. In Zone VI*a*, with an astounding hazel preponderance, the two species of *Naias* appear in Ireland, having been present in Denmark in Zone V as well; *Naias marina* represented in a few localities, *N. flexilis* in slightly more. The hazel maximum phenomenon, with traces of mixed oak forest (*Quercus* + *Tilia* + *Ulmus*), is observable all over north-western Europe. Its meaning or contemporaneity are both so far unknown. Uncertain, too, is the pine maximum, in the Boreal Zone VI*b* in the west of Ireland but delayed until VI*c* in the north-east.

Since *Naias flexilis* occurs in Ireland at the present day, its presence in Zone VI may indicate that it is a survival species, at least, that is, indigenous and not re-introduced by human agency. A similar point was made for *Eriocaulon septangulare*, the pollen of which is found in Zone VII*a* at Roundstone, a present-day west Ireland locality as well. Three *Erica* species occur in the Roundstone deposits—the Atlantic species *E. cinerea* from Zones V and VI, *E. tetralix* from Zones V–VII*a*, and one of the Lusitanian species, *Erica Mackaii*, macroscopically identified from leaves, from Zones VI and VII*a* and from inter-glacial deposits in the west of Ireland. The present distribution of *E. Mackaii* is Portugal, north Spain, and a few localities in western Ireland apparently as in Boreal times. It is absent from France.

Dr. Jessen concluded by saying that survival and subsequent immigration of species in Denmark was believed to have centred on south-east and south-west Europe. The speed of immigration had been no quicker in Ireland, thus it seemed unlikely that the Irish species survived so close to Ireland as the debatable southern land surface towards the Bay of Biscay.

Dr. J. Iversen, of the Danish Geological Survey, spoke next on some steppe elements in the Danish late-glacial flora and fauna. The first indications of such an element were encountered in the 1800's when Steenstrup described the ground squirrel (*Spermophilus rufescens*) in a late-glacial freshwater deposit. More recently plant evidence has come to light, and other faunal remains can be roughly dated by pollen analysis methods. Late-glacial finds, in the so-called reindeer period, comprise surprisingly few 'arctic' forms, including only a skull of a mouse hare (*Lepus timidus*) and a jaw of the glutton. Even these, together with the reindeer, are not solely restricted to an arctic–alpine range but may penetrate the forest belt. Steppe forms have an equal frequency. Time and distribution maps were shown for the bison and wild horse from late-glacia and preboreal periods, one find each of the ground-squirrel and mouse have been made from the late-glacial, and four finds of the Irish giant deer dating from the late-glacial and early Allerød. The latter may represent a third, woodland, element restricted to the milder Allerød and post-glacial periods in Denmark. Similarly in north-west Germany, at Ahrendsburg and Meiendorf, bones of the wild horse are reported from the late-glacial stages of the deposits. The plant indices are the high frequencies of *Artemisia* and *Hippophæ* pollen from late-glacial maxima of non-tree-pollen. Presence of *Hippophæ* is proved by finds of the peltate scales. Another index, a species of *Helianthemum,* now found in Central European mountains, but not in Scandinavian mountain regions, is frequent among late-glacial pollen samples. If on retreat of the ice from Denmark the tundra belt disappeared and forests extended practically to the ice margins, then suitable habitats for steppe elements would disappear and no subsequent immigration prove possible, since "the forest is inimical to both arctic and steppe elements". The mixed 'tundra' and 'steppe' flora and fauna probably existed in the belt of 'park tundra', rich in grasses and herbs, of up to a hundred kilometres wide as envisaged by Jessen. This zone and the associated fauna disappeared when post-glacial forest invasion commenced, only the bison and the wild horse lingering until the Maglemosean era in Denmark.

Prof. K. Faegri, of Bergen Museum, dealt with the position of *Hippophæ rhamnoides* in Norway, which in north Europe is restricted to the shores of the Baltic, the north Norwegian and south Danish coasts. Elsewhere in the 'regio alpina media' in Asia, and to sea-level in Scandinavia, it shows a fair degree of tolerance though with some preference for calcareous soil. The fossil distribution appears to have been wide in late-glacial times. A scarcity of localities from Norway is probably due to a scarcity of investigations. Knowledge of ecology suggests that its disappearance is unlikely to have been due to temperature changes. Competition, or the lack of it, or soil leaching are more likely factors, as is indicated by present distribution on regions of coastal uplift, that is, where new ground is continually present and where *Hippophæ* acts as a pioneer species and so maintains itself. The one or two inland stations recorded are similarly on friable calcareous cliffs where rockfalls keep the habitat open. It may be that until the post-glacial forests closed in there existed habitats of suitable open ground or with minimal competition in the shrub layer.

Dr. F. Mitchell, of Dublin, described discoveries in Ireland of remains of the giant Irish deer and reindeer. Recent work in Ireland on 'zoned' plant beds in relation to glacial deposits has led to a modification of Charlesworth's views of the distribution of the Newer Drift as shown in his map of 1929. This is the separation of the mountain glaciation phase in Ireland, principally of the Wicklow Mountains (and perhaps correspondingly, therefore, in the Welsh Mountains), as of a later date than the Newer Drift. The Scottish Re-advance may well date from this phase as well. In the lowlands solifluxion deposits were formed during the period of Jessen's Zone III. Two distribution maps were shown, one for late-glacial deposits, and localities with finds of giant Irish deer actually found embedded in such deposits, the other constructed for finds recorded in the literature, whether supported by reliable field evidence or not, of reindeer finds from open country sites (finds from limestone caves being neglected). There is a frequent association of reindeer bones with those of the giant deer, for example, at Ballybetagh.

In localities surrounded by steeper and better drained slopes the solifluxion layer may contain such arctic plants as *Armeria* (?*arctica*), *Dryas octopetala* and *Oxyria digyna.* The distribution of the two large mammals tends to be general except for a lack in the north and north-west. This compares with Jessen's recognition of tundra or open willow and juniper woods over most of Ireland, and *Empetrum* heaths in the north-west in the Allerød period; the former areas being grassier and thus possibly preferred by reindeer. The Allerød period appears to have been the period when the giant deer flourished; later finds of it are of dubious validity. One from the region to the north of the conjectural ice limit of the Scottish re-advance stage in Ulster, if confirmed, raises the problem of the contemporaneity of the Scottish and Wicklow mountain glaciations and the question of whether the fauna survived, however meagrely, into early post-glacial times. Probably extinction occurred, more or less completely, in the rigorous tundra phase after the Allerød period.

Dr. K. B. Blackburn, King's College, Newcastle, described two anomalous finds, one of *Trapa natans* in the Scottish Outer Isles, and one of the moose (*Alces Alces*) in the Tees Valley at Neasham. All they have in common is that both are now extinct in Britain, while both were present together in Cromer Forest Bed times.

The fossil *Trapa* nut was found entangled in floating *Potamogeton* debris in a loch in South Uist. The loch is brackish and connects to the sea-loch, Loch Eynort, by a tide-race 10 ft. wide and about 50–100 yd. long. The nut was dated by obtaining a pollen sample from adhering peat. 140 tree-pollen grains and some non-tree-pollens were obtained, and the spectrum constructed from them was matched with the longest peat profile diagram so far obtained in the neighbouring regions. The spectrum appeared to agree with a level about mid-Zone VII of the tentative zoning of the diagram. The two profiles, Stoneybridge and Calvay, both have an *Alnus* rise at the base which might be equated with the Zone VI–Zone VII transition to Atlantic times. The nut is assumed to be indigenous, since *Selaginella* and *Drosera* pollen occurred on the nut as in the Zone VII, and other zones of the diagrams, and, it may be added, in the local vegetation at present. No pollens were found on the nut that were not represented from the diagrams, and this also suggested that the nut had not been washed up Loch Eynort into Loch Ceann-a-bhaigh from the sea. A European distribution map for *Trapa* was shown.

The moose skeleton at Neasham fell out of a peaty band halfway up a brickpit face. This band is inferred to be a deep-water lake-mud. The sequence of deposits was as follows:

3. Clay.

2. { Upper peat.
Slightly laminated clay (locally known as 'prismatic' clay and generally considered to be a water-lain deposit).
Lower peat—Hypnum above, laminated below } (thinner towards side of section).

1. Clay.

In Raistrick's map of the distribution of late-glacial lakes ponded by the Cheviot Ice, one lake is shown over the Neasham district. A pollen diagram was made for the section. The lower peat shows high values for pine basally followed by high birch and willow and a reversion to high pine at the top. There is an increase in the alder curve in the upper peat which may mark the start of Zone VII. The central part, in which the moose was found, may be late-glacial; but the presence of high hazel values at the same level needs accounting for if the clay above is to be suggested as belonging to Zone III, and such correlations are scarcely justified at this stage. The present range of the moose includes the forested lake country of northern Canada.

Prof. Heslop Harrison's paper was read, in his absence, by Prof. Clapham. There are four elements concerned. The 'American' group of species such as *Spiranthes stricta*, *Eriocaulon*, *Sisyrynchium*, *Naias flexilis*, and the sponge *Heteromyelia Rylei*. This group is largely centred on the group of islands between the Outer and Inner Hebrides, Coll, Tiree, and Gunna, particularly the first-named. Secondly, the so-called 'Macaronesian' element including the moss *Myurium hebridarum*, which occurs in the Outer Isles in places, Coll, Tiree, and Eigg, in a non-fruiting state, its principal centre being the Canary Islands and the Azores. Another in this element is the water-beetle *Deronectes canariensis*. Thirdly, there is the development of the distinct Hebridean races of plants and animals common on the mainland, for example, wren, thrush and field-mouse and many insects; such plants as *Orchis hebridensis*, *Lonicera*, *Pericylmenum* var. *Clarkii*, *Rosa* spp. The fourth element is that of the arctic alpines.

All the problems have to be reviewed in relation to what is known, as yet, of the geological and geographical history of the whole group of islands during glacial and late-glacial times. There has been too much speculation about these regions up to the present, based on erroneous information or none.

Jehu and Craig considered some time ago the upper slopes, above 1,500 ft., of Bheinn Mohr in South Uist, to be unglaciated. The many changes of sea-level in glacial, late- and post-glacial times presume certain linkages and separations of the various island groups one with another, and with the mainland and Ireland. As regards such islands as Coll and Tiree, a not very extensive rise in former sea-level, for example, to the 100 ft. beach-level perhaps, would have been sufficient to submerge them completely, with consequent extinction of the flora and fauna. Similar extinction can be presumed for those islands that were completely glaciated at maximum or subsequent glaciations. Prof. Harrison openly admitted, however, that he has approached the problems with a bias towards a 100 per cent survival of flora and fauna. Pre-glacial raised beaches suggest the Hebrides to have been islands at the start of the Ice Age, presumably possessing a small flora representative of the rest of the mainland. To what extent this was overwhelmed, survived on nunataks, or migrated and afterwards immigrated, depends on glacial conditions at their maximum for each area. On Bheinn Mhor, South Uist, we find such plants as *Saxifraga stellaris*, *Sedum roseum*, *Oxryia digyna*, *Alopecurus alpinus* (this last nowhere else save on the mainland), *Silene acaulis*, *Carex capitata*, *C. bicolor*, *C. glacialis*, *Poa alpina*, *Arenaria gothica*, *Saussurea alpina*, and the mosses *Andrœa vittii*, *Ditrichum vaginans*, and *Myurium hebridarum*. Can we credit persistence of these plants here, and on mountains of similar heights in this and other islands, on ice-free ledges of high cliffs and nunataks, or possibly on land surfaces exposed by eustatic fall in sea-level? There is little glacial drift west of the exposed mountains on the Long Island, which may have been ice-free. Among faunal survivals are *Bombus* spp., *Salices*, the associated *Pontalia* and mites, and many spiders.

If the islands were cut off from the mainland after the last inter-glacial by an ice barrier, with no subsequent land connexion, we might account for the development of the Hebridean races. A previous connexion with the mainland during inter-glacial iso- and eu-static adjustments, allowing immigration to occur in the cases of those islands the floras and faunas of which had been overwhelmed at maximum glaciation previously, could be postulated. All this is hypothetical at the present state of our knowledge. *Campylopus Shoreii* and *Rubus* species may have immigrated with the Eu-Hebridean races and survived with them. Where the American element, absent from the Outer Isles, survived is a problem. Possibly on some ice-free area to the west of Ireland; the presence of *Eriocaulon* in inter-glacial deposits in the west of Ireland may be cited as indicative evidence. Presence before and after a glaciation without knowledge of other factors is not necessarily *a priori* evidence for survival, however, and the number of investigations of late- or inter-glacial deposits in the Western Isles is very small as yet.

The richness of the flora and fauna of the Inner Isles, in part, compared with that of the Outer Isles, was explained by assuming progressive west to east severance of land connexions. The Coll, Tiree group being cut off later, there was more time available for immigration.

Prof. Zeuner raised the question as to what evidence the geologist can supply towards reconstructing the ecological conditions during late-glacial times. The distribution of fossil soils shows a preponderance of solifluxion phenomena in the west, especially from the south of England and France, but east of the Rhine a dominance of loess types. With solifluxion on a frozen subsoil there may have been taiga conditions such as prevail to-day in Siberia. In the loess areas grass-steppe conditions with an absence of trees, except in the river valley bottoms, where the loess itself appears to be absent, may be conjectured. Between the loess and the Scandinavian ice there was a 10–100-km. wide belt, presumably of a tundra type, but differing from modern arctic types in its meteorological conditions. The radiation was possibly the same as that to-day for these latitudes, thus a richer flora and fauna may have been possible. The loess conditions disappeared after the Salpausselka stage, climate ameliorated, and the forest belt advanced northwards. Dr. Zeuner is opposed to the survivalists' theory of the Mediterranean and Lusitanian elements in Ireland and Scotland since the existence of the hypothetical land area between Ireland and Spain had never been proved, and he thought that to-day these forms just survived and could not have withstood the rigour of glacial conditions.

Mr. Wilmott assured the meeting that Lusitanian species do not merely just survive in Britain but also flourish from the mountains down to sea-level, although they may be ecotypes of species the southern forms of which could not survive. He cited an instance from a recent cold winter in which Irish forms of *Saxifraga umbrosa* in his garden survived but the Pyrenean forms were killed. He warned foreigners that in Britain they were dealing with the Atlantic climate, which could play many tricks. The Hebrides and Caithness are treeless, but this condition is governed by high winds and lack of snow cover in winter, not of temperature, and there is no tundra there. What degree of coldness did the presence of ice here really indicate ? He pointed out a similarity of British and Finnish floras even to-day.

Mr. C. Elton said that from a zoological point of view the Outer Isles, Shetlands, Isle of Man, etc., appear to have been separated from the rest of Britain since the last inter-glacial, since they lack so many, of the species common to the main island. Although the post-glacial vegetational history of Ireland seemed to imply a land connexion in the Holocene, this was inconceivable on zoological and geological grounds. Did man play a more important part than we have imagined up to the present ?

Prof. Jessen, replying to previous speakers, reaffirmed that Ireland in the late-glacial lay to the north of the forest limit. Whether 'tundra', or whatever else it might be called, it was treeless. *Arbutus* could scarcely have survived on a land surface between Ireland and Spain for, if it did exist, it must have been very oceanic and subject to high winds. *Arbutus* is a shelter-demanding species. Boreal species might have survived on nunatak areas in the south of England, but doubtfully Lusitanian species. The present distribution of *Trapa natans* is very sharply defined in the north-west of Europe to-day, in regions of Continental warm summers but immaterial winter conditions. He doubted if the 18° C. July isotherm ever existed in the Hebrides region in post-glacial times.

Dr. J. B. Simpson, who surveyed Coll and Tiree for the Geological Survey of Great Britain, was certain that they were completely glaciated at maximum glaciation. Glacial striæ occurred all over these islands at all heights. He wondered if human agency during the Viking period was responsible for any plant introductions. The Outer Isles were regular ports of call for galleys plying between Ireland and Iceland. Further, bird migrants, such as the shearwater, which goes south to the Canaries, might have influenced moss dispersal.

Prof. Faegri was somewhat against a Viking dispersal agency, as many of the species concerned, for example, *Arenaria norvegica*, *Carex bicolor*, were extremely rare even in Norway.

Dr. Farrington appealed to botanists to lay aside their speculations and instead seek to establish a reliable geological background for the phenomena of floral history. If the Welsh mountain ice proved to have been pushed about by Northern ice, then it must be earlier than the Wicklow Mountain glaciation. This was considered later than any major ice sheet in Ireland. If varying onsets were established for the different regions, the whole problem of the contemporaneity, at present assumed, was thrown into doubt. If the last glaciation was later than that in Denmark there was no discrepancy in the time for immigration of the floras to be explained. He stressed that the problem of contemporaneity of immigration assumes similar glacial and climatic developments in Ireland and in Denmark. There are good reasons for thinking that this is far from being the case and that local mountain glaciations occurred later in Ireland. During the Daniglacial and Gotiglacial stages it appears likely that there was a retreating ice margin in Scandinavia, but after the Salpausselka moraine stage the retreat was far more one of the decay of stagnant ice *in situ*. The Irish conditions are not yet clear. He asked, was the so-called Allerød oscillation contemporaneous or a stage in glacial retreat ?

Prof. Flörschutz (Holland) stated that *Trapa natans* was known from the primary and secondary inter-glacials and from Atlantic times, as a fossil, in Holland.

Dr. E. S. Brown contributed information on insect faunas in the Faroe Islands. In a certain species of Tipulid (cranefly), *T. pagana*, the females were wingless and therefore could not migrate by flight. Assuming the Faroes to have been islands since late-glacial times, how had this species colonized them ? Bird migration was an unlikely factor since the Tipulid eggs were produced in autumn when the birds were migrating southwards. Human dispersal by boat was also considered unlikely. On many different islands in the group, up to forty miles apart, another species occurred the females of which were practically wingless and in the same position, as regards migration, as *T. pagana*. Transport in hay was later suggested as a factor.

Dr. P. W. Richards suggested that Bryophytes may well prove valuable in the study of these problems. The British flora is particularly rich in relict species, for example, the liverworts, *Mastigophora Woodsii* and *Scapania nimbosa*, restricted to the Hebrides, Western Ireland and Western Scotland, and the moss, *Myurium hebridarum*, are probably pre-glacial relicts. None of these shows spore reproduction in its present station, except *Myurium* in the Canary Islands, and none has any means of vegetative reproduction. He considered bird dispersal of Bryophytes to be very improbable. Attention was directed to a British–Chinese element represented by *Mastigophora* with a disjunct distribution in Eastern Asia and the Hebrides. This is comparable to the Chinese–American flora, with only fossil representatives in Europe, for example, *Magnolia*. He suggested that Bryophyte representatives of these floras, with their small size and great tolerance of unfavourable conditions, might well have survived as relict species to-day. Prof. Jessen's conclusions on the oceanic nature of the late-glacial climate in Ireland were noteworthy. Such species of the arctic–alpine group, for example, *Paludella squarrosa*, with a relict southern distribution but fairly frequent in the north until drainage operations have caused it lately to diminish, has a very poor representation in Ireland. Could this be due to there never having been suitable conditions there for its establishment after glacial times ?

Dr. W. A. Clarke pointed out that the flora of Rhum stands somewhat apart from that of neighbouring islands, possibly due to the higher mountains, reproducing the non-glaciated upper slope conditions of Bhienn Mhor group, South Uist. Such plants as *Poa alpina*, *Saussurea alpina*, *Thlaspi alpestre*, and *Arenaria norvegica* are present in some quantity at only 1,500 ft. The nature of the summits and ridges with angular non-glaciated, but excessively frost-shattered, debris recalls Fernald's mountain top survival sites in Newfoundland. The moss *Myurium* is frequent up to the summit of Bheinn Mhor, South Uist, though the several expeditions to the Clisham area in Harris have not found it there also. He suggested that its lowlands stations were colonized afresh, after survival in the mountain regions, namely, *Myurium* on Ben na Hoe sea cliff, South Uist, mentioned by Prof. Harrison.

SCIENCE IN ADULT EDUCATION

By Dr. M. H. CLIFFORD

Board of Extra-Mural Studies, University of Cambridge

DURING 1946, full-time appointments of tutors to give extra-mural instruction in the natural sciences were made both by the University of Birmingham and by the University of Cambridge. The inclusion of natural scientists in the staffs of extra-mural departments is a development which reflects the increasing recognition of the importance of, and the growing demand for, the teaching of science to adults.

The Education Act of 1944 has charged local authorities with the duty of securing for their areas the provision of adequate facilities for further education. But in this undertaking they are required to consult with the university extra-mural departments and with the voluntary bodies, such as the Workers' Educational Association, which have built up traditions and developed practice in this field over very many years. The cost of lecture courses provided by these bodies is met in part by direct grants from the Ministry of Education amounting to not less than three-quarters of the lecturers' fees, subject to the classes conforming to regulations determined by the Minister. For the year 1944–45 approximately £105,000 was thus disbursed by the Ministry. Tuition is given in courses which vary in duration and in the level of instruction. Terminal and university extension courses usually extend to twelve lectures, while sessional classes normally include twenty-four lectures. Tutorial classes extend over three successive winter sessions, each session comprising twenty-four weekly meetings. In this provision for further education the representation of scientific subjects has been, and still is, very slight. During 1944–45 natural science courses in England, Wales and Scotland arranged by the Workers' Educational Association, either on its own or in co-operation with universities, amounted to not more than 4·5 per cent of the total number of courses in all subjects. This figure excludes courses in psychology (6·9 per cent of total) and in anthropology (0·2 per cent). These are customarily classed with the social sciences. In a large number of cases the approach to psychology is philosophical rather than experimental. The accompanying table records the provision of science courses during the last four sessions by the Board of Extra-Mural Studies of the University of Cambridge, having regard to the two sides of its work. Extension lectures are provided through local centres committees: tutorial and sessional classes are normally provided by joint action with the Workers' Educational Association.

Board of Extra-Mural Studies, University of Cambridge. Frequency of courses in natural sciences, 1942–46

Session	University extension courses			Tutorial and sessional classes		
	Total courses in all subjects	Courses in science*		Total courses in all subjects	Courses in science*	
		Number	Per cent of total		Number	Per cent of total
1942–43	74	1	1·4	28	3	10·7
1943–44	81	2	2·5	30	1	3·3
1944–45	93	1	1·1	63	5	7·9
1945–46	69	1	1·5	73	12	16·4

* Chiefly biology or the social relations of science.

In the latter connexion it will be observed that there has, during the last four years, been a marked expansion in the number, and, to a less extent, in the proportion, of courses in science. This growth can in part be correlated with the availability of certain tutors, chiefly biologists, and with a planned endeavour to discover reasons for the apparent lack of interest in science among adult students, an occurrence which did not correspond well with the known demand for popular books on scientific subjects. Certain aspects of that problem are discussed below.

To some extent, unfamiliarity with science on the part of organisers and administrators in adult education has put science courses at a disadvantage when, in company with more familiar alternatives such as literature, history and social studies, they have been set before potential student groups for choice to be made of a subject of study for the ensuing year. Secondly, there has been an insufficiency of scientific workers offering themselves as tutors, partly on account of indifference to the claims of such work, but also on account of an unawareness of its existence or an insufficiency of time to devote to its furtherance. Lastly, it would appear that not enough attention has always been given to the special needs, and the special limitations, of adult students by those who have been concerned with the teaching of science in extra-mural classes.

To-day it is likely that these last two groups of factors—namely, lack of scientific workers willing to teach in adult education, and lack of attention to the problems of teaching science in adult education—are the most important ones hindering the desired convergence of men of science and laymen in an educational partnership. Students and administrators, alike, are coming more and more to recognize the desirability of such a development, but great difficulty is being found in the provision of suitable tutors. At the present time the teaching of science within the area served by the Cambridge Board of Extra-Mural Studies could be at once expanded if more tutors were available, science courses having had to be refused on account of the scarcity of tutors. Men of science who are anxious that their work should not become divorced from the interest and understanding of the ordinary citizen have a responsibility to give this matter their urgent consideration. For the man or woman who has the necessary abilities this work, while often arduous, is most rewarding, not least on account of the extent to which tutors can learn from their students, both in matters of fact and in matters of outlook. Tutors' expenses are found and a fee is paid according to the type of class and the degree of experience of the tutor. Work is normally on a part-time basis, and no more than one class per week need be undertaken. Thus despite the pressure of professional work it should be possible for many more scientific workers to participate in this work than are doing so at present. Persons qualified in some branch of science who would wish to share in the task of bringing the scientific point of view to their fellow citizens should get into touch either with the extra-mural department of the nearest university, or with the central office of the Workers' Educational Association, 38*a* St. George's Drive, London, S.W.1.

The writer of this article has recently published (*Discovery*, Sept.–Oct., 1946) a fuller account of techniques found useful in the teaching of science to adults, a review of the problem which it is hoped will be of assistance to persons about to undertake work of this kind. Further, there is now an increasing tendency for extra-mural departments of universities to offer some opportunity of training to potential tutors in adult education. For example, in 1947 the Cambridge Board of Extra-Mural Studies will arrange, for the second year in succession, a fortnight's course for this purpose. It will be intended for persons with suitable academic qualifications who need advice about conducting adult classes and teaching their subjects therein. Advice about teaching methods will be given by experienced tutors, and there will be opportunities for meeting and giving practice talks to adult students. Background information concerning adult education and its development will also be given. Such courses do not claim to offer anything in the nature of a complete training, but they provide a valuable opportunity for would-be tutors to acquire some knowledge and personal experience preparatory to embarking upon an adult class.

In a short article it is only possible to consider very generally the part that science has to play in the education of adults, and the form in which it may most readily gain their attention. This is dealt with at greater length in *Adult Education*.

Experience in the area of the Cambridge Board of Extra-Mural Studies has clearly shown that, at the present time, for the majority of adults interested in adult education it is the approach by way of the social significance of science that is most successful in arousing interest, and in evoking the effort necessary for regular and effective attendance during a course of twelve or more lectures. While the social approach to science is far from being the only important one for the ordinary citizen, it is manifestly the approach of the moment. Scientific workers are accustomed to being opportunists in their own fields, doing what they can, when they can, and how they can. They would do well to employ similar tactics in bringing their subject to the notice of others.

In the hands of a skilful tutor the exposition of science in its social setting can lead to a more informed appreciation of the problems of citizenship, and to a more widespread understanding of the scientific method. Recognition of the fact that science is an activity distinguishable by its methods, rather than the simple pursuit of gadgets and cures, is still very rare among laymen. This situation is largely responsible for the continuance of the belief, still held by many, that science has no place in the liberal education of adults since it has no cultural contribution to make.

The social approach to science makes especial demands upon the tutor, who will need to be widely read outside his own subject, and able to recognize frankly his own vested interest in the scientific outlook. Tendentiousness will bring discredit upon those who practise it as tutors in an educational activity where emphasis is placed upon the need for objective inquiry on the part of students who are motivated by considerations of a practical and social character. To-day the frontiers between natural science on one hand, and psychology, economics, and philosophy on the other, are often vague and difficult of definition. This makes still greater the necessity for objectivity on the part of the tutor. Some men of science will consider it inappropriate to discuss these disputed fields in advance of a more complete study of them by the methods of science. But students will persist in bringing forward wide-ranging issues in which science is involved, such as, for example, the place of scientific method in the investigation of public opinion; the part to be played by science in the formation of opinion, both in propaganda and in education; the attitude of scientific workers to the concepts of creation, free will, democracy, and to the question of the mind–body relationship. Therefore, it would seem advisable that the tutor should be able to deal with such topics in the light of previous contemplation rather than impromptu. Scientific speculation, when self-confessed, can play an important part both in the establishment of new branches of science and in the general advancement of social awareness. It is a characteristic of adult education to be rich in demands for the study of subjects which, at present, do not fall conveniently into the conventional divisions of knowledge made by the universities for their own purposes. This is a fact the implications of which have not yet been very much explored by educationists.

Hitherto the demand for science courses of a more academic character has arisen only from a minority of adults. It is hoped that this demand will develop, both as a result of direct encouragement, and as a result of the more widespread introduction of students to science by way of the social approach. It must, however, be remembered that the intention of adult education is not to produce professional research workers; though there are a few scholarships enabling exceptionally qualified students to proceed from adult classes to full-time university courses. The hope is, rather, to increase understanding and to widen outlook. Consequently, the teaching methods employed will not necessarily coincide with those suitable for the vocational training of scientific workers. Experience suggests that it is usually better to build up the more academic type of treatment in relation to topics in which there is already some considerable amount of amateur activity. These may be matters of local interest, including natural history; or subjects with vocational aspects, such as gardening, home nursing, motor-car maintenance, or radio. Courses in biology have been very successful when based upon the interests of local field clubs. It is recognized that courses of this type must be as fully experimental as possible—a provision which in adult education still presents many difficulties from the point of view of organisation.

With respect to both of the routes by which science may be approached, whether social or academic, it is biologists who have made the greatest progress in the business of relating their material to the needs of the ordinary man. It has been said that this has largely resulted from the advantages which biology enjoys with respect to its subject-matter and its methods. With respect to methods, genetics is a department of biology that is to a great extent dependent upon mathematical techniques, and which, like physics and chemistry, is advanced by the use of symbols. Nevertheless, the popularizers of biology have to a considerable extent found it possible to include the subject-matter of genetics within their purview. So far as interest value is concerned, physicists and chemists have acquired a powerful pull on the public mind with the opening of the age of atomic energy. The success of certain carefully designed books expounding the physical sciences for the ordinary man leaves one with the impression that in lecture courses much could be done with similar subject-matter. Indeed, the experience, not only of an earlier generation but also of more recent years, is that public interest is keen if lecture courses on such topics are given by lecturers who have the necessary gift of lucid exposition and an ability to relate their subject-matter to the familiar experiences of everyday life. If more physical scientific workers of the present generation would devote time to discovering, by trial and error, techniques suited to the popular exposition of their subjects through the spoken word, these sciences might within a few years come to be as much in demand as the biological sciences.

But experience in adult education suggests that it is not necessary, nor even desirable, for lecturers in science to confine themselves too narrowly within their own research subjects, any more than occurs with school teachers or schools' examiners. Scientific workers when participating in adult education are not authorities addressing their professional equals, but expositors serving the needs of laymen. Their position closely resembles that of the political commentator attempting to assist public understanding of current affairs. Indeed, they may even prove to be more effective as tutors if they can share some of the difficulties experienced by their students when surveying the territory of science. To-day, scientific workers are presented with great opportunities in the field of adult education. Are they willing and ready to take advantage of them ?

THE INTERNATIONAL UNION OF PHYSICS

ACTIVITIES OF THE UNION, 1923-39

AT the close of the First World War, the main pre-war international scientific organisations, some of which had been dominated by Germany, had collapsed. It was therefore decided to create a series of scientific unions to promote international co-operation. The Union of Pure and Applied Physics was formed at the end of 1923. In 1934 the Union held its most important assembly of the inter-war period. At this assembly, which was held in London, it received a report from the Commission on Standards, Units and Nomenclature which it had previously established. It approved recommendations concerning (*a*) thermal units, (*b*) units and nomenclature of electromagnetism (including the adoption of the 'oersted'), and (*c*) the nomenclature of thermodynamics. It decided that the Commission should continue its work, and should (i) co-operate with other international bodies in relation to definitions of terms, (ii) prepare lists and definitions of terms occurring in two or more branches of physics, and (iii) assist those who, in any country, are preparing such lists. The Commission was not intended to conduct technical investigations, such as those guided by the International Commission on Illumination. It was to receive and to review data prepared by technical commissions and to decide whether to recommend their general adoption by physicists. Associated with the 1934 Assembly was a public conference, including sections on (*a*) nuclear physics, and (*b*) the solid state. This very successful conference was held jointly with the Physical Society of London, which was mainly responsible for the organisation.

The work of the International Union of Physics may fairly be compared with that of some of the other unions which are also members of the International Council of Scientific Unions. The International Astronomical Union united thirty-four standing committees and organised many important research projects. The Union of Geodesy and Geophysics was also very active. On the other hand, the projected Union of Biological Sciences never achieved biological existence ! The International Union of Pure and Applied Physics was useful—but in a limited way. One reason for its rather slight activity was that its constituent members, the national committees, were not very active in any country, and were non-existent in many.

The Assembly in Paris, January 1947

Against this background we may now consider the recent assembly held at the Sorbonne with Prof. M. Siegbahn (Sweden) as president. The secretary was Prof. P. P. Ewald (Belfast). He had undertaken the office, at the request of the president, after the death of Prof. Abraham, who had been secretary since 1923. The local arrangements were made by Prof. Fleury (director of the Institut d'Optique). The conference recognized that it owed more than a formal vote of thanks to Prof. Ewald and Prof. Fleury, whose hard work in very difficult circumstances enabled it to function smoothly. The following countries were represented: Australia, Belgium, China, Czechoslovakia, Denmark, France, Finland, Great Britain, Italy, Netherlands, Norway, Poland, Spain, Sweden, Switzerland.

From this list it may be seen that Western Europe is well represented, and there were also some scientific workers from Eastern Europe, although the U.S.S.R. did not accept the invitation to attend. It is hoped that the causes which prevented the representation of the United States, Canada and India are purely temporary, and that they will send delegates to the next assembly. It was suggested that ex-enemy States may also be invited as soon as peace treaties have been signed.

Apart from the necessary business of electing new officers, etc., which will be dealt with later, the chief discussion centred on the future policy of the Union. There were two chief schools of thought. The first view (sponsored by the Dutch delegation) was that the assembly should give a strong lead by appointing a large number of commissions to organise international co-operation in various branches of physics. It was urged that if this were not done, various organisations independent of the International Union of Physics would come into existence. Already a Union of Applied Mechanics and a Union of Crystallography have been formed. The Réunion des Opticiens held in Paris in October appointed a continuation committee to organise international co-operation in optics. This committee is at present willing to work as part of the International Union of Physics if possible. The Dutch delegates urged the formation of Commissions for Optics, Nuclear Physics, Low Temperatures, Magnetism, Metals, Spectrum Analysis, Cosmic Rays, Crystallography and Mechanics. On the other hand, some delegates felt that an attempt to 'organise physics from above' would certainly fail. Co-operation must be a matter of organic growth. It was believed that all the International Union can do is to recognize an urge for co-operation among a group of workers when it occurs spontaneously (as had happened with optics) and give the support of the Union.

Clearly, either of these arguments pushed to extremes must lead to absurdity. Too ambitious a programme at present would lead to a cumbersome international 'organisation' with nothing to organise. On the other hand, if the Union always waited for sections to make their plans complete, those in favour of co-operation would form separate unions, and the Union of Physics would lose its *raison d'être*. The British delegates suggested that physical sciences can, for purposes of international co-operation, be divided into two groups. The first group includes subjects such as cosmic rays and physics of the atmosphere, in which observations made at different parts of the earth's surface are complementary. An international organisation of those branches of physics may expect to undertake important projects of research which no one country could organise. The second group includes subjects such as optics and acoustics, which are concerned with the measurement of quantities which do not vary with latitude and longitude. International projects of research are likely to be less important in these subjects—though they are not impossible. Both groups of sciences may expect to benefit from international discussion of units and nomenclature and from personal contacts. On this view the International Union should establish commissions where important research projects are possible, and also where there is evidence that workers in a certain branch of physics would welcome the formation of a commission. It was decided to establish the following commissions :

(1) *Cosmic Rays :* to study the possibility of international co-operation in observations. *Chairman :* J. Clay ; *Secretary :* P. Auger ; *Members :* P. M. S. Blackett, W. Heitler, B. Gross, B. Rossi.

(2) *Units of Radioactivity :* to consider the proposals of Condon and Curtiss (see *Rev. Sci. Instr.*, June 1946). *Chairman :* E. U. Condon ; *Members :* L. F. Curtiss, Sir Charles Darwin, E. Evans, J. C. Jacobsen, Mme. Joliot, M. Siegbahn, C. G. J. Sizoo.

(3) *Symbols, Units and Nomenclature :* to continue the work of the former commission. *Members :* P. Fleury, Ezer Griffiths, A. Pérard, Van Dijk.

(4) *Thermodynamics :* to study the definitions and nomenclature of thermodynamics and thermochemistry and to co-operate with the Commission on Standards, Units and Nomenclature, and with the International Union of Chemistry. *Members :* E. Bauer, De Boer and E. A. Guggenheim.

(5) *Optics :* to form a preparatory commission to consult the Optical Groups of various countries on the best way to bring the organisation proposed at the Réunion des Opticiens (held in October) within the framework of the International Union of Physics. The members of the preparatory commission are to co-opt persons chosen by the Optical Groups in each country so as to form a fully representative commission, the full commission to meet at an early date (probably in June at Prague). *Secretary :* P. Fleury ; *Members :* R. W. Ditchburn, J. Hrdlička, E. Perucca and A. C. S. Van Heel.

The conference also appointed representatives on joint commissions dealing with (*a*) physico-chemical data, (*b*) viscosity, (*c*) the ionosphere, (*d*) radio-meteorology.

The Assembly elected Prof. Kramers as president, Prof. Fleury as secretary and Prof. Pérard as treasurer. A number of vice-presidents, including Sir Charles Darwin, were also elected. The officers form an executive committee to act until the next assembly. The executive has power to form further commissions if there is evidence that this is desired. Any suggestion for the formation of a new commission or for any other project of international co-operation may be made to the executive through a national committee for physics.

Relations with the United Nations Educational, Scientific and Cultural Organisation

The Assembly received a report of an agreement between the United Nations Educational, Scientific and Cultural Organisation and the International Council of Scientific Unions. Under this agreement the Organisation recognizes the International Scientific Unions as "providing a natural form for the international organisation of science". It agrees to help them financially in regard to (*a*) international research projects, (*b*) travel expenditure, and (*c*) provision of office space, secretarial service in arrangement of meetings, etc., but *not* the general secretarial expenses of the Unions. It is expected that in conjunction with the Organisation the International Union of Physics may undertake the compilation of panels of experts in every branch of physics and, later, the publication of an international directory of physics. This directory is to include lists of laboratories with the names of workers and types of research. Other projects discussed include the publication of 'handbooks' of a type too expensive for one nation and the establishment of archives (that is, records, such as manuscripts, films, etc., of experiments and of persons of historical importance).

It was recognized that the details of co-operation with the United Nations Educational, Scientific and Cultural Organisation must be worked out gradually over a period of years; but it was felt that the agreement with the Organisation alters the whole outlook of the International Unions. They should now have sufficient funds for all useful work which lies within their terms of reference, and the backing of a permanent secretariat and a permanent organisation.

The Assembly decided to meet again in September 1948 in Holland. The interval is shorter than the usual interval of three years between meetings of the assembly, but a fairly early meeting is desirable to review the working of the new commissions and to make any alterations in statutes which may be needed to secure the full benefit of co-operation with the United Nations Educational, Scientific and Cultural Organisation.

Conclusion

May I conclude this article on a note of optimism —*restrained* optimism, but still optimism—concerning the future of the Union. The Paris Assembly was a friendly conference and its programme, although not excessively ambitious, is practical. Each of the commissions exists to meet a demand—and has therefore a definite and natural field of reference. It may be that more commissions ought to have been set up, but if the demand for this or any other useful action arises before 1948, the executive can act. Finally, the agreement with the United Nations Educational, Scientific and Cultural Organisation offers the prospect of achieving stable and permanent co-operation in science. The extent of this co-operation may be expected to grow. The rate of growth will depend on the support received from national and local scientific societies and from individual scientific workers.

R. W. DITCHBURN

OBITUARIES

Dr. Alexander Scott, F.R.S.

At the great age of ninety-three, Dr. Alexander Scott died at Ringwood, Hampshire, on March 10. He was educated at Selkirk Grammar School, of which his father was rector, and at the University of Edinburgh, where he took first place in chemistry. In 1875 he became assistant to the Jacksonian professor at Cambridge, and having been awarded a Clothworkers' Exhibition in 1876 and a foundation scholarship of Trinity College in 1878, he gained a first class in the Natural Sciences Tripos in 1879.

From 1884 Scott spent seven years organising the teaching of science in Durham School and Middlesbrough High School. It was while here that Scott found the teaching of science in poor case, being handicapped by science masters either ill-trained or having to subordinate their efforts to preparing their pupils for answering the highly specialized questions of scholarship examinations. In his presidential address to the Chemical Society in 1916, the opportunity for successful careers for science students is compared with the rewards open to classical or mathematical students, and an appeal is made for a change in outlook. Whatever our views may be as to the early concentration on purely scientific subjects, it must be allowed that some progress has now been made in the betterment of the position of the scientific man.

Returning to Cambridge in 1891, Scott resumed work under Dewar, the Jacksonian professor, but five years later removed to London, where he became superintendent of the Davy Faraday Research Laboratory of the Royal Institution (1896–1911), Dewar being director. This Laboratory had been provided by Dr. Ludwig Mond in 1896 to afford opportunities for skilled men with the wish and time to devote to the solution of important problems.

Here Scott for fifteen years devoted himself to chemical work, which he pushed to the highest degree of accuracy, in his determination of atomic weights and of fundamental ratios such as that between hydrogen and oxygen.

Impressed by the accuracy of the work of Stas and by the view of that chemist of the illusory character of Prout's hypothesis—that the atomic weights of the elements are multiples of that of hydrogen—he remarks in his second presidential address to the Chemical Society that under its spell everyone falls who engages in work on atomic weights. This spell had certainly its influence on Scott, who by his skill and critical faculty clearly showed that Prout's hypothesis, in its original acceptation, could not be maintained; but he held that no work undertaken to determine the atomic weight of any element has led directly or indirectly to such an "increase in natural knowledge" as that centring around nitrogen, on which he did much careful work. Before the subject was cleared up by the discovery of isotopes, Scott in 1917 looked forward "to future investigation to focus out what is the true expression underlying Prout's principle", so that it would "lose its character as a will-of-the-wisp which it had borne in the eyes of so many distinguished men for a hundred years".

In his position as superintendent of the Davy Faraday Research Laboratory, Scott's relations with the workers there were amicable and helpful; many of them are now well known for the researches which they completed during their stay or as a result of further labours after leaving. Among them were Horace T. Brown, H. Debus, A. Liversidge, A. Mallock, Hugo Müller, Joseph Petavel, Charles E. S. Phillips, P. C. Ray, W. J. Russell, G. Senter and H. T. Tizard. Intolerant of slipshod work, Scott held the respect of his staff and showed a kindly friendliness to the sincere worker, a phrase used recently by one of the workers of that time now with us.

Scott was secretary to the Chemical Society (1899–1904) and treasurer (1904–15), much to the benefit of that Society; during 1915–17 he was its president. He was elected into the Royal Society in 1898, and elected a member of the Athenæum under Rule II in 1923. In 1906 he married Agnes Mary, daughter of Dr. W. J. Russell, F.R.S., and leaves no family. Robert Robertson

I first met Dr. Scott when he was seventy-one years of age: erect, with an imposing presence and an immense fund of scientific knowledge; critical, but, as I was to discover, with a capacity for kindness and friendship which can seldom have been surpassed. In 1919 he was invited by the Department of Scientific and Industrial Research at the instance of the Trustees of the British Museum to prepare a report on the condition of museum objects subsequent to their storage in a war-time repository. In accordance with his recommendation, a research laboratory was established at the British Museum, and he was director there until his retirement in 1931. I had the honour to be his assistant. During this period he made various important contributions to restoration work in the fields of archæology and painting, and such studies were his absorbing interest until the last.

Scott was particularly fitted to make these investigations. His career of service to chemistry had by no means precluded ancillary studies: he was a keen botanist and was prepared to tackle almost any inquiry in his private laboratory at home, from the most exacting work on atomic weights to the microscopical identification of plant structures. He was interested in solving problems for their own sake and could not resist the urge to experimentation. Thus it was that his advice was sought by all and sundry, and it was given generously and gratuitously.

He visited Luxor in 1923 and co-operated with Dr. Howard Carter and his chemical advisor, Alfred Lucas, in the prodigious task of organising the preservation of the objects from the tomb of Tut-ankh-Amun discovered the previous year—a task which was, as all the world knows, accomplished in the most trying circumstances with outstanding success.

It can have fallen to few to live the full life of service to science described above by Sir Robert Robertson, and to go beyond this and find time and energy in his latter years to become an authority of international repute in an entirely new field. If for nothing else, the name of Alexander Scott will be remembered for his pioneer work in inculcating the laboratory idea in museums: the recent development of this section of museology both in Great Britain and abroad bears testimony to his vision and judgment.

In the quality of his accomplishments Scott was a great man. He was, in addition, a notable benefactor to scientific research and, in my own knowledge, he helped many to a settled and happy life. He lived for science and truth, and found in this creed the formula of happiness. H. J. Plenderleith

Sir Joseph Barcroft, C.B.E., F.R.S.

On March 21 Sir Joseph Barcroft died suddenly at Cambridge from a heart attack. He had been hurrying to catch the bus which took him home from the Physiological Laboratory; he was seventy-four, and arthritis had begun to make cycling difficult, but this was the only sign that he was no longer as vigorous as ever. His occasional lectures were no less stimulating, he was an inspiring chairman of the newly formed Nutrition Society, an active member of countless committees, and after fifty years of research he could still open up unexplored fields and arouse the enthusiasm of the students who crowded his laboratory. He had just finished his yearly researches on the embryo sheep and had seen the publication of his new volume on fœtal physiology, "Researches on Pre-Natal Life" (see review by Dr. F. H. A. Marshall in *Nature* of March 22). He would have faced retirement philosophically; but his friends may be glad that he had no need to become inactive.

Barcroft was born on July 26, 1872, son of the late Henry Barcroft, of Newry, Co. Down. His family were Quakers, settled in Ireland since the seventeenth century, and their way of life must have been partly responsible for his calm but unrelenting pursuit of knowledge. He went to Bootham School, York, and then to the Leys School, Cambridge, entering King's College, Cambridge, in 1894. After a first class in both parts of the Natural Sciences Tripos he became demonstrator in physiology to Prof. Langley. In 1915 and again in 1939 he left academic physiology to work on the problems of gas warfare, but the rest of his life was spent in Cambridge, as professor of physiology from 1925 until 1937, and as director of the Agricultural Research Council Research Unit in Animal Physiology from 1941 onwards.

His work in physiology was always that of a pioneer; he had a genius for finding uncharted territory even in the most familiar regions, and for solving well-worn problems by an approach at a new angle. There are three major fields in which his work is classical: the physical chemistry of oxyhæmoglobin, the distribution of the blood between the storage depots and the circulation, and the physiology of fœtal life. In all three he set the fashion in current physiological research, but though many workers came to him for inspiration at each stage in his scientific career, he refused to become the specialist, and moved on as soon as he was satisfied that the main outlines were settled. He settled them by simple methods and simple ideas, leaving the complexities to be cleared up by those who understood them, but very rarely misjudging the main issues. He had, in fact, a wide range of scientific knowledge at his disposal and was at home with physical and chemical as well as biological ideas; but he knew the plain speech of the Quakers and wrote and spoke as a plain man with no claim to superior learning. He used to quote with delight the tribute of a foreign physiologist who said: "I like your book, Barcroft. It is so clearly wrotten!"

Besides their clarity, Barcroft's books are written with an engaging friendliness. They speak of yachting, travel and companions as accessories to physiological research, and no one who reads them will wonder at the constant stream of young men who came to him for training and encouragement. He was never at a loss for problems suited to the beginner or to the senior colleague; he knew where to go for help when some new technique was needed, whether its home was in Cambridge or abroad, and he could always attract a small army of collaborators when one of his major investigations was afoot.

Many honours came to Barcroft, including the Copley Medal of the Royal Society. Though he worked very hard, he was never too busy to help those who came to him for advice, and many did so. He could be relied on to introduce a speaker or propose a toast with a charming blend of humour and good sense, and in a private gathering he was the best of company. His sturdy figure will be greatly missed at the forthcoming International Congress of Physiology, for he had become one of the elder statesmen of the science, although he was never out of touch with the rank and file. There must be laboratories in all parts of the world where Barcroft will be remembered with esteem and affection for his personal qualities even more than for his great achievement as a physiologist. E. D. Adrian

---

We regret to announce the following deaths:

Mr. W. J. Bean, C.V.O., formerly curator of the Royal Botanic Gardens, Kew, on April 19, aged eighty-three.

Dr. J. D. Falconer, formerly director of the Geological Survey of Nigeria, on April 16, aged seventy.

NEWS and VIEWS

Reports on Penicillin

The Medical Research Council, acting on the advice of its Committee for Penicillin Synthesis, is making available for consultation by interested persons a number of reports on penicillin. In October 1943, when many of the structural features of the penicillin molecule were becoming clear through the work carried out in Great Britain, the problem of the synthesis became a pressing one, and to handle this aspect, the Medical Research Council set up a Committee for Penicillin Synthesis "to initiate, co-ordinate and make investigations on the synthesis of penicillin and analogues". At the same time the Committee for Medical Research of the Office of Scientific Research and Development in Washington, which had already undertaken the co-ordination of chemical work on penicillin in the United States, came to an agreement with the Medical Research Council for an exchange of information on anything which had a bearing on the problem of the synthesis of penicillin. The confidential reports which were issued and exchanged are known in Great Britain as the C.P.S. reports. A number of reports known as the Pen. reports and sponsored by the Therapeutic Research Corporation of Great Britain contain much information of historical value on the earlier work carried out on the structure of penicillin.

All these reports, together with others sponsored by Imperial Chemical (Pharmaceuticals) Ltd., Merck and Co. Inc., and the Squibb Institute for Medical Research, are now available for consultation in certain libraries in Great Britain. In the London area the reports may be consulted in the libraries of the Royal Society; National Institute for Medical Research; British Drug Houses, Ltd.; Glaxo Laboratories, Ltd.; Wellcome Chemical Research Laboratories, Beckenham; May and Baker, Ltd., Dagenham; and in the provinces in the libraries of the Universities of Birmingham, Bristol, Cambridge, Glasgow, Manchester and Oxford. In the Nottingham area the reports may be consulted in the library of Boots Pure Drug Co., Ltd. The information contained in these reports cannot be made the subject of any publication before the Penicillin Monograph appears later in the year.

Biochemistry at Guy's Hospital Medical School: Prof. R. H. S. Thompson

THE appointment of Dr. R. H. S. Thompson to the new University chair of chemical pathology at Guy's Hospital Medical School, London, is no surprise to those acquainted with his work. During the course of a distinguished career, he has been concerned in some twenty-nine publications covering several aspects of biochemistry. As a Millard scholar of Trinity College, Oxford, he early showed promise and became senior demy of Magdalen College in 1933. At this time he worked with Prof. R. A. Peters upon the role of vitamin B_1 in the metabolism of pyruvic acid in brain; extending the work (with R. E. Johnson) to the important observation, now applied clinically, of increased pyruvic acid in blood in the terminal conditions of this deficiency. Following this, as a scholar at Guy's Hospital, he was awarded the Laidlaw Prize in 1937 and published research with Prof. G. Payling Wright on the chemistry of Gaucher's disease. As the Adrian Stokes travelling fellow, working with Dr. Dubos at the Rockefeller Institute in New York (1937–38), he published work upon the important enzyme ribonuclease, and upon the production of experimental osteomyelitis. Upon his return to Oxford in 1938, he became University demonstrator in biochemistry and fellow and tutor of University College. Since 1946, he has acted as dean of the Medical School. At the outbreak of the War he joined the team working upon antidotes to the war gases under the direction of Prof. Peters and took a prominent part with Dr. L. A. Stocken in the discovery and development of British anti-lewisite (2-3 dimercaptopropenol). He has also been much concerned with the clinical developments of this substance and is now acting as secretary of the Medical Research Council Conference on *B.A.L.* During the War he also co-operated with Netley Hospital in the nutritional treatment of post-arsphenamine jaundice, and in 1944–46 was attached to the Australian Army as Major, R.A.M.C. He was awarded in 1943 the Radcliffe Prize for medical research, Oxford.

University College, Nottingham: School of Agriculture

THE Midland Agricultural College at Sutton Bonington has become the University College of Nottingham School of Agriculture. The Midland Agricultural College has had a long and distinguished association with agricultural and dairying education. The agricultural section started as the agricultural department of University College, Nottingham, in 1892. In 1895 the Midland Dairy Institute was established at Kingston-on-Soar, and in 1900 the agricultural department was moved out into the country to link up with the dairy side. The subsequent development of the Midland Agricultural College was due very largely to the four local county councils of Derbyshire, Leicestershire, Lindsey and Nottinghamshire. In 1942 the governing body made recommendations to the associated county councils that the immediate needs of agricultural education could be served by the development of farm institutes in the counties and that the College should be reserved for higher agricultural education and research; in 1943 the University College of Nottingham instituted a Faculty of Agriculture and Horticulture, and the principal of the Midland Agricultural College was appointed to the staff of the University College as the professor of agriculture. University College, Nottingham, has bought out the county council interests in the Midland College, and the money will be used by the councils in the development of county farm institutes.

The entire staff of the Midland Agricultural College is being transferred to the staff of the University College of Nottingham. Prof. H. G. Robinson, who has been at Sutton Bonington for twenty-two years and for the last twelve years as principal, becomes the first director of the new School of Agriculture. The present student population in the Faculty of Agriculture and Horticulture numbers 240. Developments envisaged at Sutton Bonington in the near future provide for a considerable extension of the facilities in the Horticultural Department. A scheme costing £15,000 has been approved in this connexion and is being assisted by the Ministry of Agriculture. As a result of this development, Nottingham will have a centre of higher agricultural education that will fit into the general scheme of agricultural education that is now being planned for the country as a whole. So far as horticulture is concerned, Nottingham will have to cater for the educational needs of the northern half of England.

Birds of Heligoland

MINOR discharges were used to arouse the seabirds of Heligoland so as to avoid their destruction in the greater explosions which marked the destruction of the fortifications of the island. The island is to revert to its pre-war use as an ornithological centre for migration studies. The nesting birds of Heligoland are comparatively few: its importance in the North Sea off the Elbe estuary lies in the facilities it has offered for the study of bird migration during spring and autumn. The Heligoland design of bird recovery trap, originally adapted for bird-ringing pursuits off South Wales, is being utilized in the formation of a chain of independent bird-study stations around the British Isles at Fair Island, the Spurn, Lundy Island, Milford Haven and elsewhere. As many as 9,000 starlings were caught, marked and released on Heligoland during one pre-war migration in the studies organised by the German State Biological Bureau under the direction of Dr. Rudolf Drost and Dr. Shildmacher. In nine days on one occasion 1,130 birds were ringed: these included 271 blackbirds, 220 song thrushes, 105 redbreasts and 144 skylarks. The German Ministry of Agriculture helped to finance these studies.

German Scientific and other Periodicals

THE Association of Special Libraries and Information Bureaux has prepared a classified list of German periodicals, excluding newspapers, official gazettes, local organs of political parties, trade unions and churches, devotional literature and popular periodicals (from the Association, 52 Bloomsbury Street, London, W.C.1. 1s.). The list is largely based on two published bibliographies, "Die deutsche Presse, 1946" and "A Check-list of Current Serials in the United States Zone of Germany". Orders for such periodicals for not less than six months subscription will be accepted on behalf of H.M. Stationery Office by the Secretary, Enemy War-time Publications Requirements Committee, Control Commission for Germany and Austria, Norfolk House, St. James's Square, London, S.W.1 (see also *Nature*, March 15, p. 366).

Spectrographic Terminology

THE Spectrographic Discussion Group at Glasgow has produced a pamphlet (University Press, Aberdeen, 1946) entitled "Suggested Definitions of Terms used in Spectrographic Analysis". This recommends a set of symbols for various spectrographic constants and suggests definitions of a large number of terms used in this type of work. The chairman of the group, Mr. S. D. Steele (c/o Messrs. Babcock and Wilcox, Renfrew, Scotland), offers to send a free copy of the pamphlet to interested persons and will welcome criticism and suggestions. The proposed symbols do not, in general, appear to conform to the principles laid down by the Joint Report of the Chemical, Faraday and Physical Societies (1937).

Fourth International Congress for Microbiology

THE International Association of Microbiologists is organising the Fourth International Congress for Microbiology, to be held at Copenhagen during July 20–26, 1947. General meetings will be addressed by Dr. F. C. Bawden (Rothamsted Experimental Station) on viruses, Prof. S. A. Waksman (New Jersey State Agricultural Experiment Station) on antibiotics and life, Prof. C. H. Werkman (Iowa State College) on the assimilation of carbon dioxide, and Prof. Ø. Winge (University of Copenhagen) on yeast in modern genetics. The nine sections of the Congress will be devoted respectively to general microbiology, medical and veterinary bacteriology, viruses and virus diseases, serology and immunology, variation and mutation in micro-organisms, plant pathology and mycology, soil and water microbiology, dairy and food microbiology, and industrial microbiology. The president of the Congress is Dr. Th. Madsen; and the honorary general secretary is Dr. M. Bjørneboe, Kommunehospitalet, Copenhagen. Those wishing to take advantage of official arrangements for hotel accommodation should communicate with the honorary general secretary not later than May 15.

Institute of Industrial Administration Summer School

THE Institute of Industrial Administration has arranged a summer school for 'management teachers', to be held at Oriel College, Oxford, during July 26–August 2. The purpose of the School is to give selected persons, responsible for the teaching of management subjects (full- and part-time), an opportunity to explore the syllabuses proposed by the Ministry of Education Committee on Education for Management and to discuss the practical teaching problems arising from it. The School will be residential and will be conducted in lecture and tutorial sessions. The chairman of the School is Major L. Urwick, chairman, Ministry of Education Committee on Education for Management. Guests will include delegates from the United States to the Eighth International Congress for Scientific Management, Stockholm, in July. The Ministry of Education will be represented, and the 'Assembly' address will be delivered by Sir David Ross, provost of Oriel College. Application for forms and programmes should be made to: Assistant Secretary (Education), Institute of Industrial Administration, Artillery House, Artillery Row, London, S.W.1.

Summer School in Relaxation Methods

A SUMMER school in 'Relaxation Methods' will be held at the Imperial College of Science and Technology, London, during the four weeks July 8–August 1. It would seem that there is no great difficulty in acquiring such knowledge of the relaxational technique as is required to solve ordinary engineering problems (frameworks, electrical networks, etc.), so it is proposed this year to concentrate on problems involving partial differential equations in two independent variables. The course will consist of more or less formal lectures, with numerous examples to be solved under supervision; lectures will be given on Tuesdays–Fridays only, but facilities for practical work will be also provided on Mondays and (if requested) on Saturday mornings. Further particulars can be obtained from Mr. D. N. de G. Allen, Imperial College, London, S.W.7.

School of Cosmic Physics, Dublin

THE inaugural meeting of the School of Cosmic Physics in the Dublin Institute for Advanced Studies was held on March 27. The following have been appointed by the President, on the advice of the Government of Eire, to be senior professors of the School: Dr. L. W. Pollak, senior meteorological officer, Department of Industry and Commerce, Eire (from April 1); Dr. L. Jánossy, I.C.I. fellow at the University of Manchester (from July 1, 1947); and Dr. H. A. Brück, assistant director, Cambridge Observatory (from October 1, 1947).

University of London: Appointments

THE following appointments in the University of London have been announced: Prof. S. W. Wooldridge, professor of geography at Birkbeck College, to the University chair of geography tenable at King's College, as from October 1; Dr. P. R. Crowe, senior lecturer in geography in the University of Glasgow, to the University readership in geography tenable at Queen Mary College, as from October 1; Dr. Alfred Schweitzer, lecturer in physiology in the University of Leeds, to the University readership in experimental physiology tenable at University College, as from October 1; Mr. A. W. Skempton, senior lecturer in civil engineering at the Imperial College of Science and Technology, to the University readership in soil mechanics tenable at the College, as from October 1, 1946; Mr. J. R. Gilmour, to the University readership in morbid anatomy tenable at London Hospital Medical College, as from October 1. The title of professor of mathematics in the University has been conferred on Dr. W. G. Bickley, in respect of the post held by him at the Imperial College of Science and Technology.

Colonial Service Appointments

THE following appointments have been made in the Colonial Service: Capt. C. N. Coombes, agricultural economist, Gold Coast; W. B. Tevendale, geologist, Gold Coast; Flight-Lieut. K. V. W. Nicholls, meteorological officer, Malaya; Flight-Lieut. R. C.

Bannister, professional assistant, Royal Observatory, Hong Kong; G. J. Lockley, fishery officer, Tanganyika; H. E. C. Lushington, senior assistant conservator of forests, Ceylon, to be conservator of forests, Ceylon; E. W. March, assistant conservator of forests, Ceylon, to be conservator of forests, Jamaica; L. G. T. Wigg, assistant conservator of forests, Tanganyika, to be senior assistant conservator of forests, Tanganyika.

Recent Comets

COMET RONDANINA–BESTER (1947*b*) was discovered by Rondanina and independently by Bester at Bloemfontein on March 24. Its magnitude at the time of discovery was 11, and its daily motion was rather rapid, suggesting that it was fairly close to the earth. Dr. L. E. Cunningham computed an orbit and a short ephemeris which has been continued by Dr. G. Merton; these are given below.

Comet Bečvář (1947*c*) was discovered on March 27 by Dr. Bečvář, Observatory Skalnaté Pleso. He described it as diffuse, without central condensation or nucleus, and its magnitude was 9. Dr. Cunningham has computed an orbit and ephemeris for this comet also, the ephemeris having been extended by Dr. Merton.

The Night Sky in May

FULL moon occurs on May 5d. 04h. 53m. U.T., and new moon on May 20d. 13h. 44m. The following conjunctions with the moon take place: May 6d. 00h., Jupiter 0·4° N.; May 18d. 09h., Mars 2° N.; May 18d. 10h., Venus 1° N.; May 24d. 23h., Saturn 4° S. In addition to these conjunctions with the moon, Venus is in conjunction with Mars on May 17d. 12h., Venus being 1·0° S. Mercury is in superior conjunction on May 15. Towards the end of the month, the planet sets 1½ hours after the sun and can be seen as an evening star. Venus rises about half an hour before the sun on May 1 and 50 min. before sunrise on May 31, and can be seen in the eastern sky, stellar magnitude −3·3. Mars can be observed as a morning star for a short period before sunrise, rising at 4h., 3h. 21m., and 2h. 41m. at the beginning, middle and end of the month respectively. Jupiter, in the constellation Libra, is visible until the early morning hours, setting after sunrise during the first half of May. Saturn, in the constellation Cancer, can be seen only during the early part of the night, setting at 1h. 36m., 0h. 43m., and 23h. 43m., at the beginning, middle and end of the month, respectively. Only one occultation of stars brighter than magnitude 6 takes place in the month, on May 23d. 22h. 10·5m., *A* Gemi. (*D*). The latitude of Greenwich is assumed, and *D* refers to disappearance. A total eclipse of the sun on May 20 is visible over portions of South America and central Africa, and preparations have been made to observe it (see *Nature*, March 1, p. 287); the British expedition has been cancelled following the deaths of two of the party in an aeroplane crash.

Announcements

THE Lord President of the Council has approved the appointment of Dr. Franklin Kidd, superintendent of the Low Temperature Research Station, as director of food investigation, Department of Scientific and Industrial Research, in succession to Dr. C. S. Hanes, who has become head of a unit of biochemistry that is being set up at the University of Cambridge by the Agricultural Research Council. Dr. E. C. Bate-Smith, senior principal scientific officer at the Low Temperature Research Station, has been appointed superintendent of the Station.

DR. GEOFFREY GEE has been appointed director of research of the British Rubber Producers' Research Association in succession to Mr. J. Wilson.

DR. H. CULLUMBINE has been appointed professor of physiology in the University of Ceylon, which came into existence in 1942 by the incorporation of the Ceylon University College (founded in 1921) and the Ceylon Medical College (founded in 1870). During the War, Dr. Cullumbine was engaged in research in the Physiology Department of the Chemical Defence Experimental Station, Porton, and since then he has worked in the Department of Pharmacology, University of Manchester.

THE fourth Mercer Lecture of the Society of Dyers and Colourists will be delivered on May 2 at the Royal Technical College, Glasgow, by Mr. E. J. Bowen, of University College, Oxford, who will speak on "Colour and Constitution: Absorption of Light by Chemical Compounds".

THE annual malaria control courses for planters, miners and others are to be resumed at the London School of Hygiene and Tropical Medicine. This year the course will be held at the School during June 23–27. The course is free. Applications to attend should be sent as early as possible to the Organising Secretary, Ross Institute of Tropical Hygiene, Keppel Street, Gower Street, London, W.C.1.

THE Trustees of the Ramsay Memorial Fellowships for chemical research will consider at the end of June applications for one fellowship of value £300 per annum, tenable for two years. Particulars can be obtained from the joint honorary secretaries, Ramsay Memorial Fellowships Trust, University College, London (Gower Street), W.C.1, to whom applications must be forwarded not later than May 31.

THE suggested summer school in X-ray crystallography at Manchester (see *Nature*, March 22, p. 398) will be held during September 1–12. Applications to attend must be received not later than May 12.

ERRATUM. In *Nature* of March 22, p. 387, review of "The Milky Way": the longest axis of the Galaxy is more than 100 thousand light-years, not 100 million light-years as printed.

Neutron Experiments of the Physical Laboratory of Groningen

In the beginning of 1940, a few months before the occupation of Holland by the Germans, we started some neutron experiments in this Laboratory (see ref. 1). To determine neutron energies the well-known boron absorption method was applied. Following Frisch's example[2], boron was used not as a compound but in the pure amorphous state. This boron arrived in March 1940 in Groningen from the British Drug Houses, Ltd. As it yielded nearly the same results as a sample of amorphous boron from Merck (Germany) which we had still in the laboratory, we had not the slightest suspicion that our results could be spoiled by too high an amount of impurities.

That this was really the case could be anticipated as soon as the new results for the resonance energies of silver and other elements, which had been found by the time of flight method, had been published[3,4,5].

Prof. Wiebenga, who kindly made an analysis of the boron we used in our neutron absorption experiments, found an impurity content of not less than 39 per cent. From this it might be concluded that the resonance energies hitherto published from our laboratory should be multiplied by $(0{\cdot}61)^2 = 0{\cdot}37$. As has been shown by the authors cited above, however, the neutrons suppressed by cadmium have in the mean an energy of 0·041 eV. instead of being really thermal neutrons, as was generally assumed hitherto. We used Rasetti's value of $\sigma_B = 4{\cdot}7\ E^{-1/2}$ cm.^{2}/gm.[6], whereas the mean of the values found by the authors quoted in refs. 3, 4 and 5 is $6{\cdot}4\ E^{-1/2}$ cm.^{2}/gm. We therefore conclude that our resonance energies should be multiplied by a factor $1{\cdot}85 \times 0{\cdot}37 = 0{\cdot}69$ to reduce them to their scale. This gives for the resonance energy of silver $0{\cdot}69 \times 8{\cdot}2 = 5{\cdot}7$ eV., in excellent agreement with their results (5·8 and 5·1 respectively).

In a paper soon to be published in *Physica* we shall deal in more detail with the other numerical data of our papers. Here it may be remarked that the general conclusions we arrived at remain valid, since the same correction has to be applied to all resonance energies.

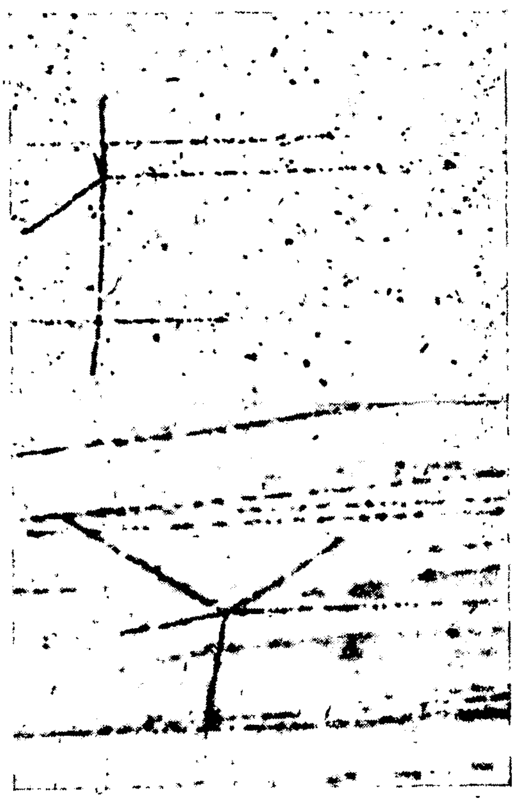
Disintegration of Nitrogen into Four α-Particles by Collision with Deuterons

We have recently exposed photographic plates, coated with the Ilford 'Nuclear Research' emulsions, to the 9 MeV. deuteron beam delivered by the Liverpool cyclotron. The deuterons were allowed to pass into the surface of the emulsion at a small angle of glancing incidence, and an exposure of less than 0·01 sec. was found to be sufficient to give a convenient number of tracks per unit area of the emulsion. In making measurements of the lengths of the tracks of the deuterons, we found, in addition to numerous forked tracks due to collision of deuterons with protons, examples of disintegrations produced by the entry of primary particles into nuclei of light elements, such as carbon, oxygen and nitrogen, present in the emulsion.



Two examples of a particularly interesting type of disintegration are shown in the accompanying photomicrograph. In the top photograph it will be seen that three deuterons have entered the emulsion, and that one of them has reacted with a nucleus and caused the emission of four particles. The lower photograph shows a similar event. The grain spacing in the tracks of the secondary particles is characteristic of α-particles and, since nitrogen is present in the gelatine, we attribute the disintegration to the reaction

$$N_7^{14} + H_1^2 \rightarrow 4\,He_4^2.$$

The possibility of this reaction was first mentioned by Cockcroft and Lewis[1], who observed a continuous distribution of α-particles from nitrogen bombarded with deuterons; but they could not establish the fact of its occurrence in their experimental conditions.

We have now observed five events of this type, and the correctness of our interpretation can be proved by applying the principles of the conservation of mass-energy and of momentum. The lengths and spatial orientations of the tracks were determined, by the usual methods employed in the photographic technique, and the energy and momentum of the corresponding particles deduced from the range-energy curve for the emulsion. The units of momenta are calculated according to the formula $M = \sqrt{2mE}$, where E is the energy in MeV., and m the mass number of the nucleus.

For each particular disintegration we define a system of rectangular co-ordinates OX, OY, OZ, in which the origin O is taken to be the centre of disintegration and OX coincides with the direction of motion of the incident deuteron. The spatial orientations of the tracks enable us to determine the values of the momenta M_x, M_y, M_z, of the individual α-particles. In those cases in which all the particles end in the emulsion, the results show that the sum of the components M_y and M_z of the four α-particles produced in each particular disintegration differs from zero by amounts less than the probable error, while the sum of the components M_x is equal to the momentum of the deuteron, M_d. In some cases one of the particles leaves the emulsion, and its momentum, and hence its energy, has then been determined by applying the relations $\Sigma M_y = 0$, $\Sigma M_z = 0$. The results of measurements on three of the disintegrations are given in the table.

No.	ΣM_x	M_d	ΣE_α (MeV.)	E_d (MeV.)	Q (MeV.)
1	5·61	5·75	14·20	8·29	5·91
2	5·49	5·69	14·33	9·10	6·23
3	5·80	5·52	13·19	7·58	5·61

The difference between the sum of energies of the α-particles, ΣE_α, and the energy of deuterons, E_d, gives us the Q value for the reaction. The mean value, $Q = 5 \cdot 92$ MeV., differs from that calculated from the masses only by 0·40 MeV.

The successful application made in the present experiment serves to emphasize the important contribution which the photographic method has to offer in the detailed study of nuclear disintegrations. Apart from the Wilson cloud chamber, which is very slow, this is the only method in which all particles resulting in the disintegration can be recorded simultaneously. This, therefore, permits the application of the principle of the conservation of momentum in addition to that of conservation of energy. The scope of the method, for experiments of this type, is clearly very great.

Elementary Photochemical Process in Halides of Bivalent Metals

IN 1929, Hilsch and Pohl[1] discovered an elementary photochemical process in the crystals of halides of *monovalent* metals, owing to a lucky choice of substances and to the application of an extremely subtle method. The assumption of the transition of the electron from the halogen ion to the ion of the metal in the halide crystals of monovalent metals was described first by Fajans[2] and also by Sheppard and Trivelli[3].

A similar elementary process takes place in the absorption of light in aqueous and alcohol solutions of alkali-halogen salts, as was stated by Franck and Scheibe[4] and confirmed by Butkow[5].

So early as 1937, one of us compared the long-wave edges of the spectra of calcium chloride, magnesium chloride and magnesium bromide crystals[6] with the spectra of the vapours[7] of these salts and directed attention to the fact that the shift of the long-wave edges of the first bands in the transition from the crystal to the vapour, as well as the corresponding shifts of the absorption bands of cæsium chloride, bromide and iodide, coincide (approximately) with the sublimation heats of the corresponding salts.

Proceeding from this fact, the hypothesis was set forth[8] that the elementary photochemical process taking place in the halide crystals of *bivalent* metals consists in the transition of an electron from the halogen ion X^- to the ion of the bivalent metal M^{++} with the formation of the subhalide (M^+X^-).

In order to check this hypothesis, consider the following cyclic process:

$$\begin{tikzcd}
{[M^{++}X_2^-]} \arrow[r, "{[h\nu]^{gr}_{\text{theor}}}"] \arrow[d, "Q^0_{MX_2}"'] & {[M^+X^-]X} \arrow[r, "Ad^0_X"] & {[M^+X^-] + (X)_0} \arrow[d, "Q^0_{MX}"] \\
{[M] + [X_2]} \arrow[rr, "\frac{1}{2}S^0_M + \frac{1}{2}D^0_{X_2}"'] & & {[M] + \frac{1}{2}[X_2] + (X)}
\end{tikzcd}$$

where $[h\nu]^{gr}_{\text{theor}}$ denotes the quantum of radiant energy corresponding to the long-wave edge of the first absorption band of the MX_2 crystal; $Q^0_{MX_2}$ and Q^0_{MX}, the reaction heats of the formation of MX_2 and MX respectively at the temperature of absolute zero; S^0_X and $D^0_{X_2}$ have the usual Born–Haber cycle meaning Ad_X, adsorption energy of the halogen atoms X in the crystalline lattice of the subhalide $[M^+X^-]$.

From the cyclic process we have:

$$[h\nu]^{gr}_{\text{theor}} = Q^0_{MX_2} - Q^0_{MX} + \tfrac{1}{2}S^0_{X_2} + \tfrac{1}{2}D^0_{X_2} - Ad^0_X \quad (1$$

The comparison of the experimentally determined first absorption bands of MX_2 crystals with the long wave edges of these bands, calculated theoretically from equation 1, is given in the accompanying table and in Fig. 1, and has justified the above hypothesis with respect to *highly polar* compounds, MX_2.

Fig. 2 gives a schematical representation of the absorption spectra of crystals of the *weakly polar* compounds CdX_2 and ZnI_2.

With the help of equation 1, we have calculated the values of the energies $[h\nu]^{gr}_{\text{theor}}$ also for the weakly polar compounds, which correspond to the formation of a non-excited halogen atom (these values of th energy in Fig. 2 are represented by a vertica arrow, ↑).

We have calculated also the energy which corresponds to the transition of the electron from the

MX_2	$Q^0_{MX_2}$ [9]	$1/2\ S^0_{X_2}$	$1/2\ D^0_{X_2}$ [10]	Q^0_{MX} [11]	Ad^0_X	Long-wave edge		Position of maximum
						$[h\nu]^{gr}_{theor}$	$[h\nu]^{gr}_{exp}$	$[h\nu]^{max}_{exp}$ [12]
$BaCl_2$	8·97	—	1·27	2·65	0·05	7·54	6·9	7·7
$CaCl_2$	8·36	—	1·27	2·26	0·05	7·35	7·0	8·1
$MgCl_2$	6·62	—	1·27	0·78	0·05	7·06	7·05	7·6
$BaBr_2$	7·89	0·18	0·98	2·43	0·05	6·57	5·9	7·3
$MgBr_2$	5·33	0·18	0·98	0·43	0·05	6·01	6·0	6·5

(All values are in e-volts)

halogen ion to the ion of the metal, with the formation of an *excited* halogen atom:

$$[h\nu^*]^{gr}_{theor} = [h\nu]^{gr}_{theor} + A_X,$$

where A_X denotes the *excitation* energy of the halogen atom[13]. The values of the energy $[h\nu^*]^{gr}_{theor}$ in Fig. 2 are represented by circles, O.

A consideration of Fig. 2 leads one to the conclusion that the first absorption bands in weakly polar MX_2 crystals are connected with the transition of the electron from the halogen ion to the metallic ion with the formation of an excited halogen atom. It should be noted that in the absorption of light by weakly polar MX_2 molecules in the vapour state, the halogen atom is split off from the MX_2 molecule also in the excited state[14]; this is not so in the case of halides of bivalent lead, cobalt and nickel[15].

The absorption of light by the weakly polar MX_2 halides both in the gaseous and the crystalline state is thus accompanied by the formation of excited halogen atoms, which we believe to be connected with the fact that cadmium chloride, bromide and iodide and zinc iodide are characterized by *layer* crystal lattices, representing a type of lattice intermediate between the co-ordination and molecular types.

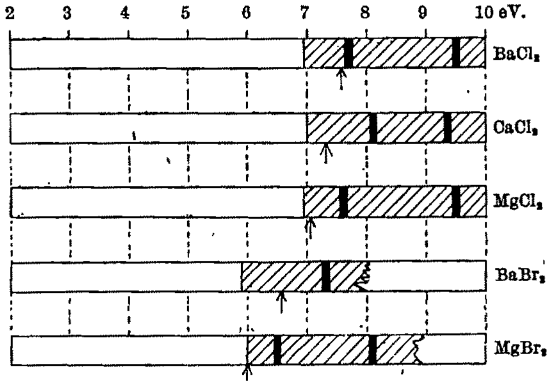

Fig. 1. Thick black line, maximum of absorption; hatched area, long-wave edge of spectrum; ↑, calculated value of $[h\nu]^{gr}_{theor}$

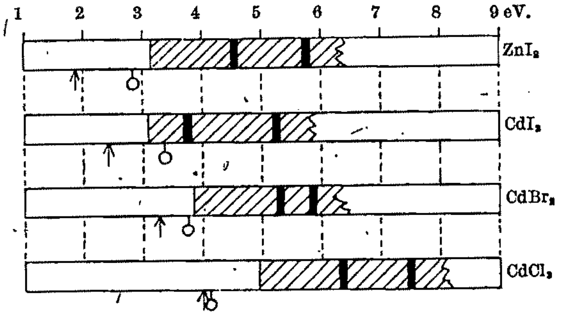

Fig. 2. Thick black line, maximum of absorption; hatched area, long-wave edge of spectrum; † and O, calculated values of $[h\nu]^{gr}_{theor}$ and $[h\nu^*]^{gr}_{theor}$

In the case of highly polar MX_2 compounds (M = Ba, Ca, Mg), the first absorption band, both in the crystalline and the gaseous phase, is connected with the formation of non-excited halogen atoms.

Finally, intermediate cases are possible; for example, thallium chloride and bromide, in which, in the crystalline state (lattice of the CsCl type), the absorption of light leads apparently to the formation of non-excited halogen atom, while in the gas phase the molecule is photodissociated[16] with the formation of excited halogen atoms. This is due to the fact that, owing to the high ionization potential of the thallium atom, the polarizing action of Tl^+, according to Fajans' general theory of ionic polarization, is so large that the molecules of thallium chloride, bromide and iodide in the gaseous state are atomic (and not ionic).

Oxidation Activity of Selenium Dioxide

In a recently published review on the mechanisms of oxidation, W. A. Waters[1] states that scarcely any evidence can be adduced for the mode of action of selenium dioxide. Since the discovery[2] of its specific oxidative activity, the interactions of selenium dioxide with more than three hundred organic compounds[3] of the most diverse character have been investigated: a common stoichiometric mechanism could scarcely be expected. There is, however, evidence which suggests the direction in which we should look for an explanation.

Many of the reactions have one feature in common, namely, the oxidation products are highly reactive substances; they must, therefore, have been formed initially in a low-energy state, otherwise they would certainly have suffered further oxidative degradation. Spectrographic investigations[4] have shown that in the luminous, high-temperature oxidation of organic gases and vapours and of ammonia in selenium dioxide vapour, none of the electronic energy-levels in the product molecules is excited; the radiation emitted consists of diffuse bands and a continuous region in the visible (5620–4600 A.), with no trace of radiation in the ultra-violet. These bands are probably due to selenium or possibly SeO molecules. The phenomenon indicates that when the activated reaction complex breaks down, the greater part of the energy of the reaction and the activation energy remains with the selenium. It is not improbable that similar phenomena occur in the condensed phase at somewhat lower temperatures, where visible radiation would not be expected.

The unique oxidative reactivity of selenium dioxide probably depends upon this electronic property of the selenium. The structural characteristics of the organic molecule undergoing oxidation will govern the formation of the necessary unstable intermediate compound or activated complex.

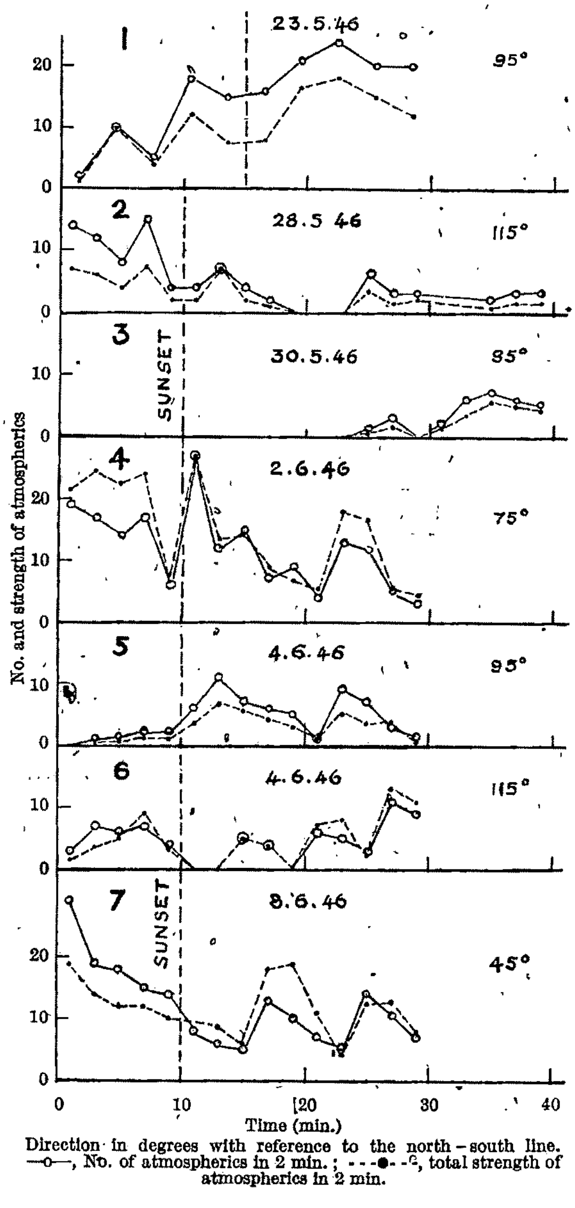
Location of Thunderstorm Centres from Directional Observations of Atmospherics During Sunrise and Sunset

IT has been known for many years[1] that there are anomalies in the number and strength of the *distant* atmospherics observed during the sunrise and the sunset periods. Investigations[2] in this laboratory on distant atmospherics on high and medium radio frequencies showed unmistakable maxima during sunrise and sunset. Previously, Potter[3] had observed similar effects. The effect of sunset on atmospherics was also reported by Subba Rao[4]. Besides Potter and Namba[5], Khastgir[6] recently offered an explanation of the sunrise and sunset effects observed. The object of the present communication is to show that on this theory a simple method can be devised for the location of a thunderstorm centre which gives rise to atmospherics by observing the time of occurrence of the maximum in the strength of the atmospherics, when the distant thunderstorm prevails over a period of time covering sunrise or sunset. The results of some directional observations of atmospherics at about sunset are also given in this connexion.

From a distant thunderstorm centre in the troposphere, the atmospheric pulse of waves is usually reflected from the ionosphere and reaches the receiving point. In the small hours of the morning, it is evident, the intensity of the down-coming waves, originally coming from the distant source of atmospherics, increases gradually with the slowly decreasing ionization in the *E*-layer until, on the incidence of the solar rays, at sunrise, there is a great increase in the ionization, causing a large fall in the intensity owing to greater absorption in the layer and also to greater deviation of the rays due to higher electron concentration. This causes a maximum in the strength of the atmospherics about the time of sunrise. Before sunset, again, the intensity of the down-coming waves gradually increases, due to a continuous decrease in ionospheric absorption, until at the instant of the withdrawal of the solar rays at sunset the intensity suddenly falls. This is because when the ionizing solar rays are withdrawn there is a perceptible decrease in the *E*-layer ionization, and the down-coming waves are much less deviated and necessarily fail to reach the receiving point. This gives a maximum in the strength of the atmospherics about sunset time. Afterwards, however, the smaller ionospheric absorption asserts itself, causing at first a slow decrease of intensity and ultimately an increase.

The work on the early morning increase of *E*-layer ionization by Mitra and his co-workers[7] has shown that the ionization begins to increase, not when the early morning solar rays strike the *E*-layer by grazing the earth's surface, but when the rays strike the layer by grazing the surface of the ozonosphere at a height of 35 km. above the earth. The sun's rays, in order



Direction in degrees with reference to the north – south line. —o—, No. of atmospherics in 2 min.; - - -●- -○, total strength of atmospherics in 2 min.

to produce ionization in the E-layer, should, therefore, pass over the ozone region, so that radiations of the shorter wave-lengths will not be absorbed by the ozone. Keeping this conclusion in view, the time of occurrence of the increase of ionization in the E-layer by the sun's rays at dawn or of the decrease of ionization when the solar rays are withdrawn at dusk can be found with reference to the ground sunrise and sunset times. This would correspond to the time of occurrence of the maximum of atmospherics observed about the time of sunrise or sunset.

If the angle between the two tangents on either side of the ozonosphere from the point of ionospheric reflexion is denoted by $(180° - \varphi)$, it can be shown that the difference between the instant of ground sunrise or sunset and the time of occurrence of the atmospherics maximum is given by : $\Delta T = 4\varphi \pm (l_s - l_r)$, where l_s and l_r denote the longitudes of the source of atmospherics and the receiving point. The value of φ in the above relation can be calculated approximately from the known values of the heights of the E-layer and the ozone layer and from the location of the receiving point. If now the latitude λ_r and longitude l_r of the receiving point are known, the latitude λ_s and the longitude l_s of the source of atmospherics can be easily determined from the observed value of ΔT, remembering, however, that the observed angle of arrival of the atmospherics is given by $\tan\alpha = \dfrac{\lambda_s \sim \lambda_r}{l_s \sim l_r}$. Having thus obtained the location, the distance of the thunderstorm centre can be easily found.

A few typical experimental results on 1,000 metres on the subject are shown in the accompanying graphs. Here the number and total strength of the atmospherics (in arbitrary units) for 2 min. are plotted against time for specified directions. One distinct case of successive double reflexion simultaneously occurring with the usual single reflexion between the source of atmospherics and the receiving point is shown in curve No. 6, where there are three peaks at regular intervals. The location of the source of atmospherics in such cases is obtained with reference to the middle peak. It is likely that curves 5 and 7 represent two other similar cases, where possibly the farthest of the three successive peaks is not observed. The location and the distance of the thunderstorm centres for the cases illustrated are given in the accompanying table. The experiments were performed with the cathode-ray tube D.F. equipment of the Council of Scientific and Industrial Research (India), to whom our thanks are due.

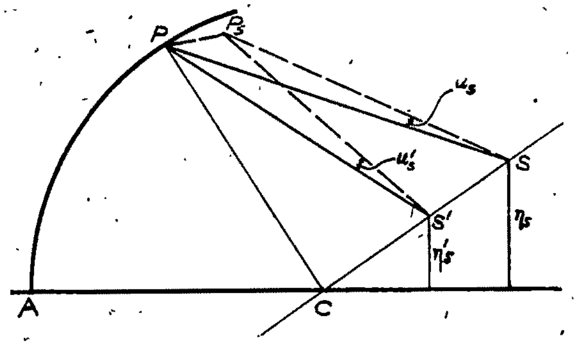
An Optical Magnification for Finite Objects

IF N, u, η are the refractive index, the paraxial angle, and the size of object respectively, and dashes denote these quantities in the image space, then the magnification formula,

$$m = \frac{\eta'}{\eta} = \frac{Nu}{N'u'}, \quad . \quad . \quad . \quad (1)$$

is valid for limiting by small values of η only, with the same condition applying to the invariance of the quantity $Nu\eta$ throughout the system. It is, however, possible to derive a similar expression which is valid for finite object sizes.



In the diagram, PS, PS' are incident and refracted principal rays, S, S' being the foci of close sagittal rays P_sS, P_sS'. It is known that S, S' lie on the auxiliary axis $CS'S$. Let the heights of S, S' be η_s, η_s'; these will be called sagittal objects and image heights. Then the magnification is

$$m = \frac{\eta_s'}{\eta_s} = \frac{CS'}{CS} = \frac{s' \sin I'}{s \sin I},$$

where $s = PS$, $s' = PS'$; $I = \angle SPC$, $I' = \angle S'PC$. If now the sagittal paraxial angles $u_s = \dfrac{PP_s}{s}$, $u_s' = \dfrac{PP_s}{s'}$ be introduced, one has

$$\frac{\eta_s'}{\eta_s} = \frac{Nu_s}{N'u_s'}.$$

Thus η_s', η_s are related by the sagittal magnification $m_s = \dfrac{Nu_s}{N'u_s'}$, and the quantity $Nu_s\eta_s$ is invariant irrespective of the magnitudes of η_s and η_s'.

It is also easy to prove the results by noting that the sagittal image heights describe object and image circles on rotation of the diagram about AC. The magnification of each element of the object circle so obtained is the same and equal to m_s. Thus the perimeters of the two circles being related by the sagittal magnification, so must their radii be similarly related.

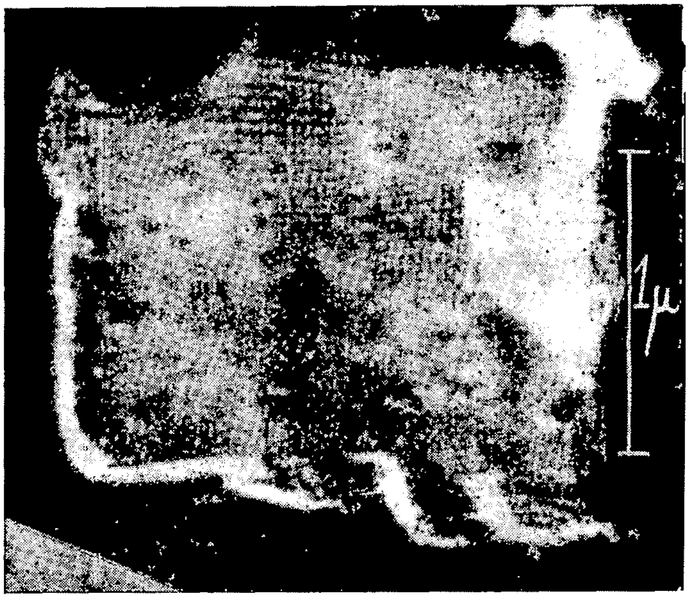
Electron Microscopy of Tobacco Necrosis Virus Crystals

Electron microscopy has shown the regular way in which the elementary particles, or molecules, of the southern bean mosaic virus are arranged in its crystals[1]. Not all crystallizable viruses are equally easy to examine in this fashion; but we have found that satisfactory photographs can be obtained of single crystals of a strain of the tobacco necrosis virus. They differ from the bean mosaic virus electron micrographs in a number of interesting and instructive ways.



Electron micrograph showing the particle arrangement over the face of a single tobacco necrosis virus crystal. × c. 38,000

The crystals were of microscopic size obtained from a purified solution of a newly isolated member of this group of viruses[2], prepared by high-speed centrifugation followed by salt precipitation. Replicas[3] of a dilute suspension of the crystals in half-saturated magnesium sulphate were made by spreading a small drop on a clean microscope slide, coating the dried spread with an obliquely evaporated gold film, reinforcing the gold with thin collodion and floating the combined film from the slide on to water for cutting and mounting on screens. The preparations in this form were given a final vertical deposit of a few angström units of beryllium to enhance their stability under the electron beam.

The molecular array over the face of a typical microcrystal of this necrosis virus can be seen in the accompanying reproduction. In the many fields examined, crystals have always been covered with a haze which probably is to be attributed to impurities remaining in the preparation. Though this interferes with photography at the highest magnifications, it does not obscure many features of the crystalline structure. The molecular net of nearly all the necrosis virus crystals that have been photographed suggest, as does the one shown here, a frayed piece of wire screening. The extensive irregularities of these nets have prevented very accurate determinations of interparticle distances. Nevertheless, measurements across 10–20 molecular rows in undisturbed regions indicate that the same particle separation, c. 275 A., prevails in both the vertical and the horizontal directions. In the bean mosaic crystals the separation is nearly 50 per cent greater in one direction than in the other. The rows of particles are approximately at right-angles, but the net is not strictly cubic. In the crystal illustrated here, its obtuse angle is c. 95°.

The photographs made thus far do not establish with certainty the way succeeding layers of particles overlie one another to build up a crystal. Most of the evidence points to the lattice being simple, though a body-centred arrangement cannot yet be excluded.

Many of the thinnest deposits probably were formed as the crystal suspension dried on the slide. Their particles, too, are in a square network. Regular arrangements having no more than a dozen or so particles on a side are also not uncommon. This ability of the necrosis virus to crystallize directly from solution should make it especially valuable for use in studies of the first steps in crystal formation.

The electron micrography of this virus is being continued; its results will be described in more detail elsewhere.

Alloxan Diabetes and the Kidney in the Rat

Jimenez-Diaz, Grande-Covian and De Oya[1] have reported recently that dogs in which the vessels of both kidneys were clamped prior to and for ten minutes following the intravenous injection of 100 mgm./kgm. of alloxan failed to develop either the hyperglycæmia or the uræmia of the controls in which the clamping was omitted. On the basis of this experiment they postulated the existence of some factor in the kidney with which the alloxan must come in contact before it can exert its full diabetogenic effect.

Alloxan is known to exert a specific toxic action on the beta cells of the islets in many species[2]. It was felt that should there be a chemical factor in the kidney necessary to mediate the toxic effect, it would be present in all those species in which the diabetogenic action was observed. We chose the rat to test the hypothesis.

Male and female adult hooded rats, of a strain bred in this laboratory, weighing between 175 and 250 gm., were fasted for twenty-four hours, then operated on under ether anæsthesia. In the control group the abdomen was opened, the inferior vena cava exposed, and injection of 100–175 mgm./kgm. alloxan in aqueous solution made into this vein. In the experimental group, the kidneys were exposed, the pedicles dissected free and the vessels clamped prior to the injection. The clamps were then left in place for ten minutes as described by Jimenez-Diaz and collaborators in their original report. Following this treatment the animals were returned to their cages and allowed food and water *ad lib.* Blood-sugar determinations were made on tail-vein blood samples obtained from the survivors at 24 and 48 hours following the injection. A condensation of the results is shown in the accompanying table; 48-hour blood sugars only are tabulated as the 24-hour and earlier samples were found to be erratic in both groups. Blood-sugar values greater than 130 mgm. per cent were listed as hyperglycæmic in this summary as the sugar method used (Somogyi and Nelson[3]) gives low values corresponding to true sugar. However, only two rats fell into the group with blood sugar 130–150 mgm. per cent; the remainder all displayed levels higher than 250 mgm. per cent. No differences were noted due to different treatment doses used, namely, 175, 150, 140 and 100 mgm./kgm., and all the results are included together in the table.

	Kidneys clamped		Kidneys not clamped	
	No. of rats	Per cent	No. of rats	Per cent
Total	36	100·0	18	100·0
Survivors at 48 hr.	22	61·1	12	66·7
Hyperglycæmic at 48 hr.	18	50·0 81·7*	11	61·1 91·6*

* Percentage of survivors.

Differences between the two groups were not found to be significant when tested with the fourfold table and Fisher's χ^2 method.

A further group of three rats was nephrectomized, following which 275 mgm./kgm. alloxan was injected intraperitoneally in aqueous solution. At 24 hours the animals were sacrificed, blood sugars determined and pancreases sectioned and stained. Typical necrotic changes, disappearance of granules, pyknosis, shrinkage of cytoplasm, were seen in the pancreases of all three animals, although the blood-sugar levels at the time of death were 58, 138 and 216.

A possible mechanism for the effects observed by Jimenez-Diaz and collaborators was suggested to me during the course of the above experiments. Goldner[2] has shown that if a portion of the pancreas is clamped off for as little as five minutes during and subsequent to the injection of alloxan in rabbits, the clamped portion fails to show histological signs of damage while the unclamped portion displays typical necrosis. During the dissection of the renal pedicle in some of the rats, a temporary blanching of the pancreas was observed. This was thought to be due to reflex vasoconstriction. If this same mechanism operates in the dog, only to a more marked degree, it might afford sufficient curtailment of pancreatic blood flow while the alloxan was being inactivated to protect the islets from the toxic action.

The Renal Factor in Alloxan Diabetes

JIMENEZ-DIAZ *et al.*[1] have recently reported their failure to induce diabetes in dogs by the intravenous injection of alloxan when both renal pedicles were clamped immediately before and for ten minutes after its administration. They concluded that "the contact between alloxan and the kidney is apparently necessary for the display of the full diabetogenic effect". We have repeated these experiments in rabbits and find that alloxan diabetes of the usual degrees of severity is produced when the kidneys are excluded from the circulation by clamping of the renal pedicles.

In our experiments, white domestic rabbits varying in weight from 1·9 to 2·9 kgm. were used. In each case, alloxan in a 5 per cent aqueous solution was administered intravenously in a single dose of 200 mgm. per kgm. of body-weight. Control and experimental animals were always grouped together and injected with the same freshly prepared solution of alloxan. Preliminary study established the fasting blood-sugar level for each animal. Before and for 48 hours after the injection of alloxan, the animals were allowed food *ad lib.*, and non-fasting blood-sugar levels were determined at intervals beginning at 2 hours and thereafter at 4, 8, 12, 16, 20, 24 and 48 hours after the administration of alloxan. Determinations of the fasting blood-sugar levels were made at 72 and 96 hours.

Eight of the fourteen rabbits employed in this experiment were normal control animals treated with alloxan. Six of these eight rabbits became diabetic and two were resistant to the diabetogenic action of alloxan. The blood-sugar content of the diabetic animals varied from 360 to 640 mgm. per cent. Two of the animals that became diabetic had been injected with alloxan while anæsthetized with nembutal and ether. A ninth animal was subjected to similar anæsthesia and, in addition, to the operative procedure of bilateral renal pedicle clamping for 12 minutes with clamps that were known by previous experience to produce complete obstruction of renal blood flow as proved by the absence of bleeding when the renal pedicle was transected. No alloxan was administered to this animal. The blood-sugar returned to a normal level within 8 hours after this operative interference, and remained so thereafter. The remaining five animals were subjected to an identical operation under the same general anæsthesia and, when both renal pedicles were clamped, alloxan was administered. The clamps were allowed to occlude renal blood flow for ten minutes after the end of the injection of alloxan, and then were removed with the re-establishment of renal circulation. Three of the five animals thus treated became diabetic as judged by the fasting blood-sugar level after 96 hours, these levels being 352, 420 and 520 mgm. per cent respectively. It was noted that both control and experimental animals exhibited the usual variability and irregularity of blood-sugar content during the 24-hour period immediately following the administration of alloxan.

In order to test further the existence of the diabetic state, glucose tolerance tests were done several days before and 72 or 96 hours after the injection of alloxan. The test dose consisted of 1·5 gm. of hydrated glucose per kgm. of body-weight, given intravenously in the fasting state as a 20 per cent aqueous solution. The fasting blood-sugar levels at 72 and 96 hours, together with the results of the glucose tolerance tests, demonstrated that all animals that had received alloxan, whether apparently resistant to its action or not, showed a more or less marked impairment of glucose metabolism. This observation was further confirmed by the detection of an alimentary glycosuria in the alloxan-treated animals that had normal fasting blood-sugar levels, and this in turn was found to occur during periods of abnormal postprandial hyperglycæmia.

Some of the animals died or were killed on the fourth or fifth day of the experiment, but the blood-sugar levels of those that survived were followed for varying periods up to four weeks. While in general the level of the blood sugar at 72 and 96 hours was a reliable index of the subsequent course, nevertheless, in one rabbit treated with alloxan alone, and in two subjected to clamping of the renal pedicle and to alloxan injection, there was a gradual reduction of the fasting blood sugar to normal levels. On the other hand, one rabbit that appeared to be non-diabetic 96 hours after clamping of the renal pedicle and alloxan injection became markedly diabetic on the twelfth post-operative day, and was killed on the sixteenth day when the blood-sugar level was 495 mgm. per cent. In our previous experience with alloxan diabetes in the rabbit, we have encountered such anomalies not infrequently.

In histological sections of the pancreas of animals given alloxan while the renal pedicles were clamped, there was found evidence of recent necrosis of the beta cells of the islets of Langerhans indistinguishable from that seen in control animals treated with alloxan alone. Moreover, identical necrosis of the islets of Langerhans was observed in two rabbits injected with the same intravenous dose of alloxan as the animals described above, but immediately after bilateral nephrectomy.

It is obvious that our observations in the rabbit are distinctly at variance with those of Jimenez-Diaz *et al.* in dogs. While the preliminary data that we have presented are quite inadequate to demonstrate that exclusion of the kidney from the circulation has no effect whatever upon the development and course of alloxan diabetes, nevertheless our observations demonstrate clearly that it is possible to produce in the rabbit necrosis of the islets of Langerhans and the development of a typical diabetic state by the intravenous injection of alloxan while the renal circulation is arrested by clamping of the renal blood vessels. We conclude, therefore, that the continuance of renal circulation during, and for a short time after, the injection of alloxan is not essential to the diabetogenic action of alloxan in the rabbit.

It is a pleasure to acknowledge that this investigation was assisted by grants-in-aid from the Cooper Fund of the Faculty of Medicine, McGill University, and from the National Research Council, Canada.

Practical Three-Hour and Two-Hour Cylinder-Plate Assays for Penicillin

IN the course of experiments designed to stu
cytochemical changes which occur in susceptib
cells under the influence of penicillin, we appli
various stains and reagents to agar plates prepar
as for the standard *FDA* cylinder-plate assa
which is essentially similar to that recommended
Schmidt and Moyer[1]. The technical procedures e
ployed and the cytochemical observations are bei
reported in detail elsewhere, and are interpreted
terms of an equilibrium between sulphhydryl a
disulphide groups[2]. It will suffice here to state th
thresholds for a number of chemical groupings we
shown to exist at the boundaries of zones of inhibiti
on plates seeded with *Staph. aureus NRRL.* stra
No. 313, or with the rough form of *B. subtilis NRR*
strain No. *B*-558, and afterwards exposed to penicilli
It is well known that these test organisms are mo
sensitive to penicillin when they are in the logarithm
phase of growth. Therefore, we found it advantageo
to pre-incubate the seeded plates for three hou
before adding the solutions to be tested[3]. When th
is done, a secondary incubation period of three hou
for *Staph. aureus* or of two hours for *B. subtilis*
sufficient for the minute colonies developed duri
primary incubation to react to the diffusion of pe
cillin so that the thresholds can be located clearly
suitable techniques.

All the techniques which we have used th
sharply delineate the zones of inhibition agree
locating the threshold at the same distance (with
the limits of experimental error) around a cylind
from which a given concentration of penicillin h
been permitted to diffuse for a given length of tim
Therefore, any of these procedures can be applied
practical tools for completing assays of penicill
within two or three hours from the time the unknow
solution is placed on test. A rapid technique, involvi
impregnation of the plates with silver and subseque
physical development, has been shown to give ass
values that agree closely with those obtained by t
longer standard method, requiring sixteen hours
incubation and diffusion[3]. Therefore, plates process

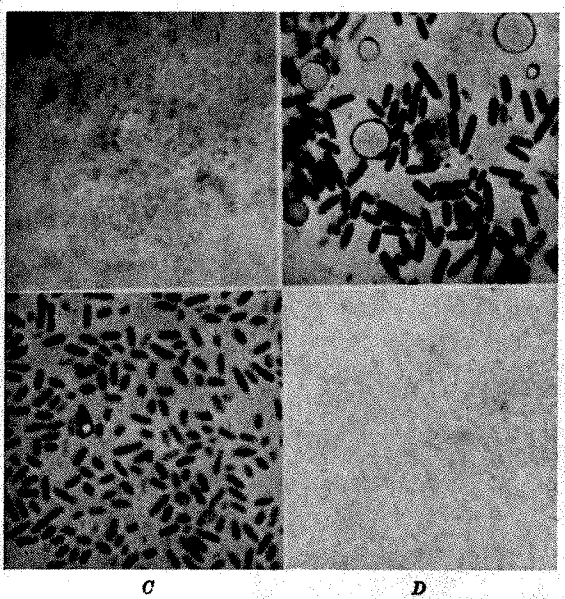
Nucleotide Metabolism of Bacteria and the Bacterial Nucleus

OWING to the content of purine and pyrimidine ings of the nucleic acids, they exhibit a specific bsorption within the ultra-violet range with an bsorption maximum at 2600 A. This makes it ossible to demonstrate directly the presence of ucleotides in cells. The quantitative conditions can e studied by means of the technique devised by Caspersson and co-workers. A method has now been vorked out in which the order of magnitude of the ucleotide content in bacteria can be determined by hotometry of microphotographs taken at 2570 A.

Both Gram-negative and Gram-positive bacteria ave been investigated (*Escherichia coli, Aerobacter erogenes, Proteus vulgaris, Flavobacterium, Bacillus ereus, Staphylococcus albus, Streptococcus fœcalis, Spirillum rubrum* and *Corynebacterium diphtheriæ*), nd a series of investigations was carried out for ach type of bacterium; about forty organisms vere used.

In all cases great changes took place in the nucleotide content during the early phase of growth, the ucleotide content reaching a maximum during the nd of the lag phase or the beginning of the logarithmic hase. The nucleotides of the individual bacterium nderwent an increase corresponding to five to ten imes the original content. A general conception of he variations is obtained from the accompanying eproduction, which shows the content of absorbing ubstance in *E. coli* on four different occasions. The ontrast obtained in the positive is a relative measure f the nucleotide concentration.



PHOTOGRAPHS OF *E. coli* TAKEN AT 2570 A. *A*, INOCULUM; *B*, MIDDLE OF LAG PHASE; *C*, BEGINNING OF LOGARITHMIC PHASE; *D*, PHASE OF DECLINATION

In the case of *E. coli*, where a nitrogen analysis was made in one experiment, it was found that, on the whole, the total amount of nucleic acid and protein followed the same course. Further, it appears that there was a connexion between the length of the generation time and the nucleotide metabolism. The amount of nucleic acid newly formed during the generation was in inverse relation to the generation time. However, this did not hold good for the first generation, during which the new formation was especially pronounced. The divergence for this generation and the lag phase included in it may be interpreted as an expression of a diffusion or a secretion of protein, the formation of which has been shown to presuppose the presence of nucleotides (Caspersson).

The increase in nucleotides and in the volume of the individual bacterium occurred during the same period. The volume variations were especially pronounced for *B. proteus*, in which the increase in volume and nucleotide content ran parallel and were in inverse relation to the size of the inoculum. The increase in size could be ascribed mainly to an uptake of water.

The observations made by ultra-violet microspectrography and Feulgen–Rossenbeck's nuclear reaction indicated that the bacteria have two nucleotide systems connected with bacterial growth, one of ribose and the other of ribodesose type. In common with a number of other research workers, we were able to prove the presence of Feulgen-positive structures which evidently undergo fission in connexion with bacterial fission. The formation of ribose nucleotides appears to start from ultra-violet-absorbing grains, which in connexion with the intense increase of nucleotide disappeared in the diffusely absorbing bacteria. We consider that we have gained support for the assumption that bacteria have a nuclear mechanism the function of which agrees in principle with that met with in metazoan cells. The two systems form a functional unit, but are not combined in a morphological unit. The ribodesose organella which undergoes fission would form an equivalent to the euchromatin of the metazoan cell; the ribose system would be looked upon as a functional counterpart to the heterochromatin. From the former the formation of gene protein is induced; the latter controls the formation of the protein of the cell body. This latter process is reflected in great changes in the content of ribose nucleotides in the individual bacterium.

A detailed account of this work will be published shortly.

Cytochemical Effects of Œstradiol

The œstrogenic action of certain carcinogenic hydrocarbons such as 3:4 benzpyrene and 5:6 cyclopentane-1:2 benzanthracene and the carcinogenic effect of œstrogenic hormones (see recent review by Greenstein[1]) suggested to us a comparison of the cytochemical effects of œstradiol on the vaginal wall of mice with the primary effects of methylcholanthrene on the epidermis studied in detail by Cowdry and his collaborators.

As early as 24 hours after the injection of 10 mgm. œstradiol into a mouse, ovariectomized one month previously, the proliferating vaginal wall shows a very marked increase in alkaline phosphatase activity, especially in the cytoplasm of the cells (technique of Gomöri[2]). This observation was confirmed by *in vitro* determinations of phosphatase activity in vaginal extracts, which show that orthophosphate liberated in three hours from sodium glycerophosphate increases, for example, from 430 γ to 1,500 γ P per mgm. protein nitrogen. This increase in alkaline phosphatase activity is accompanied by a large increase in cytoplasmic ribonucleic acid detected by the ribonuclease technique of Brachet and confirmed by estimations following Schneider's technique[3].

These two phenomena are comparable to those which have been found to occur in mouse epidermis after methylcholanthrene treatment (Biesele[4]).

An increase in alkaline phosphatase activity of the same order of magnitude is shown in the uterus, principally in the circular muscle layer[5]. In this organ, also, there is a parallel increase in the concentration of ribonucleic acid. One can observe regularly a slight increase in alkaline phosphatase activity in the liver, but no increase in brain, kidney or blood plasma.

Brachet and Jeener[6] have put forward the hypothesis that the increase in phosphatase activity observed in the nuclei of regenerating liver may be related to the increase in thymonucleic acid phosphorus turnover. A similar hypothesis does not seem to be applicable to variation in cytoplasmic phosphatase activity. For example, the ribonucleic acid metabolism in pancreas must be very high (Caspersson[7]), notwithstanding the fact that phosphatase content of this organ is very low.

On the other hand, the data given in this report are in agreement with the idea that an increase in alkaline phosphatase is not parallel to general protein synthesis, but only to the synthesis of fibrous proteins (see review by Moog[8]). Keratin is rapidly synthesized by the vaginal wall under the influence of œstradiol. Some preliminary data lead us to believe that myosin synthesis occurs in the uterus unde the same conditions. The absence of any increase o phosphatase activity in the crop of the prolactin-injected pigeon can well be explained by the absence of any histological signs of keratin or collagen fibre synthesis during the growth of its mucosa. Finally, we note the similarity between effects of œstradiol on vaginal and uterine phosphatase and those o androgen hormones on the prostate (Gutman[9]).

Synthesis of Methionine and Similar Amino-Acids

Of several recent syntheses of *dl*-methionine, tha commencing with γ-butyrolactone[1] is relatively long while others[2] are additionally inconvenient in tha they employ methyl-β-chloroethylsulphide, a vesican intermediate. It seems, therefore, desirable to stat that the following series of reactions has been foun to afford an overall yield of *dl*-methionine of 29 pe cent (that is, based on acrolein), and to be free fro disadvantages such as those mentioned above:

$$CH_2:CH.CHO \xrightarrow{MeSH} CH_2(SMe).CH_2.CHO \xrightarrow{HCN}$$

$$CH_2(SMe).CH_2.CH(OH)CN \xrightarrow{NH_3/EtOH}$$

$$CH_2(SMe).CH_2.CH(NH_2)CN \xrightarrow[\text{at } 100^\circ]{\text{Conc. HCl}} dl\text{-methionine}$$

Commercial acrolein containing a trace of tri ethylamine was treated with methylthiol to giv β-methylthiopropionaldehyde, which, after isolation, was allowed to react with liquid hydrogen cyanide in presence of a small amount of potassium cyanide. The crude cyanohydrin was converted at 80° into the corresponding aminonitrile, which was isolated as its oxalate and hydrolysed to methionine. It may be recalled that β-methylthiopropionaldehyde has previously been obtained from acrolein[3], though apparently only under obscure conditions or in small yield. Moreover, the methylthioaldehyde has been converted by what are in principle the steps outlined above into *dl*-methionine[4], but low yields seem to have given the premature impression that this synthesis is of little practical value.

In the present work similar reactions have also been used to prepare analogous acids such as ethionine, α-amino-γ-benzylthio-*n*-valeric acid, and α-amino-γ-benzylthio-γ-methyl-*n*-valeric acid in satisfactory yield. The last-mentioned compound has been debenzylated to give α-amino-γ-thio-1-γ-methyl-*n*-valeric acid, an analogue of penicillamine, the degradation product of the various penicillins.

A full account of these syntheses has been submitted for publication in the *Journal of the Chemical Society*.

Origin of Erythrocytes

It seems desirable to utter a caveat in reference o Dr. S. H. Wajda's communication on the origin of erythrocytes from striated muscle[1]. During he last two years, many hundreds of sections of muscles previously traumatized by various means have been studied in great detail in this Department. In view of the suggestion often made in he past (and particularly in view of the recent work of Chèvremont) special search has been made for convincing evidence of the transformation f muscle fibres into various types of connective tissue cells. Unfortunately, the histological picture is usually extremely confused in the traumatized rea at first and, unless the sections are studied with critical eye, it is possible to mistake histiocytic and ther phagocytic elements for actual transitional forms between disintegrating muscle cells and various connective tissue cells. Because of these difficulties, it has been reluctantly concluded that this type of material is really not adequate for the solution of such a problem. In some cases it can be ertainly demonstrated that the appearance seen under the microscope suggesting a transformation of a muscle fibre into histiocytes is quite illusory although, of course, this does not preclude such a possibility).

It seems not improbable that the suggested transformation of striated muscle fibres into red blood corpuscles (a process which is referred to by Dr. Wajda as 'instantaneous') is also based on such illusory appearances. One of the members of this Department has been engaged for several months in the study of living striated muscle fibres by micro-dissection, and has often watched them *in vivo* for several hours after traumatization. In no case has any process been observed which is even remotely similar to that described by Dr. Wajda.

W. E. Le Gros Clark

Department of Human Anatomy,
Oxford.

[1] *Nature*, **159**, 254 (1947).

The working hypothesis on blood formation on which Prof. Le Gros Clark comments was put forward because the wealth of observation behind it could not fit any established views on hæmopoiesis, and because some general statement was warranted, if for no other reason, as a basis for further experiment. My views are based both on extensive cytological observation and on experimental evidence which will be fully discussed elsewhere.

I do not agree that the histological picture of traumatized muscle is so confused as to defy critical examination. The architecture of striated muscle is much more regular than that of loose connective tissue, a tissue of choice in the study of inflammation, and a cytologist should not encounter any great difficulty in following its cellular changes.

Judging from his own published work on muscle, Prof. Le Gros Clark's studies have been neither concerned with muscles working at the time of fixation, nor with acute changes in them, nor, indeed, with blood formation. This might, in part, account for his failure to confirm my observations. At the same time, I might direct attention to the fact that there is a photomicrograph (Fig. 23) in his latest paper which clearly shows cells budding off from an injured muscle fibre, and the process itself is described in some detail in the text. Prof. Le Gros Clark decided, however, that the fate of these new elements could not be determined.

It is necessary for me to emphasize again that the instantaneous discoidal disintegration of muscle fibres had been described long before I was able to confirm its occurrence. It has also been recently observed *in vivo*, and recorded cine-photomicrographically by Speidel as a "progressive transformation of single sarcomeres into discrete thin clots". As Speidel points out: "a few seconds of electrical stimulation were sufficient to initiate the formation of an incipient clot". It should not, therefore, be impossible to check Thoma's statement that disintegration may begin "plötzlich in beinahe explosionsartiger Weise" by repeating both his and Speidel's experiments.

Internal Waves and Upwelling of Oceanic Water from Mid-depths on to a Continental Shelf

In January 1947 at a time when the winter maximum for inorganic phosphate dissolved in the sea is usually reached, a series of observations was made in the western English Channel. In an area north of the coast of Brittany in water of $35{\cdot}40$–$35{\cdot}45\,{}^0/_{00}$ salinity, temperature about 1° C. higher than in the surrounding water and a zooplankton community typical of 'south-western' water[1], phosphate around $0{\cdot}40$ mgm.-atom/m.^{3} P was found. If, as appears probable, this is typical of Atlantic surface water at midwinter, the 'Channel' (setosa)[1] water, characterized by the presence of the chætognath, *Sagitta setosa*, which has occupied the English Channel in the neighbourhood of Plymouth since 1930–31 and has similar maximum phosphate content (0·42–0·48 mgm.-atom/m.^{3} P), may well have been derived from it. We should, however, have to look elsewhere for the origin of the higher phosphate content (0·6–0·7 mgm.-atom) of the 'elegans' or 'western' water[1] of the Celtic Sea, which in the nineteen twenties also filled the western end of the English Channel. The most probable source is upwelling of deeper ocean water from the continental slope. Such upwelling may be attributed to off-shore winds, which would need to be from the north and east. South-westerlies are the prevailing winds of the area both in direction and strength, and the winds from the northern and eastern sectors would, in general, seem not to blow hard enough or long enough to produce upwelling on the scale required. Periods of prolonged fresh easterly winds such as February 1947 are rather exceptional.

There is another possible mechanism by which nutrients could be brought from the deeper waters on to the continental shelf. The existence of internal or boundary waves in the ocean with an amplitude up to 100 metres is now well established. If such waves should impinge at right angles to a vertical cliff, no doubt they would be totally reflected. The continental slope, though steep, is far from vertical, so that the energy of an impinging wave must be dissipated in some other way. Most probably such a wave would run up the slope much as a surface wave runs up a shelving beach. In this way nutrient-richer water at mid-depths could be brought higher on to the shelf, where normal vertical mixing due to wind-waves and surface winter cooling would complete the process of bringing the richer water to the surface.

No evidence has yet been adduced to show whether or not submarine valleys or canyons such as those found on the New England coast are present along the continental slope west of the English Channel. If such exist, they would concentrate the energy of the internal wave into a contracting cross-section and greatly amplify the power of an internal wave to project deeper water into the surface layers. For a full understanding of the fertility of the sea in this area, a synoptic survey of the internal waves in the Atlantic abreast of the slope and a knowledge of the topography of the slope itself is therefore called for.

Relative Directions of the Electric and Magnetic Vectors in Electromagnetic Waves *in vacuo*

Are the electric vector ($\vec{E}$) and the magnetic vector ($\vec{B}$) in electromagnetic waves *in vacuo* always mutually perpendicular, or are they not always so?

I put this question to a number of distinguished physicists, and all of them, without exception, answered definitely in the affirmative at first—and then agreed with me that the correct answer should be in the negative.

It follows from the Maxwell equations

$$\dot{\vec{E}} = c \operatorname{curl} \vec{B} \qquad \dot{\vec{B}} = -c \operatorname{curl} \vec{E}$$

that the time derivative vector of $\vec{E}$—not the vector itself—is perpendicular to $\vec{B}$ and, correspondingly, the time derivative vector of $\vec{B}$—not the vector itself—is perpendicular to $\vec{E}$. But the directions of the vector and of its time derivative always coincide only in the case of a non-rotating vector. This is, however, as a rule, not so in the case of a rotating vector (take, for example, the acceleration and the velocity in curvilinear motion).

Thus, in plane polarized plane electromagnetic waves, where the vectors $\vec{E}$ and $\vec{B}$ do not rotate, they are mutually perpendicular; but in rotating electromagnetic waves[1] and in electromagnetic whirls[2], where these vectors rotate, they are, generally speaking, *not* mutually perpendicular. Only in some exceptional cases are $\vec{E}$ and $\vec{B}$ perpendicular, in spite of rotation. This happens, for example, in circularly polarized plane waves, where both vectors are coplanar and rotate with equal angular velocity always at right angles to each other; and in spherical or in cylindrical waves, where one of the vectors rotates in an axial plane, while the other vector remains in the same position in an angular plane[1,2,3].

Apparently this point is usually overlooked, because until quite recently very little attention was given to the study of electromagnetic waves with rotating vectors other than plane and spherical waves

Origin of Solar 'Static'

Recently, Martyn[1] wrote: "It is natural first to seek an explanation [of the origin of solar static] in terms of the kind of electrical discharge which cause the familiar terrestrial radio noise, namely, lightning flashes; but it is difficult, if not impossible, to se how such discharges could be produced in the alway highly ionized solar envelope". The explanation to which Martyn raises objection is, in fact, one which I have myself put forward recently[2]. His objection however, does not arise on the general theory which I have advanced elsewhere[3]. Far from preventing the existence of electric fields at the sun's surface the thermal conditions there are themselves the result of electrical discharges. These discharges occur i the radial electric field set up by the emission o highly charged atoms from nuclear reactions in th sun's interior.

CHEMISTRY OF THE PROTEINS

A DISCUSSION meeting on the "Chemistry of the Proteins" was held by the Chemical Society in the University of Bristol on February 13. Prof. J. L. Simonsen was in the chair, in the absence, through illness, of the president, Prof. C. N. Hinshelwood. The following papers were submitted: (1) "The Integration of Physical Methods in the Elucidation of Protein Structure", by Prof. J. D. Bernal; (2) "Modern Methods of Amino-Acid Analysis", by Dr. G. R. Tristram; (3) "The Degradation of Proteins by Proteolytic Enzymes", by Dr. J. A. V. Butler; (4) "Some Physico-Chemical Aspects of Plasma Proteins", by Dr. R. A. Kekwick.

Prof. Bernal outlined the physical methods by which information on the size, shape and crystal structure of the intact protein may be obtained. The ultra-centrifuge, with which Svedberg made the first great advance in the investigation of the gross structure of proteins, has now been shown to have certain fundamental limitations. As a method of estimating absolute molecular weights, it has probably an accuracy of 20 per cent, but it still provides accurate comparative data in investigations involving the fractionation of proteins. The electrophoresis technique introduced by Tisélius is also of great value in comparative studies, but it can do no more than separate out the different groups of proteins. Information on the shape of the protein particle has been obtained by sedimentation, viscosity and anomalous viscosity measurements and flow birefringence.

In reviewing the whole field Prof. Bernal stated that X-rays provide the most accurate means of investigating the gross architecture of the protein crystals. Perutz and Crowfoot have demonstrated how X-ray technique may best be applied, and their work has provided much information on the crystal structure of hæmoglobin and insulin respectively. The usefulness of the technique would be extended when it became possible to carry out measurements on the protein crystal in solution.

The electron microscope is a new instrument, now in the process of development; its resolving power is now about 10 A., and in the near future a resolving power of 5 A. may be expected. Already many remarkable results have been obtained, and the instrument may prove to be one of the most powerful means of examining the structure of proteins.

In conclusion, Prof. Bernal suggested that the time has now come when the efforts of the various branches of protein research should be co-ordinated.

Dr. G. R. Tristram next outlined the means which are now available for the investigation of the amino-acid composition of proteins. Prior to 1939, most of the methods were gravimetric, required upwards of 10 gm. of protein for each analysis and yielded results upon which little reliance could be placed. In recent years, there has been a rapid development of methods, based upon many novel principles, which require very small amounts (10–100 mgm.) of protein. Among the more important of these methods are: electrodialysis for the estimation of the basic amino-acids; partition chromatography for the estimation of certain of the mono-amino-acids; specific decarboxylases; isotope dilution and microbiological assay. Microbiological assay, which has undergone tremendous development in the United States, and isotope dilution are capable of application to the whole range of amino-acids, although it is impossible to assess their real value because much of the work on the microbiological technique has been uncritical, and so far isotope dilution has not been widely used.

The assessment of the accuracy of any method of analysis is handicapped by the impossibility of carrying out *bona fide* control experiments. It is therefore suggested that each method should (i) be capable of giving reproducible recoveries when tested on *ad hoc* mixtures of amino-acids; (ii) that the values obtained should be reproducible; and (iii) should be capable of duplication by independent methods.

A special technique has recently been developed by Sanger which makes it possible to characterize and estimate the amino-acids which provide the terminal NH_2 group(s) of the inact protein. Using this technique, much interesting information has been obtained by Sanger and his co-workers.

Insulin has now been analysed by Chibnall and his co-workers, and their chemical data suggest that the 'submolecule' has a molecular weight of about 12,000 and contains about 106 residues (102 of which have been characterized by analysis). The work of Sanger reveals that each 'submolecule' has four chains, the terminal amino-groups of which are two residues each of glycine and phenylalanine.

The development and uses of paper chromatography were outlined by Dr. A. H. Gordon. This qualitative technique makes possible the micro-detection and characterization of amino-acids and peptides. It has been used by Martin and Synge and their co-workers in their work on the structure of gramicidin-S.

Dr. J. A. V. Butler suggested that another method of approach to the determination of protein structure is by partial enzymatic hydrolysis. The products of hydrolysis should have molecular weights of about 1,000. Experiments have been carried out on the action of chymotrypsin and pepsin on insulin. The initial action of chymotrypsin is to hydrolyse off about eight peptide fractions, molecular weight *c.* 700, leaving a fairly massive core having a mean molecular weight of about 5,000. The latter is still precipitable by trichloracetic acid and is therefore easily separated. It contains the greater part of the cystine. Pepsin, on the other hand, breaks the molecule into fragments having a mean molecular weight of about 3,000.

It was observed many years ago that when peptic digests of insulin and other proteins are concentrated and treated with more pepsin at *p*H4, substances, insoluble in trichloracetic acid, the so-called 'plasteins', are formed. This was thought to be due to a resynthesis of peptide bonds. It has now been found that insoluble material is formed when peptic digests are incubated at various hydrogen ion concentrations, even when pepsin has been inactivated. It is suggested that some of the original peptic fragments still retain much of the order of the original protein and, when heated and treated in other ways, undergo changes similar to those which occur in protein denaturation, giving rise to an insoluble product.

Dr. R. A. Kekwick outlined methods of protein preparation with special reference to the plasma proteins. Although it is possible to isolate proteins by electrophoresis, the amounts obtained are necessarily limited. The method is of great value, however, for the control of fractionation procedures.

The solubility of a protein in aqueous solution depends upon pH, salt concentration, temperature and total protein concentration. Cohn studied the fractionation of plasma proteins with ethanol and established that, provided the temperature is maintained between 0° and $-10°$ C., a further variable, the reduction of protein solubility by means of solvents, may be introduced with great advantage.

In the past, the application of electrophoresis and the ultra-centrifuge have been the main criteria for the purity of protein preparations. As Prof. Bernal pointed out, these methods are not adequate for the assessment of absolute purity. It is now generally agreed that the final test for purity of any protein should be the estimation of solubility, that is, the solubility should be independent of the amount of protein present in the solid phase.

THE MATHEMATICAL ASSOCIATION

ANNUAL MEETING

A GENERAL meeting of the Mathematical Association was held at the Polytechnic, Regent Street, W.1, during April 9 and 10, under the presidency of Mr. W. F. Bushell, head-master of Birkenhead School.

Mr. Bushell covered a wide field in his presidential address, "A Century of School Mathematics", giving a comprehensive and detailed account of the changes which have revolutionized the teaching of school mathematics in England during this period. The general level of mathematical teaching in mid-Victorian times was described by means of much instructive and entertaining material drawn from the two famous inquiries commonly known as the Clarendon Commission and the Endowed Schools Commission. By 1871, the sterility of a dull routine of a little arithmetic, algebra and Euclid, with no attempt to relate these topics to everyday life, was generally recognized by teachers; but the Association for the Reform of Geometrical Teaching (now the Mathematical Association), founded by Levett (King Edward School, Birmingham) and J. M. Wilson (then of Rugby, later head-master of Clifton and canon of Worcester), struggled for many years with the inertia of the older universities, the influence of which on the school curriculum through examinations was preponderating. The work of the Association did not begin to show real fruit until the early years of the present century; but since then, steady progress has been made towards an understanding of the proper place of mathematics in the schools and towards a mode of teaching which shall recognize the dual aspect of mathematics, as a high exercise in abstract thinking, and as a basic human element in the life of the ordinary citizen. Mr. Bushell noted that turning-points in the teaching of mathematics had occurred simultaneously with wars and crises in world affairs, the foundation of the Association for the Reform of Geometrical Teaching in 1871, the Balfour Act of 1903, and the Fisher Act of 1917; and he drew from this the hope that the Butler Act of 1944 would afford teachers of mathematics an opportunity for still further reforming progress.

During the afternoon of April 9, a demonstration and discussion on "The Place of Visual Aids in the Teaching of Mathematics" was held. Mr. I. R. Vesselo showed a number of films and film strips, suggesting possible uses for such visual aids in ordinary class teaching, and Mr. G. Patrick Meredith described a general theory of 'graphics' underlying the use of such material. The discussion seemed to show that the majority of teachers are not convinced that the film material as yet available in mathematics is sufficiently helpful to allow it to replace blackboard and chalk. In connexion with the discussion, Mr. Vesselo had arranged a very comprehensive exhibition of visual aids, which was open during the two days of the meeting. Models, wall charts, pictures, diagrams, all bearing on the teaching of school mathematics, had been collected in large numbers, and showed how much can be done with simple and inexpensive materials.

Later, Prof. H. Davenport (University College, London) gave a paper on "The Geometry of Numbers", in which he described in extremely lucid and simple fashion the way in which Diophantine problems in the theory of numbers can be solved by the application of geometrical concepts, a method due in the first place to Minkowski, and since then used and developed by many workers in this field.

The proceedings on April 10 opened with a paper from Mr. B. C. Brookes (Bedford) on "The Incorporation of Statistics into a School Course". The general opinion of teachers is in favour of such incorporation; but there are difficulties which have often proved insuperable, due, for example, to the influence of external examinations on the school curriculum. Mr. Brookes dealt with the place of statistics in a 'sixth form' curriculum and also in the general mathematical course in a school, and paid attention to the necessary detail of content, method and balance between theory and application. Members were much impressed by the sound practical suggestions put forward in this paper.

Dr. R. L. Goodstein (University of Reading) spoke on "Proof by *reductio ad absurdum*". He analysed the formal logic underlying such proofs, showing how they depend essentially on the logical 'law of contradiction' and 'law of the excluded middle', and by means of an example exhibited the difficulties and paradoxes which may arise. Again, by means of three simple examples he showed that a direct proof may often be not only as simple as an indirect proof, but may in general be expected to yield more precise information. He referred briefly to recent work on logic by Post and Lukasiewicz, in which many-valued logica systems are elaborated; in such systems the two values 'true' and 'false' of a proposition are replaced by three or more.

A discussion took place on April 10 on "A Unified Course in Mathematics in Secondary Schools", being in some sense a sequel to last year's discussion on mathematics in the 'modern' school. The discussion was opened by Mr. A. W. Riley (Wolverhampton), Mr. K. S. Snell (Harrow) and Miss E. Barnes (Birmingham). All three of the opening speakers stressed the need for seeing the school course in mathematics from the point of view of the child, rather than considering it as a mental discipline imposed on the child from above. All agreed that in the early stages the child's knowledge must grow out of his (or her own needs and increasing awareness of the externa world. For this purpose, mathematics should b presented not as a set of disconnected water-tight compartments labelled 'arithmetic', 'algebra', etc. but as a growing body of knowledge which will b rithmetical, algebraical, geometrical or trigonometrical in turn as occasion demands. The growth f such knowledge was compared to that of a tree, vith a main trunk from which in due time various ranches will spring, not all at the same time, nor ll growing at the same rate. Mr. Riley discussed he whole field, and made specific suggestions for the etails of a unified course ; Mr. Snell dealt with the arlier part of the secondary course, and Miss Barnes vith the later part, referring specially to her own vork in a girls' school. In the open discussion, Mr. . V. Durell stressed the importance of equipping the hild with the mathematical tools which he will need or life in the modern world, and the equal importance f training the child to select the mathematical tool ppropriate to a particular task. The discussion was igorous and keen ; the need for suitable text-books vas mentioned, but many members agreed with Mr. R. L. Parsons (Merchant Taylors') in his insistence hat if a clear objective is, first and foremost, envisaged by the child, and then by the teacher, the ext-book problem is but a small matter.

The final paper of the meeting was by Mr. P. F. Burns, on "Astronomy in the Schools". Mr. Burns poke as an enthusiast, but he wasted no time on bstract arguments ; he went straight to the point y showing how much can be done with children hose mathematical knowledge is very small. On he minimum—a surprisingly small one—of such nowledge, he showed how children in two schools n the same meridian, one in Lancashire and one in loucestershire, had made and combined observations o as to be able to deduce the length of the circumference of the earth. By ingenious cutting and olding of simple diagrams, with a little elementary eometrical drawing, he showed a method for determining the great circle distance between two points n the earth's surface.

The president of the Association for the forthcoming year is Prof. G. B. Jeffery, principal of the nstitute of Education, University of London.

THE BEGINNING OR THE END? "

THE much-heralded film "The Beginning or the End ?" (Metro-Goldwyn-Mayer) was shown privately to a distinguished audience in the Palace heatre, London, on April 22. Judged by any andard or from any point of view, it is not a good m. Generally, it is dull—a cardinal sin in a film eant for the commercial cinema. From the documentary point of view it is disappointing, since it ally tells so little about all the atomic research hich led eventually to the release of atomic energy ; fact, it confines itself solely to that comparatively hort time devoted to the development of the atomic omb in the United States. This will assuredly lead he non-scientists into believing that most atomic nergy research has been American. Apart from three ss well-known British atomic scientists who, according to the film, represented the British contribution dered to America by Mr. Winston Churchill, the haracters are all American. (It is stated that Fermi orked in his native Italy until 1939.)

Towards the beginning of the film, lip-service was aid to the contributions of such geniuses as Rutherford, Joliot, Chadwick, Hahn and a few others, in ne or two sentences uttered from his arm-chair by n actor representing Einstein, but whose elocution as so poor that even this small concession will be lost on a lay audience. Meitner, Oliphant, Blackett, Cockcroft, Bohr and other important persons were not mentioned at all. On the other hand, Oppenheimer, Fermi, Vannevar Bush, Urey, Conant, Szilard, Compton and Lawrence were all represented in the plot, though, with the exception of Fermi and Szilard, none figured very largely.

It is true that the film confined itself to the development of the atomic bomb, and we know that most of that work took place in the United States. In view of this, it would have been better if the entire film had been produced as a documentary. But if the world is to realize the importance of atomic energy research and its effect for good or ill on man and his future it would have been best not to lift this section of an almost world-wide and long-drawn-out team work from its context. A more faithful, comprehensive and revealing study of the science of the atom is necessary if the commercial cinema is to continue its excellent contributions to adult education, to which we have frequently referred. Perhaps in due course, Metro-Goldwyn-Mayer or the J. Arthur Rank Organisation will consider presenting to the public the whole romance of atomic research, going back even as far as Dalton and reaching as a climax not only the release of atomic energy in the form of a bomb but also a few prophetic shots of what atomic energy could do for power production, medical research, etc. Then we may be sure that such scientific worthies as Thomson, Curie and Rutherford will be revealed as important contributors to what is really one project.

A 'brains trust' followed the showing of the film—not to discuss and criticize the film but to answer questions of human interest in connexion with atomic energy. Its personnel comprised Royal Air Force and Royal Navy observers at the actual bomb explosions, two politicians, an actor and author and Dr. C. E. M. Joad. It will be noted that science itself was not represented on this 'trust' in spite of the fact that the omission was pointed out to the organisers in plenty of time for it to be rectified. This is to be deplored, especially in view of the fact that several atomic physicists of international fame are within comparatively easy reach. It is to be hoped that we may not look upon this choice as indicative of the attitude of the intelligent public to present-day science.

One important function this film might have is to bring home to every man and woman who sees it a deeper sense of urgency which seems to be lacking, especially in Britain. A copy of the film was buried with due solemnity beneath the giant redwoods of California, to be disinterred five hundred years hence. If anyone exists then, we doubt whether he will learn anything that he has not already learned from more authoritative sources, especially the publications of the men of science themselves.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, April 28

CHEMICAL SOCIETY (in the Chemistry Lecture Theatre, King's College, Newcastle-upon-Tyne), at 5 p.m.—Scientific Papers.

INSTITUTION OF POST OFFICE ELECTRICAL ENGINEERS (at Faraday Building, 9th Floor, South Block, Knightrider Street, London, E.C.4), at 5 p.m.—Mr. K. W. Hix : "Repeater Station Power Supplies".

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Discussion on "Domestic Water Heating by Electricity" (to be opened by Mr. R. Grierson and Mr. Forbes Jackson).

INSTITUTION OF THE RUBBER INDUSTRY, MANCHESTER SECTION (at the Engineers' Club, Albert Square, Manchester).—Annual General Meeting.

Tuesday, April 29

University College (at Gower Street, London, W.C.2), at 5.15 p.m.—Dr. M. H. Pirenne: "The Quantum Physics of Vision" (other lectures on May 6 and 13).*

Royal Anthropological Institute (at 21 Bedford Square, London, W.C.1), at 5.30 p.m.—Prof. F. E. Zeuner: "Climate and Early Man in East Africa".

Royal Photographic Society, Scientific and Technical Group (at 16 Princes Gate, London, S.W.7), at 7 p.m.—Dr. E. E. Loening: "The Latent Image in the Test Tube".

Sheffield Metallurgical Association (at 198 West Street, Sheffield), at 7 p.m.—Mr. Brinley Jones: "Springs for High Duty Purposes".

Society of Instrument Technology (at the Royal Society of Tropical Medicine and Hygiene, Manson House, 26 Portland Place, London, W.1), at 7 p.m.—Mr. J. A. Hall: "Molten Metal Temperature Measurement".

Wednesday, April 30

Botanical Society and Exchange Club of the British Isles (at the Linnean Society, Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Annual General Meeting.

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 5 p.m.—Mr. E. J. B. Lloyd: "Economic Reconstruction, 7, Distribution".

Challenger Society (at the Zoological Society, Regent's Park, London, N.W.8), at 5.45 p.m.—Dr. Anton Fr. Bruun: "The *Atlantide* Expedition to the West African Coast".

Institute of Welding (joint meeting with the Institute of Metals, at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 6 p.m.—Dr. Maurice Cook and Mr. Edwin Davis: "The Welding of Copper and the Copper-Rich Alloys".

Thursday, May 1

Institution of Mechanical Engineers, Graduates' Section (at Storey's Gate, St. James's Park, London, S.W.1), at 6.30 p.m.—Annual General Meeting. Mr. E. A. Ritchie: "Statistical Quality Control".

Chemical Society (at Burlington House, Piccadilly, London, W.1), at 7.30 p.m.—Scientific Papers.

Friday, May 2

Chemical Society, Exeter Branch (in the Washington Singer Laboratories, The University, Bristol), at 4.30 p.m.—Prof. M. Stacey: "Advances in Immunochemistry".

Society of Public Analysts and other Analytical Chemists, Physical Methods Group (in the Chemistry Lecture Theatre, King's College, Newcastle-upon-Tyne), at 6 p.m.—Papers on "Physical Methods of Gas Analysis".

Society of Dyers and Colourists (at the Royal Technical College, Glasgow), at 7.30 p.m.—Mr. E. J. Bowen, F.R.S.: "Colour and Constitution—Absorption of Light by Chemical Compounds" (Fourth Mercer Lecture).*

Saturday, May 3

British Interplanetary Society (at St. Martin's Technical School, Charing Cross Road, London, W.C.2), at 6 p.m.—Mr. M. W. Ovenden: "The Nature and Distribution of Meteors".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Graduate Assistant Teacher of Mechanical Engineering Subjects—The Principal, Twickenham Technical College, Egerton Road, Twickenham, Middx. (May 3).

Teacher of Mechanical Engineering Subjects—The Principal, Acton Technical College, High Street, Acton, London, W.3 (May 3).

Lecturer in the Department of Chemistry and Applied Chemistry—The Principal, Royal Technical College, Peel Park, Salford 5 (May 3).

Teacher of Mechanical Engineering Subjects—The Principal, Hendon Technical College, The Burroughs, Hendon, London, N.W.4 (May 3).

Lecturer in Mathematics—The Clerk to the Governors, Woolwich Polytechnic, Woolwich, London, S.E.18 (May 3).

Assistant Lecturer (well-qualified graduate) to teach Mechanical Engineering up to Higher National Certificate standard, and an Assistant Lecturer to teach General Mechanical Engineering to at least the Ordinary National Certificate, in the York Technical College—The Chief Education Officer, Education Offices, 5 St. Leonard's, York (May 3).

Director of Physical Research in the Admiralty—The Secretary, Civil Service Commission, 6 Burlington Gardens, London, W.1 quoting No. 1853 (May 8).

Scientific Assistant (temporary) in the Department of Zoology for research on fertility in mammals—The Secretary and Registrar, University College of North Wales, Bangor (May 8).

Lecturer in Geophysics—The Professor of Physics, Imperial College of Science and Technology, South Kensington, London, S.W.7 (May 10).

Research Officer (Fuel Chemist), Division of Aeronautics, Melbourne—The Secretary, Australian Scientific Research Liaison Office, Australia House, Strand, London, W.C.2, quoting No. 967 (May 12).

Senior Research Officer or Research Officer (male), Timber Mechanics Section, Division of Forest Products, Melbourne—The Secretary, Australian Scientific Liaison Office, Australia House, Strand, London, W.C.2, quoting No. 999 (May 12).

Research Officer (Theoretical Physics), Division of Industria Chemistry, Melbourne—The Secretary, Australian Scientific Liaison Office, Australia House, Strand, London, W.C.2, quoting No. 1004 (May 12).

Lecturer in Physics (up to B.Sc. Special standard), preferabl with subsidiary mathematics and chemistry, a Senior Assistant in Biochemistry or Biology, a Responsible Lecturer in Mechanica Engineering (up to Final B.Sc. standard), a Lecturer in Mechanical Engineering, and a Senior Assistant in Civil Engineering—The Registrar, Nottingham Technical College, Shakespear Street, Nottingham (May 12).

Senior Research Officer (X-Ray Crystallography), in th Division of Industrial Chemistry, Melbourne—The Secretary Australian Scientific Liaison Office, Australia House, Strand, London W.C.2, quoting No. 1229 (May 12).

Research Officer (Wood Chemistry Section), Division of Fores Products, Melbourne—The Secretary, Australian Scientific Liaiso Office, Australia House, Strand, London, W.C.2, quoting No. 123 (May 12).

Chair of Mining, and the Chair of Industrial Relations—Th Registrar, University College, Cathays Park, Cardiff (May 15).

Principal Scientific Officer at the Telecommunications Researc Establishment of the Ministry of Supply at Malvern, Worcs.—Th Secretary, Civil Service Commission, 6 Burlington Gardens, London W.1, quoting No. 1856 (May 15).

Superintendent (Projects and Planning) at the Royal Aircra Establishment of the Ministry of Supply—The Secretary, Civil Servic Commission, 6 Burlington Gardens, London, W.1, quoting No. 185 (May 15).

Lecturers (2) in Physics—The Registrar, The University, Glasgo (May 15).

Nuffield Fellowships (3) for experimental and theoretica research in Nuclear Physics, and Technical Assistants (2) in researc work in Atomic Physics—The Professor of Natural Philosophy, Th University, Glasgow (May 15).

Assistant Lecturer or Lecturer, and a Lecturer or Senio Lecturer, in the Department of Biochemistry—The Registra The University, Sheffield (May 17).

Assistant Keeper (Class II)—The Keeper and Secretary, Londo Museum, St. James's, London, S.W.1 (May 17).

Lecturer or Assistant Lecturer in Civil Engineering, and Lecturer or Assistant Lecturer in Geology—The Secretar King's College, Strand, London, W.C.2 (May 17).

Assistant Lecturer (Grade III) in Psychology, and an Assistan Lecturer (Grade III) in Chemistry—The Secretary and Registra The University, Bristol (May 19).

Lecturer in Physiology—The Registrar, The University, Leeds (May 19).

Assistant Lecturers (2, Grade III) in Mathematics, and a Assistant Lecturer (Grade III) in Chemistry—The Secretary an Registrar, The University, Bristol (May 19).

Readership in Agricultural Economics tenable at the Londo School of Economics and Political Science—The Academic Registra University of London, Senate House, London, W.C.1 (May 22).

Senior Principal Scientific Officer (to take charge of researc and other work on precise engineering measurements) at the Nation Physical Laboratory—The Secretary, Civil Service Commissio 6 Burlington Gardens, London, W.1, quoting No. 1859 (May 22).

Principal Scientific Officer (to take charge of a team of worke on the application of X-ray diffraction, etc., to the study of metal an other crystalline substances) at the National Physical Laboratory-The Secretary, Civil Service Commission, 6 Burlington Garden London, W.1, quoting No. 1860 (May 22).

Chief of the Division of Wool Technology, Geelong, Victo —The Secretary, Australian Scientific Research Liaison Office, Austra House, Strand, London, W.C.2 (May 24).

Lecturer or Senior Lecturer in Electro-Technics—T Registrar, The University, Manchester 13 (May 24).

Chair of Psychology—The Registrar, The University, Sheffie (May 24).

Research Officers (2), Division of Industrial Chemist Melbourne—(*a*, Reference No. 1253), to investigate bacterial car hydrate metabolism in relation to industrial fermentation processe (*b*, Reference No. 1254), to conduct investigations on proteins and t products of their hydrolysis by enzymes—The Secretary, Australi Scientific Research Liaison Office, Australia House, Strand, Lond W.C.2, quoting the appropriate Reference No. (May 26).

Assistant Government Chemist in Hongkong—The Director Recruitment, Colonial Service, 15 Victoria Street, London, S.W (May 26).

Lecturer in Botany (excluding physiology and mycology) in t United College—The Secretary, The University, St. Andre (May 30).

Senior Assistant in the Department of Civil and Mechanic Engineering, a Senior Assistant in the Department of Che istry, and a Lecturer in Chemistry—The Principal, Techni College, Queen Street South, Huddersfield.

Lecturer in Physiology and Zoology—The Registrar, Techni College, Sunderland.

Rector of, and Lectureships in, the Teacher Training Colle Achimota, Gold Coast—The Secretary, Achimota Committee, Ed burgh House, 2 Eaton Gate, London, S.W.1.

Senior Assistant Lecturer in the Department of Mechanic Engineering—The Principal, Borough Polytechnic, Borough Ro London, S.E.1.

Senior Lecturer (Senior Assistant) in Physics—The Princip Sir John Cass Technical Institute, Jewry Street, London, E.C.3.

Head of the Physics Department—The Clerk, Northern Po technic, Holloway, London, N.7.

Senior Chemistry Master (to take Chemistry up to scholars standard)—Headmaster, Loretto School, Musselburgh, Edinburgh

Lecturers (2) in Physiology—The Dean of the Medical Colle St. Bartholomew's Hospital, West Smithfield, London, E.C.1.

Laboratory Assistant with experience of food and/or biochemi analysis—Prof. Robertson, Royal (Dick) Veterinary College, Ed burgh 9.

DEVELOPMENT OF COLONIAL TERRITORIES

THE many-sidedness and complexity of research in the overseas territories of Great Britain are well illustrated in the five annual reports recently published under the title "Colonial Research", a digest of which appears on p. 614 of this issue; but fears that such research is over-organised or centralized excessively should be dispelled by the whole tenor of these reports. In the report of the Colonial Research Committee, in particular, it is observed that it, and the specialist committees in their particular fields, are not to be regarded as the sole fount and origin of all projects of research, and that it would be unfortunate if their mere existence were in any way to inhibit initiative on the part of other agencies or individuals who may have in mind projects of potential interest or value. On the contrary, the Committee would cordially welcome proposals from any source, and will be glad to consider recommending financial assistance toward their execution. As the Colonial Research Committee rightly points out, the scientific needs of the Colonies are too wide and too complex to be made the preserve of any single organisation of committees, and initiative and interest in these fields cannot be too widespread.

It is in keeping with this, and with the further fact that many of the problems, as these reports well illustrate, are regional in scope, that there is already a marked tendency towards collaboration across not merely Colonial but also national frontiers. Such collaboration is increasingly tending to take place at the technical and scientific level, and this may well prove an important factor in promoting closer political understanding and co-operation. Moreover, a second point made by the Colonial Research Committee in this, its third, annual report is of importance in the same connexion. In many fields the problems to be solved at the present stage themselves require accurate identification and definition before they can be profitably investigated. The Committee is therefore disposed to favour projects which have as their immediate objective the exploration and identification of problems, rather than intensive investigations.

Such background research, which enables the scientific problems of the Colonies to be seen in proportion, and general research plans to be framed with some confidence that emphasis is being placed in accordance with actual needs, is, in the Committee's view, required in much greater measure than in the past. Pilot surveys and preliminary studies of this type are in fact no less suitable for co-operation on a regional basis than those intensive investigations on well-defined problems where the value of international co-operation has been so effectively demonstrated during the last three decades.

While the other reports do not discuss the wider aspects of Colonial research in quite the same way or in general terms, such aspects are clearly being kept in mind, as is shown, for example, by the incidental comment of the Colonial Products Research Council that the promising work of evaluating the medicinal properties of many Colonial vegetable products would be gravely handicapped but for the ready co-operation of the Medical Research Council. Again, the general policy adopted by the Colonial Medical Research Committee of trying to obtain men with the initiative and originality necessary for good research, and encouraging them to choose their own problems and their own methods of approach, is well calculated to stimulate creative work of the standard most desired. The five reports, indeed, suggest that none of the Committees is unmindful of Rutherford's conviction that an academic atmosphere, with complete freedom to follow whatever paths of investigation seem desirable or necessary, is essential for progress in fundamental science.

Whether the Committees will be able to avoid, in present circumstances, what Rutherford regarded as such a grave mistake, namely, the tempting of men with high abilities for academic research into industrial or State laboratories, remains to be seen. Assuredly the most fruitful use of the available scientific man-power of Britain will tax the utmost wisdom of the administrator—be he man of science or layman—during the next decade, and the general attitude of these Research Committees as disclosed in these reports is reassuring. The matter is all the more important as the whole trend of Colonial developments, whether under the influence of the Trusteeship Council of the United Nations, or stimulated by such schemes as the plan for the production of ground-nuts in Tanganyika, Northern Rhodesia and Kenya resulting from an official mission to East Africa (Cmd. 7030. H.M. Stationery Office. February 1947. 1*s*. net), is likely to increase the demand both for research schemes and for scientific men in research and development work.

The high importance of this bold and comprehensive scheme for the development of backward territories must be stressed. Its potentialities for meeting the serious threat of famine which now faces East Africa, and to supply food, other than the fats primarily intended for the outside world, have attracted public attention to an extent which rather overshadows those aspects with which the scientific worker is more directly concerned. Even from the point of view of the difficulty which will be experienced in obtaining the staff and equipment required for success, it is important that the scheme should be carefully studied by men of science themselves. It is estimated, for example, that the permanent operation of the project will require about 750 Europeans, and this figure includes, in addition to unit managers and engineers, such specialists as surveyors, soil conservation experts, medical men and welfare superintendents as well as scientific staff. The project outlines a comprehensive research programme, both in regard to the use of land, and the human problems of nutrition.

The scheme is primarily intended to meet the critical shortage of oils and fats, amounting for Britain alone to an annual deficiency equivalent to one and a half million tons of ground-nuts; and although the present acute phase may have passed in four or five years, expert opinion predicts a continuing world shortage for the next ten to twenty years. The position can only be substantially improved by the most highly mechanized forms of agricultural development, and the scheme proposes to take a total area of 3,210,000 acres of waterless, almost uninhabited, fly-infested country, and convert it by mechanized units of 30,000 acres into a healthy farming region producing by 1950–51 a minimum of 600,000 tons of ground-nuts annually. Of the 107 units, eighty are proposed for Tanganyika Territory, seventeen for Northern Rhodesia and ten for Kenya. All the resources of modern scientific agriculture will be employed, and when the units have been brought into production, the farming operations will need a permanent labour force of 32,100 Africans, while at the peak of operations in 1949 and 1950, some 25,000 Africans will be required for bush-clearing alone.

This gigantic undertaking, with which the Government has already decided to proceed on the general lines recommended by the mission, is one of the most stirring examples of the contribution which science can make to human welfare. Apart from its importance in meeting the world's dietary needs of fats and the African need for subsistence, its economic and social effects are likely to be far-reaching. Local plans for development and welfare will be aided by the mass production of ground-nuts, particularly in regard to the clearing of tsetse-infested bush and the control of sleeping sickness, the establishment of water-supplies, the improvement of communications, and the provision of an economic foundation for social advance.

The latter aspect merits a little more detailed consideration. Reflecting the broader tendencies of modern thought, the project rules out private enterprise as permanent owners or operators. The United Africa Co., which is undertaking the initial work, will be replaced by a public corporation sponsored and financed by the British Government, but, with provision for the project to be taken over ultimately, first by the local Governments and eventually by the African communities themselves. Incidentally, the project paves the way for the eventual institution of the co-operative use of land, and it is this emphasis on the community rather than the transformation from primitive to scientific methods of cultivation that marks the truly revolutionary character of the scheme.

What has been lacking in most of the development and welfare schemes for the Colonial territories under the 1940 Act is evidence that development will proceed fast enough for the Colonies to carry their own burden of social services in the near future. Generally, the Colonies are being encouraged to plan for a higher standard of living before it is clear whether they will be able to maintain it. The danger is most apparent in the West Indies; but the present scheme, which involves a capital expenditure of about £24,000,000 spread over six years, well illustrates what is needed in order to raise standards of living.

The decision of the British Government to accept the financial risks of this scheme removes the main difficulty of securing the greater capital investment needed in the majority of development and welfare schemes, and while the scheme is as financially sound as expert foresight can make it, the reservation that agricultural development on the scale and of the type contemplated in the mission's report has not been attempted hitherto in tropical countries adds to, rather than subtracts from, the credit due to the Colonial Office for its initiative. Moreover, the scheme is only one of several measures taken by the Government. A public utility company has been formed to take over the whole of the electricity supply of Nigeria, and the Cameroons Development Corporation will cultivate 250,000 acres on a communal basis, growing rubber, bananas and oil-palms, while all mineral rights in the Colonies are to be nationalized.

This plan for East and Central Africa is thus an example of the kind of work which the Colonial Office will be called upon to undertake in increasing measure in the scientific and concurrent pursuit of the twin aims of development and welfare. Coming at a time when the Trusteeship Council of the United Nations has commenced its task of ensuring the progressive advancement of the many millions of non-self-governing peoples inhabiting the trustee territories, it indicates that, in the Colonial revolution now proceeding, Great Britain will be in the van of progress, and that neither boldness nor imagination will be lacking from her administration of dependent territories. The dual mandate conception of Lord Lugard has entered on a further phase, and one in which the contribution of science will be of growing importance.

This is brought out specifically in two sections of the report itself. Observing that the opportunity which the project provides for introducing measures for the prevention of disease and for desirable standards of nutrition, the report urges that the possibilities should be brought to the notice of the Medical Research Council and its Human Nutrition Research Unit. Similarly, the Colonial Social Science Research Council may wish to consider the wider implications of the project, while the report envisages the creation, at the outset, of a research section of the undertaking, and in accepting the scheme the Government slightly increased the provision for central administration and research installations. The primary task of the research section in the earlier years will be to conduct research and trials to facilitate the maximum economic production of ground-nuts by the use of liming materials, fertilizers, suitable varieties, methods of soil conservation and rotation, and for the control of disease. This work can be planned in such a way as to provide basic data on problems of soil crops in East Africa, thus aiding research on these problems undertaken in the East African Agricultural Departments and at the Central Research Station for East Africa at Amani.

In later years, work in these fields will be extended to include more fundamental aspects. Studies of the production of other food crops, for example, should be linked with nutritional studies and planning, if the project is to make its fullest contribution to the solution of African problems. Veterinary problems will arise as control of the tsetse fly makes possible the introduction of animal husbandry, while, as social and economic research and planning become important, the investigation of natural resources and power supplies for industrial development would follow.

The scientific programme contemplated for the first two years includes meteorology, soil fertility studies, soil survey and mapping, crop disease survey and variety testing. A central meteorological station will be required at each main centre, and appointment of an entomologist with ecological training for study of the tsetse fly, especially in relation to bush clearance and other problems, is desirable. A pathological laboratory will be necessary for the medical service, and a nutrition adviser should be appointed, as well as a statistician and a soil chemist, competent, in conjunction with the surveying of the units, to carry out the mapping of the main soil types in the areas concerned.

For the third year the programme envisages the continuance of fertilizer work and study of the effect of incorporating humus and of conservation work on the moisture content of the soil, as well as experiments on crop rotations, including studies of the fate of nutrient elements in the soil, particularly nitrogen. The testing of alternative fertilizer materials and methods of application; the suitability of local materials for fertilizer manufacture and other industrial purposes; the investigation of water conservation problems, including drainage, on a 'geographical' scale; positive programmes of plant-breeding for resistance to disease and yield of oil; and the acclimatization of new crops, particularly of fruit and vegetables, are other directions in which research is regarded as likely to yield results of value to East Africa as a whole. In the veterinary field, studies of cattle nutrition are contemplated, and pasture studies should develop from the botanical survey of the earlier years.

This programme indicates the fundamental importance of the contribution of science to the success of the scheme, and on that ground alone the proposals and the report formulating them merit careful study by scientific workers concerned with these fields. Beyond this and beyond the importance of co-operation between men of science and scientific departments in many fields—the Rhodes - Livingstone Institute, as well as the Colonial Research Committee, the Medical Research Council and several Government Departments are all in a position to make invaluable and indispensable contributions—there is the great human interest which is attached to this experiment in human welfare. It is a programme the implications of which reach far beyond the Colonial field itself, and may provide a demonstration of the power of science to contribute to the improvement of standards of living and to increase the resources of mankind. It may open up increasing possibilities in the use of science for the welfare and not the destruction of mankind, and the fulfilment of the hopes which the vision and imagination of such schemes as the Tennessee Valley Authority and the Food and Agriculture Organisation of the United Nations have already raised.

RICHARD JEFFERIES AND THE ENGLISH FARM WORKER

A Classic of English Farming

Hodge and his Masters. By Richard Jefferies. Edited and with an Introduction by Henry Williamson. Pp. 340. (London: Faber and Faber, Ltd., 1946.) 10*s*. 6*d*. net.

IN 1872 there appeared in *The Times* a long and remarkable letter describing the life of a Wiltshire farm labourer. It was so different from the current ideas on the subject that it was drastically criticized by the *Liverpool Mercury*: "A Mr. Richard Jefferies, dating from Coate Farm, Swindon, has managed somehow or other to get two columns and a quarter of the *Times* to air his notions in, and very funny notions they seem to be—there is no doubt that he has moved about amongst hundreds of labourers; but that he has ever adequately seen them in the sense of understanding and knowing them we should be very slow to believe". But Jefferies was not crushed, and seven years later, in 1879, he wrote a series of articles on country life which were published in book form in 1880 under the title "Hodge and his Masters". For some reason or other the book was not re-issued until 1937. Messrs. Faber and Faber have now re-published it with an introduction by Mr. Henry Williamson, who has wisely reprinted the original *Times* letter and the *Liverpool Mercury*'s criticism thereon.

The book was well worth reprinting, for it gives a graphic picture of the Wiltshire countryside in the 1870's, written in Jefferies' usual limpid style and with his unerring instinct for getting at the essentials and yet including sufficient detail to make the picture vivid. He attempts no running narrative; each chapter is self-contained and almost independent of the rest, and there is no final summing up. But all the same, the account is wonderfully clear, and all of Hodge's 'masters' are described in their turn. Hodge is, of course, the farm worker; the masters are the farmer, the squire, the parson, the County Court officials, and at the end, the Board of Guardians, for Hodge, much against his will, ended his days in the workhouse; his wife was dead, his children had emigrated, and the Guardians were precluded from giving outdoor relief by the circumstances that Hodge had saved a little and become part owner of his cottage.

The book was written in 1879—the worst season on record because of heavy persistent rain from hay-time to harvest and beyond. The results were disastrous: the corn gave wretchedly low yields of very poor quality, the land became smothered in weeds, hay became scarce and very dear, the grass was sodden and of desperately poor feeding value, livestock were ill-nourished and disease was widespread. All this is vividly described, but not too gloomily, for there is a stolidity about the countryman, which Jefferies faithfully reproduces, that makes him slow to recognize disaster. Had 1879 stood alone, the damage might well have been repaired, but it was followed by a run of bad seasons and, worse still, wheat began to pour in from North America in unregulated flow, and meat followed suit, so that prices fell and many farmers were ruined. The chapter "Going Downhill" is one of the saddest in the book.

The vividness with which the essential features are described gives the book a very modern feeling. Over and over again one is tempted to forget that it was written in 1879 and not in 1946. The stress laid on the need for mechanization, the talks about artificial manures and hay-driers, the man who, having acquired wealth in the city, sets up as a farmer and proceeds to introduce business methods, but becomes for half the countryside an object of lawful plunder—and loses heavily in consequence—all these appear just as they would if Jefferies had been writing to-day. Happily the modern changes in the countryside, some good, some bad, have not destroyed its fundamental good features. Perhaps most important of all, the sense of responsibility to the land, the live-stock and the community remains; fortunately indeed for us, for it has meant that the output per man-year has increased since 1939 by some 17 per cent, and throughout all that critical period there was no threat of action by the workers against the community. No other primary producers can show such a record: if they could, the nation would not be in its present predicament.

The book can be strongly recommended to all lovers of the English countryside. If a second edition is called for, we hope that editor or publishers will tell us more about Richard Jefferies, for, sad to say, many young people to-day know very little about him; some indeed have never heard of him. But his work deserves to live.

E. John Russell

A TEXT-BOOK FOR ANÆSTHETISTS

The Chemistry of Anaesthesia

By Dr. John Adriani. Pp. ix+530. (Oxford: Blackwell Scientific Publications, Ltd., 1946.) 35*s*. net.

MEDICAL men seeking special qualifications as anæsthetists are expected to acquire a good knowledge of the basic sciences on which anæsthesia depends. A pair of text-books on the physics and chemistry of anæsthesia for use by intending anæsthetists has been published by Blackwell Scientific Publications of Oxford. The author of the present volume, John Adriani, is director of the department of anæsthesia in the Charity Hospital of Louisiana at New Orleans.

The first hundred pages are devoted to inorganic chemistry, including the physical and chemical properties of the gases present in the atmosphere, the principles of flowmeters, absorption apparatus and other equipment used by anæsthetists.

The next two hundred pages give a detailed account of the chemical properties of general anæsthetics and of other drugs used by anæsthetists, including hypnotics, opium alkaloids, local anæsthetics, drugs affecting the autonomic system and analeptics. There are a number of tables giving the chemical formulæ of allied drugs in a form which makes it easy to compare them with one another. This section of the book will be useful for reference, but it is to be hoped that anæsthetists will not be expected to memorize all these detailed facts, most of which will be of little direct use in the practice of their art.

The last two hundred pages deal with the pharmacology of general anæsthesia, with a chapter on local anæsthesia and another on enzymes, vitamins and hormones. This section will be more valuable to anæsthetists than the rest of the book and may interest readers of *Nature*. The various theories of narcosis are impartially set forth. The effects of anæsthesia on the body fluids are discussed, with sufficient information on biochemistry to make the discussion intelligible to those medical men who have forgotten most of what they learned in the earlier parts of their time as students. Chapters are devoted to the physiology of the liver and the kidneys, with an account of the effects of anæsthetics upon them. There is a short account of methods used to estimate the effect of anæsthetics on tissues, and of the fate of anæsthetics in the body.

The book will probably find a market because it provides the information required for one type of examination in a form that is not otherwise available; but it contains a number of errors. For example, the formula on p. 235 for the rate of disappearance of an anæsthetic in the body must surely have been incorrectly copied. The numbering of atoms in the purine ring on p. 278 is not the usual one and does not correspond with chemical names in the text. On p. 289 a unit of pituitrin is defined as the amount required to raise the blood pressure of a dog by 30 per cent. Anyone who knows anything about biological assays is likely to be deeply shocked at this last statement.

There are forty-five pages of reference at the end, arranged according to the chapter, or part of a chapter, in which each work is mentioned. This system is not uncommon, but inconvenient. The reader who wishes to trace a reference must first find out which chapter he is reading by noting the page and referring to the list of contents at the beginning. He must then find the corresponding section of the list of references, and if he opens the book in the middle of one of these sections there is no indication whether he should turn on or back. This list would be easier to use if it contained, on each page, the numbers of the corresponding page of the text.

RESEARCH IN CANADA

Research in Canada

Planning for the Coming Years. Papers given at the Symposium of the Chemical Institute of Canada, Quebec City, June 1945. Pp. vii + 160. (Sarnia, Ont.: Imperial Oil, Ltd., 1946.)

THE papers in this volume, sponsored by Imperial Oil, Ltd., were presented at the first annual conference of the Chemical Institute of Canada, held at Quebec in June 1945, and although, as might be expected, of uneven merit, afford a conspectus of scientific research in Canada in some respects broader than that given by the annual reports of the National Research Council. Dr. C. J. Mackenzie's contribution, "Government Sponsored Research", goes far beyond the narrower limits which his position as president of that Council might impose, and he discusses the particular problem of the industrial research association in Canada in view of the relatively few large industrial units in Canada. Dr. Mackenzie looks forward to the activities of Government-sponsored laboratories, such as those of the National Research Council, being directed almost exclusively to the more fundamental aspects of applied research; but he indicates that in the meantime the National Research Council will foster industrial research either on a co-operative basis or through agencies of the type of the Mellon Institute. Dr. R. K. Stratford, chief research chemist of Imperial Oil, Ltd., in his contribution "The Co-ordination of Research in Canada", also discusses the relations between fundamental and applied research, emphasizing the importance of maintaining a reasonable balance between the man-power engaged in industrial research and in fundamental research in the universities; and he suggests the establishment of technical institutes to help co-ordinate and improve the efficiency of technical men engaged in field service or development work, a suggestion which is elaborated in some detail by Prof. P. Rion.

"The Role of the Universities in Research" is discussed more particularly by Prof. L. Thomson, who endorses Dr. Stratford's view as to their primary importance, but emphasizes that they are equally the source of expert personnel required in government and industry. Prof. Thomson goes on to emphasize the factors on which the effectiveness of the universities both for teaching and research depend, and stresses not only adequate financial support but also the provision of conditions of service to attract the best men, as does Mr. G. E. Jackson in a paper on "The Provision of Manpower for Research in Canada". Much in these and in the other papers reiterates points made repeatedly in discussions on scientific and industrial research in Great Britain in recent years and in the Barlow Report on scientific staff.

The most interesting paper is possibly that by Dr. H. G. Fox on "Research and Invention in the Law of Patents", in connexion with which attention may be directed to Mr. C. Hollins' discussion of "Patentable Invention" (*Chemistry and Industry*, 170; 1945). After dismissing as invalid in the light of Canadian experience Mr. Wendell Berge's assertion that patents have been used to stifle new enterprise and to limit capacity and production, he proceeds to review the Canadian patent system in relation to research. The situation, he holds, is not entirely satisfactory, first because of faulty administration, due largely to inadequate staffing and parsimonious grants from the Canadian Government—weaknesses which, incidentally, are obvious even outside Canada to anyone who has had dealings with the Canadian Patent Office—and, second, because of its insistence upon invention as a basis of grant of a patent. Dr. Fox develops at some length the implications of this doctrine, which he regards as inimical to organised research and team-work. He agrees that to provide the judges in patent cases with a panel of scientifically or technically qualified persons, as suggested by the Joint Chemical Committee, would assist; but urges that the only satisfactory solution is reform of the law itself to eliminate the criterion of invention and replace it by that of improvement, providing protection where a contrivance or discovery is new and useful, contributing something to the technique of scientific or industrial life or representing a step forward in art. Dr. Fox's history of the outlook on subject-matter is valuable and interesting; but it should be observed that the decline in patent activity illustrated by the graph on p. 86 and referred to on p. 115 is not peculiar to Canada. A corresponding decline is apparent at least up to 1939 in the major industrial countries, including the United Kingdom and Germany as well as the United States. Two minor corrections should be noted. The reference on p. 117 should be to the Trade Marks, Patent and Designs Federation, Ltd., while on p. 118 "Joint Chemical Society" should read "Joint Chemical Committee".

R. Brightman

Annuaire astronomique et météorologique Camille Flammarion pour 1947

(83e année.) Pp. 381. (Paris: Ernest Flammarion, 1947.) 160 francs.

THE *Annuaire* for 1947 follows the usual plan of earlier issues, with a few minor modifications, and maintains its excellent standard. It may be pointed out that amateur astronomers, who are playing an increasing part in astronomical developments, would find this publication a very useful handbook as complementary to the "Nautical Almanac". Much of the information is tabulated in a very concise and convenient manner, and also various branches are dealt with which are outside the scope of the "Nautical Almanac". Thus, lists of comets, meteor radiants, distances, spectral classes, temperatures, diameters of stars, of variable stars, etc., and also interesting phenomena for each day, provide very handy material for amateurs who might otherwise find it necessary to search different books of reference for such information. Members of the British Astronomical Association, who depend on the Association's Handbook for data on different sides of astronomy, would find the *Annuaire* a useful addition to their bookshelves. Star maps for each month of the year will prove acceptable to many readers.

The portion dealing with terrestrial magnetism and meteorology is very short, the latter occupying less than three pages. One wonders whether this could not be enlarged a little, with some advantage to certain readers. As pointed out, however, on p. 19, it is very unlikely that this will be done in the near future, and only in so far as meteorology makes substantial progress can it claim the right to be included in the *Annuaire*. Four pages are devoted to the physics of the earth, and these deal solely with seismic disturbances in France and other countries.

M. D.

General Chemistry

By Prof. Eugene P. Schoch, Prof. William A. Felsing and Prof. George W. Watt. (International Chemical Series.) Pp. xiii+540. (New York and London: McGraw-Hill Book Co., Inc., 1946.) 20*s*.

THIS is an elementary text-book on the lines of most good American works of its kind. The material is presented in a selected order, in many cases the elements being separated from their compounds in different chapters, and there is emphasis on industrial uses. The chapters on physical chemistry are interspersed among those on inorganic chemistry, and on the whole the book lays more emphasis on this side. In some cases the sections on inorganic chemistry are very short, ozone having only one page, for example. There is a whole chapter on nuclear chemistry, and four chapters on selected topics in organic chemistry. There are references to American literature, and questions, at the ends of the chapters.

Since the book is in a second edition, it is in general accurate, but a few slips were noticed. It is surely incorrect to emphasize so strongly (p. 40) that a catalyst in a reaction "has not been altered in any way", and this is probably incorrect for the reaction dealt with. Chlorine dioxide does not, as was proved by the American chemist Bray long ago, react with water to form chlorous and chloric acids (p. 397, where the formula of chlorine dioxide is given as Cl_2O in the equation). The old chain formulæ of the sugars are given (p. 480). The portrait on p. 491 is of the wrong Perkin.

These are trifling errors, and the book as a whole is carefully written and based on modern theory. The sections on oxidation-reduction reactions, acids and bases, and electrochemistry may be mentioned as especially good. Although the book would be found interesting by teachers, it would not fit into English courses; some subjects are dealt with too summarily, and some in much too detailed a way.

Tables of the Modified Hankel Functions of Order One-Third and of their Derivatives

By the Staff of the Computation Laboratory. (Annals of the Computation Laboratory of Harvard University, Vol. 2.) Pp. xxxvi+235. (Cambridge, Mass.: Harvard University Press; London: Oxford University Press, 1945.) 10 dollars. 55*s*.

THE new I.B.M. Automatic Sequence Controlled Calculator at Harvard was recently described in *Nature* (**158**, 567; 1946). The volume now before us contains the first of a series of tables produced by the machine in its spare time!

The differential equation the solutions of which are tabulated is that of Stokes, namely,

$$\frac{d^2u}{dz^2} + zu = 0,$$

which occurs in problems of wave propagation. Solutions of this equation for real z have recently been tabulated under the direction of J. C. P. Miller (B.A. Mathematical Tables, Part-Volume B, 1946) as the Airy integral.

Although the general solution of this equation can be written in terms of Bessel functions of order one-third, the direct tabulation, as is here done, is preferable. The real and imaginary parts of two fundamental solutions are given to eight decimals at intervals of 0·1 in x and y up to $|x + iy| \leqslant 6$.

The next tables to appear in this series are of $J_n(x)$ at a fine interval and to high values of n and x.

L. J. COMRIE

Characterisation of Organic Compounds

By Dr. F. Wild. Pp. viii+306. (Cambridge: At the University Press, 1947.) 18*s*. net.

ADVANCED students of organic chemistry and also research workers in this field will find in Dr. Wild's book a useful and comprehensive guide in the characterization and identification of organic compounds belonging to most of the ordinary types. The work is essentially for use in the laboratory; it affords practical details, either directly or through references to the literature, for the preparation of suitable derivatives and of the special reagents needed; and there are reference tables for each important type of characterizing compound described. Details for the preparation and application of some of the newer and less familiar reagents are particularly useful. As an example of the treatment adopted, the preparation of solid derivatives of alcohols is described, within the compass of eleven pages, by means of esterification with acid chlorides, isocyanates, azides, acid anhydrides and pseudo-saccharin chloride; several miscellaneous methods follow. An appended table gives the boiling-point or melting-point of the original substance and of a maximum of fourteen derivatives for a list of fifty-seven alcohols. The book is well documented, indexed and printed. An introductory section contains eleven diagrams of apparatus.

J. R.

ACOUSTICAL QUANTA AND THE THEORY OF HEARING

By Dr. D. GABOR
British Thomson-Houston Co. Research Laboratory, Rugby

IN popular expositions of wave mechanics, acoustical illustrations have been used by several authors, with particular success by Landé[1]. In a recent paper on the "Theory of Communication"[2] I have taken the opposite course. Acoustical phenomena are discussed by mathematical methods closely related to those of quantum theory. While in physical acoustics a new formal approach to old problems cannot be expected to reveal much that is not already known, the position in subjective acoustics is rather different. In fact, the new methods have already proved their heuristic value, and can be expected to throw more light on the theory of hearing. In my original paper the point of view was mainly that of communication engineering; in the following survey I have emphasized those features which may be of interest to physicists and to physiologists.

What do we hear? The answer of the standard text-books is one which few students, if any, can ever have accepted without a grain of salt. According to the theory chiefly connected with the names of Ohm and Helmholtz, the ear analyses the sound into its spectral components, and our sensations are made up of the Fourier components, or rather of their absolute values. But Fourier analysis is a timeless description, in terms of exactly periodic waves of infinite duration. On the other hand, it is our most elementary experience that sound has a time pattern as well as a frequency pattern. This duality of our sensations finds no expression either in the description of sound as a signal $s(t)$ in function of time, or in its representation by Fourier components $S(f)$. A mathematical description is wanted which *ab ovo* takes account of this duality. Let us therefore consider both time and frequency as co-ordinates of sound, and see what meaning can be given to such a representation.

If t and f are laid down as orthogonal co-ordinates, a diagram is obtained which may be called an 'information diagram' (Fig. 1). A simple harmonic oscillation is represented by a vertical line with abscissa f, a sharp pulse (delta function) by a horizontal line at the 'epoch' t. These are extreme cases. In general, signals cannot be represented by lines; but it is possible to associate with them a certain characteristic rectangle or 'cell' by the following process, which at first sight might perhaps appear somewhat complicated.

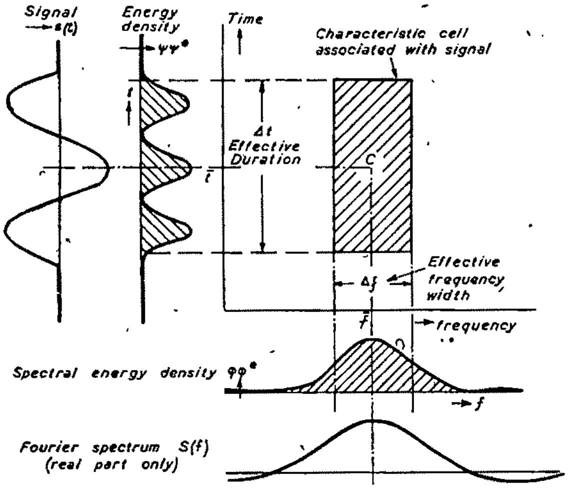

Fig. 1. CHARACTERISTIC RECTANGLE OF A SIGNAL IN THE INFORMATION DIAGRAM

Consider a given signal described as $s(t)$ in 'time language' and by its Fourier transform $S(f)$ in 'frequency language'. If $s(f)$ is real, $S(f)$ will be in general complex, and the spectrum will extend over both positive and negative frequencies. This creates an unwelcome asymmetry between the two representations, which can be eliminated by operating with a complex signal $\psi(t) = s(t) + i\sigma(t)$, where $\sigma(t)$ is the Hilbert transform of $s(t)$, instead of with the real signal $s(t)$. This choice makes the Fourier transform $\varphi(f)$ of $\psi(t)$ zero for all negative frequencies. Next we define the 'energy density' of the signal as $\psi\psi^*$, where the asterisk denotes the conjugate complex value, and similarly $\varphi\varphi^*$ as the spectral energy density. In Fig. 1 the two energy distributions are shown as shaded areas. The two are of equal size; that is, the total energy of the signal is the same by both definitions. We can now define a 'mean epoch' $\bar{t}$ of the signal, and similarly a 'mean frequency' $\bar{f}$, as the co-ordinates of the centres of gravity of the two distributions. This gives a point C in the information diagram as the centre of the signal. Going a step further, we define the 'effective duration' Δt and the 'effective frequency width' Δf of the signal by means of the mean square deviations of the two energy distributions from the mean values $\bar{t}$ and $\bar{f}$. In the figure these appear as the inertial radii of the two shaded areas. For reasons which will become evident later, it is convenient to define Δt and Δf as $2\sqrt{\pi}$ times the respective inertial radii†. With these definitions a mathematical relation, the Schwarz inequality, can be applied, which states that

$$\Delta t \, \Delta f \geqslant 1 \; ; \quad . \quad . \quad . \quad (1)$$

that is to say, *the area of the characteristic rectangle or cell of a signal is at least unity*. This is the exact formulation of the uncertainty relation between time and frequency. It is clear now that what we have obtained is a classical model of one-dimensional static wave mechanics, in which unity replaces Planck's constant h. Formally this 'quantum' is represented by a cell of unit (dimensionless) area in the information diagram. Its physical significance becomes evident from the following consideration.

If in a time interval T a signal is expanded in a Fourier series, there will be T complex Fourier components per unit frequency band-width. Thus we can say that the information diagram contains one complex datum per unit area. (This, of course, is to be considered as an asymptotic theorem for large areas, as by equation (1) we cannot analyse the information area into cells of less than unit order.) We see now that the quanta in this model of wave mechanics are *quanta of information*. Each quantum represents one complex numerical datum or two real data.

This result, in combination with the uncertainty relation (1), suggests the question whether there are signals for which the inequality turns into an equality, and which could be used for the representation of quanta. It can be shown that such simplest or 'elementary' signals exist, and their form is

$$s(t) = \exp - \alpha^2(t - t_0)^2 \, . \exp i2\pi f_0 t, \qquad (2)$$

---

† In the original paper the factor was $\sqrt{2\pi}$ instead of $2\sqrt{\pi}$, so that $\frac{1}{2}$ appears in equation 1 instead of unity. The present choice is more advantageous for a direct comparison with quantum theory.

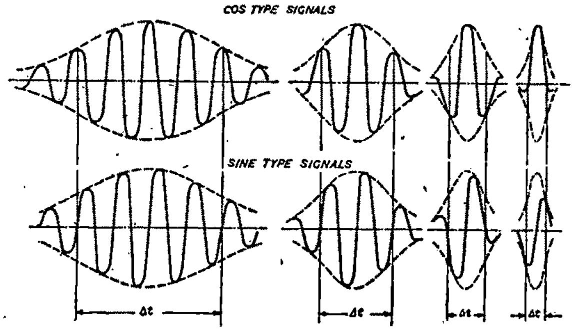

Fig. 2. ELEMENTARY SIGNALS

where α is a real constant. Thus the elementary signals are harmonic oscillations of any frequency f_0, modulated by a probability pulse. Their Fourier transforms are of the same mathematical form

$$S(f) = \exp - (\pi/\alpha)^2(f - f_0)^2 \cdot \exp i2\pi t_0 f. \quad (3)$$

The real components of the elementary signals are conveniently specified as cosine-type and sine-type signals, and are illustrated in Fig. 2 for several values of the constant α, which is connected with the effective duration and effective band-width by the equations $\Delta t = \sqrt{\pi}/\alpha$ and $\Delta f = \alpha/\sqrt{\pi}$. If $\alpha = 0$, the elementary signals become simple harmonic oscillations; if $\alpha = \infty$, they turn into the delta function and its derivative.

These elementary signals can be used for the representation of quanta of information, as any arbitrary signal can be expanded in terms of them, with any choice of the constant α. That is to say, we can expand a signal by dividing up the information area into unit rectangular cells of any aspect $\Delta t/\Delta f = \pi/\alpha^2$, and by associating with every cell an elementary signal with a complex amplitude factor c_{ik}. We thus obtain a sort of matrix, as illustrated in Fig. 3. This method of analysis contains 'time language' and 'frequency language' as special extreme cases. If the cells are infinite in the time direction we obtain Fourier analysis; if they are infinite in the frequency direction we obtain an expansion into delta functions, that is to say, the function $s(t)$ itself.

Expansion into elementary functions is in general a rather inconvenient mathematical process, as they do not form an orthogonal set. There exists, however, an experimental method, which, though not equivalent, gives somewhat similar and very valuable results. This is the method of 'sound spectrography' developed by the Bell Telephone Laboratories during the War, and published after the original paper by the author was written and accepted[3]. There is no space here to describe this method and the difference between 'sound portraits' and matrices of elementary signals, but it may be noted that sound portraits are not complete representations of the original sound, though they contain most of its subjectively important features.

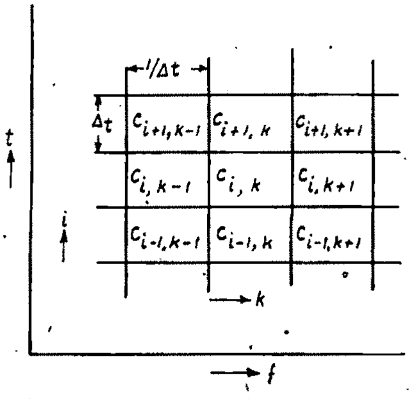

Fig. 3. MATRIX OF ELEMENTARY SIGNALS REPRESENTING AN ARBITRARY SIGNAL

It is to be expected that the analysis of hearing sensations will prove a fruitful field for the new methods of representation, and the results so far obtained seem to indicate very clearly that the 'quantum of sound' is a concept of considerable physiological significance. Acoustical workers have collected a large amount of material on the threshold of ear discrimination for epoch and frequency differences. It appears that at least a good part of these results can be summed up in the statement that *the ear possesses a threshold area of discrimination of the order unity.*

One series of experiments which were analysed were those of Bürck, Kotowski and Lichte[4]. Their object was the threshold of time discrimination in different frequency-ranges. Mach showed that if a sinoidal oscillation is sounded for a few cycles only, the ear will hear it as a noise, while after a minimum duration of about 10 milliseconds it will be heard as a short musical note, with ascertainable frequency. The authors carried out a series of tests on this phenomenon, and in a second series° went a step further. In these tests the intensity was doubled after a certain time from the start. If this was less than a certain minimum (21 msec. at 500 cycles), the sound could not be distinguished from a note which was sounded from the start with double intensity; beyond this the step could be heard as such. One could say that in the interval between 10 and 21 msec. the ear has just got ready to register a second, distinct sensation.

Another series of experiments is due to Shower and Biddulph[5] and relates to the threshold of differential frequency discrimination of the ear. Their technique was quite different. The frequency of a note was modulated between narrow limits, and the minimum frequency swing was noted which gave the impression of a 'trill'. At 500 cycles this minimum swing was 2·3 cycles. Below this the trill could not be distinguished from a pure note. The cycle of modulation was so chosen that it gave the finest frequency discrimination (0·5 sec. for the full cycle). In these experiments, as in those of Bürck, Kotowski and Lichte, intensity played no essential part, provided that the tests were carried out at a level of good audibility.

Though it might appear that in these experiments the frequency discrimination of the ear was tested, and in the previously mentioned experiments the time response of the ear, in reality, of course, both time and frequency are involved in both cases. In the experiments of Bürck, Kotowski and Lichte, the effective width of a sinoidal oscillation which has lasted only for a finite time has to be considered. In the tests by Shower and Biddulph the time of 0·25 sec. is necessary to notice one 'up' or 'down' of the frequency. Thus from the time and frequency intervals involved in each case it is possible to form a product, the 'threshold area', in which the ear was capable of registering one sensation only, and which must be exceeded if it is to register a second. The numerical value of this area is to some extent a matter of definition. With the conventions adopted in the original paper, the threshold area calculated from the data of Bürck, Kotowski and Lichte was 1·05 at 500 cycles and 1·5 at 1,000 cycles, while the figures of Shower and Biddulph gave 1·17 in both cases. No such accuracy can of course be claimed, and the absolute values depend on the exact definition, but by any reasonable convention the threshold area is found to be of the order unity, that is to say, near the 'acoustical quantum limit'. It must be understood, of course, that there is an important difference between an acoustical quantum as registered by a physical measuring instrument, and as registered by the ear. In the experiments considered the ear was called upon only to answer 'yes' or 'no' to a simple question. To a measuring instrument, on the other hand, a quantum of information conveys a complex numerical datum (two real data), and every exact datum carries in itself an infinite number of 'yes's' and 'no's'. The difference is expressed by talking of 'discrimination' in the case of the ear and 'registering' in the case of a measuring instrument. In this sense we can say that, at least in simple experiments, the best ears in the optimum frequency-range can just about discriminate one acoustical quantum.

The importance of this result lies in the remarkably wide range of aspect ratios in which it seems to apply. As shown in Fig. 4 for the case of signals near 500 cycles, the threshold area does not vary appreciably while the time interval varies from about 20 to 250 msec.; that is to say, by more than a factor of ten. Within these wide limits the ear has the power of searching out by an automatic adjustment the finest details in the sound pattern offered to it. If a short sound strikes the ear, with poorly defined frequency, the time discrimination is of the order of 20 msec. If the sound is prolonged, so that its effective band-width shrinks to a few cycles per second only, the frequency discrimination of the ear keeps in step with this process for at least a quarter of a second. An old problem of physiological acoustics appears here in particularly sharp relief. No simple physical system of resonators could account for this degree of perfection. Resonators can be tuned to wide bands or to narrow ones, but not to both simultaneously. From physiological data, and in particular from the experiments of Wegel and Lane[6] on 'masking', it is practically certain that the ear resonators are very strongly damped, with decay times of the order of 10 msec. or less. They are tuned to bands approximately as wide as would account for the results of Bürck, Kotowski and Lichte, but not for those of Shower and Biddulph, which would require for their explanation decay times at least ten times longer. Thus the postulation of a second mechanism in the ear, which accounts for its apparent progressively refined tuning in the case of prolonged sounds, appears to be inescapable.

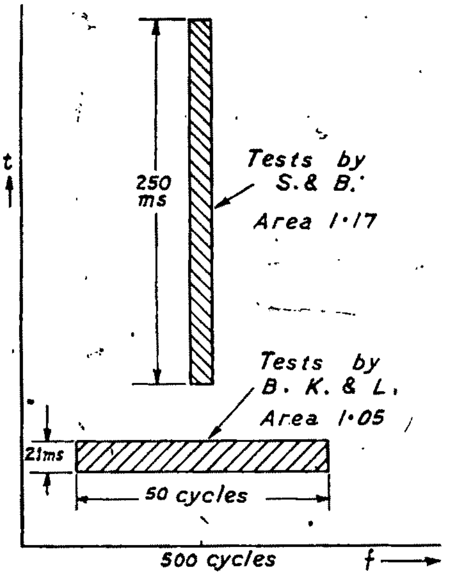

Fig. 4. THRESHOLD AREAS OF THE EAR AT 500 CYCLES/SEC.

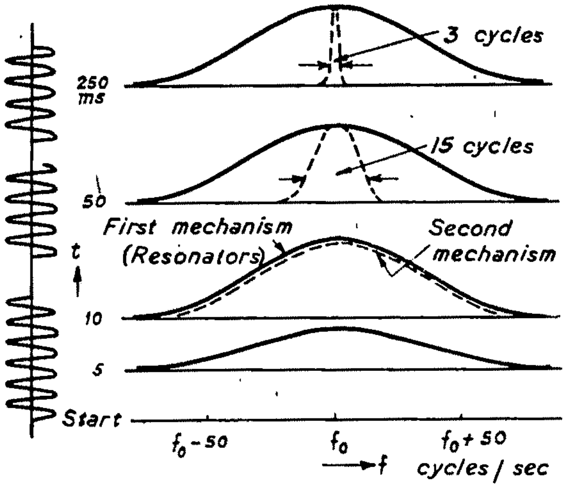

Fig. 5. THE TWO MECHANISMS OF HEARING. IF A NOTE IS SOUNDED FOR MORE THAN ABOUT 10 MSEC. THE RESONANCE PATTERN OF THE INNER EAR REMAINS UNCHANGED; BUT A SECOND MECHANISM STARTS SEARCHING FOR THE MAXIMUM OF EXCITATION AND LOCATES IT WITH AN ACCURACY WHICH INCREASES UP TO ABOUT 250 MSEC.

The role of the two 'mechanisms' is roughly illustrated in Fig. 5. The first is probably the real mechanism of the ear resonators; the second is almost certainly non-mechanical. One might be tempted to locate it in the brain, but this assumption is not unavoidable. It might well be a new phenomenon in nervous conduction, and could be explained by the hypothesis that conduction in adjacent nerve fibres is to some extent unstable, so that the more strongly excited fibre gradually suppresses the excitation of its less strongly excited neighbour. Thus if a pure note is sounded for a sufficient time, less and less fibres will be excited, until finally only the fibre corresponding to the position of maximum amplitude in the basilar membrane remains in action. This makes it possible to ascertain the frequency with far greater accuracy than one would expect from the broad tuning of the mechanical resonators. It would be most interesting, though probably very difficult, to prove or to disprove this effect, perhaps by a further refinement of the techniques of Galambos and Davis[7].

It is interesting to note that we begin to perceive a sound as 'musical' just at the point where the second mechanism takes over. Speech would be perfectly intelligible by the first mechanism alone; but the second is necessary to enable us to appreciate music.

Finally, it may be asked whether quantum theory has anything to learn from the acoustical model. In a formal sense the answer must be, of course, in the negative. From the fact, however, that two different fields admit the same formal treatment it follows that, so far as the mathematics goes, there can be nothing in one which is not implicit in the other. But familiar models of less familiar phenomena have at least one advantage. They make it easier to distinguish between intrinsic features of the phenomenon, and others which are introduced by the method of analysis. One might be inclined to think that sharply defined states, characterized by integral numbers, are peculiar to quantum phenomena, or at least that they require special mechanisms to imitate them classically, such as strings or membranes. But we have seen that in the acoustical model the integers emerge as a part of the mathematical background before any physical phenomenon has appeared on the stage. The ultimate reason for the emergence of 'acoustical quanta' is that we have viewed the same phenomenon simultaneously from two different aspects, and described it by two 'quantities of interest', time and frequency. Any number of other classical models may be found, if only we ask simultaneously two kinds of questions about the same thing, or perform two lines of experiments on it, provided that the questions are neither identical nor independent.

A CHEMICAL BICENTENARY AT THE UNIVERSITY OF GLASGOW

By Dr. ANDREW KENT
Department of Chemistry, University of Glasgow

ARISTOTELIAN physics and astronomy had had place in the arts curriculum at the College of Glasgow ever since King Jamie wi' the Fiery Face welcomed the advent of Scotland's second University (1451). In the eighteenth century a more modern science was recognized by the institution of chairs in natural philosophy (1717) and practical astronomy (1760).

Between these events in the Faculty of Arts, William Cullen completed the first course of lectures in chemistry (1747). This lectureship in the Faculty of Medicine was part of a renewed and finally successful effort to provide his *Alma Mater* with the prestige of a comprehensive medical school, the steady expansions of which included the later regius chair of chemistry (1818).

Cullen was perhaps the greatest physician to teach chemistry in this or any other British university. Although there is some evidence that he would have preferred to place the subject in the wider field of arts, there was, of course, nothing unusual in its association with eighteenth-century medicine. The notable factors are the broad and enlightened views which this polymathic personality adopted in the scope and emphasis of his teaching, and his lasting influence on the new department.

During 1747–1874 the Department was headed, for all but three years, by professional physicians. Although the degree of B.Sc. was first conferred in 1873, and the belated Faculty of Science (1893) included lectureships in organic chemistry (1898), in metallurgical chemistry (1899) and in "Physical Chemistry including Radio-activity" (1904), the chair of chemistry was first detailed in the calendar under 'Faculty of Science' only in 1920. Although even the nineteenth-century class of 'Practical Chemistry' pursued a course of "bases and acids, poisons and the pharmaceutical compounds", there was always a group of 'laymen' in the principal class of systematic chemistry and in the laboratory. For these freedoms of outlook and emphasis a lasting gratitude is due to William Cullen.

So the portentous association of Joseph Black (1756) with James Watt has its place in world history. John Robison (1766) was not a physician. William Irvine (1769) and T. C. Hope (1787) were physicists of note. Robert Cleghorn (1791) may have concentrated unduly on his duties to the students of medicine; but with Thomas Thomson (1817), the first regius professor, the lectures certainly reverted to a wider scope, which was undiminished during the tenure of his successor, Thomas Anderson (1852). With the advent of John Ferguson (1874) the medical dynasty is at an end: the now legendary 'Soda' took an active part in framing the new Faculty of Science, and in completing a near century of service by the first three regius professors. The fourth, G. G. Henderson (1919), guided the Department to its present Faculty. The 'auld alliance' has since been represented by a lecturer in 'Chemistry for students of Medicine' and by the research interests of George Barger (1937) and of James W. Cook (1939). In the Gardiner chair T. S. Patterson (1919) and J. Monteath Robertson (1942) have emphasized the modern significance of organic and of physical chemistry.

These heads of department, six of whom were products of the chemistry class, have seen their opportunities grow fiftyfold since some twenty students first gathered around Cullen. Since 1861 they have enjoyed the support of official colleagues such as, among others, William Ramsay, J. J. Dobbie, Frederick Soddy and C. H. Desch. The present teaching and research staff, some thirty strong, installed in a new and well-equipped building, have also behind them two hundred years of provocative tradition.

The Department has not only carried out its natal responsibilities in the teaching of medicine. It has helped to fashion in earlier days physician-scientists like Joseph Black, John MacLean of Princeton, and Thomas Graham, professional scientific workers like John Robison, William Thomson (Lord Kelvin) and (Sir) William Ramsay, *entrepreneurs* like Charles Macintosh and William Couper.

The Duke of Hamilton, descendant of Cullen's friend and patron, will preside over the first of a bicentenary series of lectures to be given this month by Dr. Douglas Guthrie, Prof. John Read, Dr. Alexander Fleck and Prof. A. R. Todd. Later, it is intended to publish a commemorative volume, edited by the present writer, in which scientific men of diverse interests and of many colleges will combine in tribute to those early pioneers whose far-sighted ambitions have eventuated in the multifold activities and the wide influence of the school of chemistry at the University of Glasgow.

The careless dust of time has overlaid some points of interest. It is not easy now to discover the type of chemistry taught by Cleghorn during a tenure of the lectureship (1791–1817) which included many exciting advances in the subject; an era much given to portraiture and cartoon has left no traceable reproduction of the lineaments of William Irvine; memorialists have often concentrated on the various medical chairs which were held concurrently or successively by the lecturers in chemistry. Enough remains to afford a reasonable pride in associations with hermetic antiquity.

Lavoisier and Dalton were to find paladins in Hope and Thomas Thomson, but Boerhaave and Stahl were the first pedagogic exemplars. If alchemy were never countenanced, the 'Four Elements' and the *Tria Prima* were topics of critical discussion in the earliest lectures. From that point onwards the making of modern chemistry is mirrored in the teaching and researches of its exponents at Glasgow, and in the later activities of those thousands whose names have been enrolled in the class of chemistry since 1747.

TAXONOMY OF AQUATIC INSECT NYMPHS AND LARVÆ

By Dr. T. T. MACAN

Laboratory of the Freshwater Biological Association,
Wray Castle, Ambleside, Westmorland

ALMOST any collection of freshwater animals will contain a high proportion of insects in the larval or nymphal stage, and a number of these cannot, at present, be named with certainty. The work of many biologists, whether their interest be in ecology, physiology or the food of fish, is affected by this gap in our knowledge, and the importance of closing it need not be stressed. It is the belief of the Freshwater Biological Association that, with sufficient co-operation from workers in other parts of the country, it should be possible, within a few years, to produce keys for the identification of the aquatic stages of all the important groups, except the Diptera. The purpose of this article is to appeal for this co-operation, to which end it includes brief notes on the existing systematic literature of the various groups and a short account of some of the methods of rearing adults from their nymphs or larvæ.

It is hoped that some workers in other laboratories may be induced to turn their attention to systematic studies, and the Freshwater Biological Association is prepared to give all the assistance it can. Others may be able to help by breeding out the species occurring in their own neighbourhood and sending the material to Wray Castle to be described.

The Ephemeroptera and Odonata are under investigation at the moment at Wray Castle. The most urgent need is the description of those species at present not described in any language; but it is also desirable to redescribe and figure some of the species already known, as almost all the existing literature is based on Continental material and the illustrations do not conform to a uniformly high standard.

The Coleoptera and Hemiptera, which are aquatic throughout life, are considered of less importance at the present moment. The position of the other main orders with aquatic nymphs or larvæ is as follows:

Plecoptera. Hynes[1] has described twenty-six out of the thirty-four probable British species, and two have been described since.

Ephemeroptera. Schoenemund's[2] key to the German species includes thirty of the forty-seven British species. Descriptions of some of the remaining seventeen are scattered through the literature. The biggest gap is the genus *Baëtis*, common and widespread in Britain and an important element in almost any stream or river. There are nine British species, but the nymphs of only three have been described, and one of these is probably associated with the wrong adult.

Odonata. Lucas[3] gives a key to the nymphs of all the British species, but experience at Wray Castle suggests that some of the species are distinguished on insufficient material, and the key does not always give the right answer. May[4] states that sufficient information to make a key to the subfamily Agrioninæ or the genus *Sympetrum* is not available. The group clearly requires further study.

Trichoptera. The most complete key, that given by Rousseau[5], is somewhat out of date. A revision of the larvæ of the group is being undertaken by Dr. N. E. Hickin, who has so far described some twenty of the British species (see Hickin[6] for list of references).

Diptera. Complete keys to some of the smaller families, for example, Culicidæ[7] and Simuliidæ[8] exist; others are among the least known of all the aquatic animals. The outstanding gap is the Chironomidæ, a very large family and one of great importance in freshwater biology. In spite of detailed work in Germany most larvæ can only be separated into species groups. Reference may be made to Goetghebuer and Lenz[9]. Separation into groups can also be effected by the use of Johannsen's[10] keys, although this author is primarily concerned with the American fauna.

Many Ephemeroptera and Plecoptera live in flowing water which is always cool and well oxygenated. Hynes[1] describes a technique for rearing the nymphs which are collected in such places, and the apparatus is figured by Worthington[11]. Series of flat enamel dishes are placed on sloping shelves one below the other. Water entering the top dish of each series from a tap drips from one dish to another. Each dish is provided with stones for the nymphs to cling to and is covered with a sheet of mosquito netting on a wire frame. It is necessary to transfer newly emerged Ephemeroptera to a small tube for a day or two, in order to allow the imago to emerge from the sub-imago. Both nymphal skins and adults should be preserved in 2½ per cent formalin, the adults being first wetted in 70 per cent alcohol.

Stream-dwelling Ephemeroptera have, however, been reared in stagnant conditions where a supply of river water was immediately available. Useful collections have also been made by catching emerging sub-imagines in the field. A large collection of nymphs is made; those which, from their silvery appearance, are evidently about to emerge, are sorted into a dish, the collection is then watched, and each sub-imago is caught as it emerges.

Most Odonata inhabit stagnant waters and are easier to rear. They may be kept in pie dishes without running water, one nymph to a dish or they will devour one another. A stick or piece of reed should be provided for the nymph to crawl up before emergence. Each dish should be covered by a cage, though, if this is not possible, and the dishes are in a room, of which the doors and windows can be kept closed, it is seldom that an adult is lost or cannot be associated with the skin from which it came. The adult should be caged for several days after emergence, so that the colours may develop. The brilliance of wild specimens is never attained by captives, but the colours develop sufficiently for systematic purposes. Adults and nymphal skins should be preserved in 70 per cent alcohol and kept in the dark.

The cast skins of exopterygote insects are sufficient for taxonomic purposes, but it is always desirable to have some preserved nymphs from the same locality.

Detailed descriptions of rearing techniques are given by Galtsoff *et al.*[12].

OBITUARIES

Prof. B. A. McSwiney, F.R.S.

In the sudden and most untimely death of B. A. McSwiney on March 8, physiology and physiologists have suffered a most grievous loss. At a time when enthusiasm, energy and wisdom are conjointly needed for the development of medical education and its safe progress in a period of transition, the University of London and the Medical School of St. Thomas's Hospital have lost a professor and a dean who possessed these qualities in abundance.

McSwiney's scientific career, apart from the war years, was largely orthodox. After a year as lecturer in Leeds, he became lecturer in experimental physiology in the University of Manchester and had the good fortune to work in that laboratory when, under the stimulus of A. V. Hill, it was awakening from a long sleep. His early publications reveal an interest in the development of apparatus for teaching and research which he never lost; but it was not until 1923 that he started working on two quite different subjects which eventually were to shape all his subsequent activity. With Crichton Bramwell and A. V. Hill he published a paper on the velocity of the pulse-wave in man, and a year later, with the late E. D. McCrea, J. W. Morison and J. S. B. Stopford, one on their work on the normal movements of the stomach.

The innervation of the stomach remained McSwiney's chosen interest, and into the morass of conflicting statements, bad experiments and misleading results which confuse the literature he plunged with unabated energy. His work has revealed many of the sources of error which have beset previous workers and has formed a firm scaffold of sound experiment within which others may build. It is of interest to follow the directions in which the problem of gastric innervation led him. He followed at one time the attractive by-path of the physiology of isolated smooth muscle; he developed an elegant nerve – smooth muscle preparation which permitted an approach to be made to the analysis of the peripheral interaction of vagal nerve volleys; and, at the other end of the scale, he and W. R. Spurrell developed a method of outlining the stomach so that its activity could be observed radiographically, without the disturbance and abnormality of an opaque meal.

But this was to take place some years hence. In the meantime, at Manchester, the University had decided to start an honours school of physiology, and it was in the intimate teaching of the chosen few that McSwiney reached his peak. He was obviously too good to last long as a lecturer, and in 1926 he was appointed to the chair of physiology in Leeds.

Here was a splendid opportunity; a relatively small department was ripe for development, and there was the prospect of the extension of the medical school at an early date. McSwiney set to with gusto to build a Physiology Department second to none in the provinces. The old building was reconstructed internally, and, in a few years time, a new building rose which bore the unmistakable stamp of the foresight, skill and energy of the prime mover in its completion. Yet in spite of this interest in bricks and mortar, he was building within his laboratory a research team of great potential. He paid the inevitable penalty of losing men as he made them, but it must have been a source of pride to him to know that eight of his staff at Leeds eventually went to chairs, or posts of equivalent rank. He paid again in the energy he expended, willingly and happily; but the result was a peculiarly happy and friendly laboratory.

It was towards the end of his stay in Leeds that McSwiney published a paper on the afferent fibres from the abdominal viscera. This was the first of a long series with a number of different collaborators, and in it McSwiney had obviously found the subject of his heart. The technique employed was apparently simple, suggesting that little more was needed than observation of the pupil and excitation of nerves by the homely pinch or an induction shock. It demanded, however, the exercise of the experimenter's full artistry to maintain the integrity of labile reflexes in animals exposed to extensive surgical interference, and a most rigid exclusion of a multitude of complicating factors. McSwiney and his colleagues were building a fine structure of knowledge on visceral afferent pathways, much of it with direct application to human medicine. It is to be hoped that his death has not brought the work to an end.

McSwiney left Leeds in 1936 to succeed the late John Mellanby as professor in the Sherrington School of Physiology, St. Thomas's Hospital, and here he set out to continue the work so successfully started in Leeds; but not for long, as he was soon involved in the turmoil of war and evacuation of the Medical School to Godalming. Ordinary research work came to a standstill, and his laboratory undertook practical problems of wound shock and oxygen therapy. With the return of peace his unflagging energies were devoted to the return of his medical school to its normal activities and to the repair of the spiritual and physical damages of war.

No comments on McSwiney's career would be complete without reference to the service which he gave to the Physiological Society. He became a member in 1920 and served on its committee during 1928–34. He was then elected treasurer of the Society, and fulfilled this onerous and responsible task for ten years, at a time when the rapid development of the Society demanded a wise and careful control of its finances. He was in this, as in so many of his activities, supremely competent and effective. His election to the Royal Society in 1944 held out the prospect of widening further the scope of the services he might give to science, great as they had already been.

In the memory of many, McSwiney will remain as an administrator and organiser; but good as he was at these tasks and great as was his flair for the strategy and tactics of the committee, his real place was as an inspiration and guide to his younger colleagues. He himself would never have claimed to be a great investigator, but those of us who had the privilege of working with him know that he had that peculiar quality of leadership which brought out the best in his collaborators in a happy spirit of comradeship.

G. L. BROWN

Prof. Gregori Aminoff

GREGORI AMINOFF, head of the Mineralogical Department of the Museum of Natural History (Riksmuseum), Stockholm, died on February 11, 1947. His death was caused by heart disease, which had during the last few years of his life greatly reduced his capacity for work.

Aminoff, who was born in 1883, belonged to an old Russian Boyar family, a member of which became a Swedish subject in the year 1612. He studied science in Stockholm and obtained his first academic degree in Uppsala in 1905. A strong artistic inclination caused him then to change his profession, and for several years he practised as an artist and studied art in France and Italy. About 1913 his old interest in science became predominant, with the result that he returned to studies in mineralogy. Aminoff's thesis for his doctorate, a crystallographic treatise on calcite and barytes from Långbanshyttan, appeared in 1918, and in the same year he was appointed lecturer in mineralogy and crystallography in the University of Stockholm.

In 1918 the Mineralogical Institute of the University of Stockholm acquired equipment for the X-ray investigations of crystals, and Aminoff was the first to use this apparatus, thus introducing X-ray methods into Sweden. At first he studied several simple structures, and among them found the first representatives for the *C* 6 (brucite and pyrochroite) and *B* 8 (nickel arsenide) types. His very extensive studies over a period of several decades of the minerals from Långban also included much X-ray work.

In 1923 Aminoff was appointed a professor and head of the Mineralogical Department of the Museum of Natural History in Stockholm. After he had obtained adequate laboratory equipment in the Museum, he could take up his research work in the new surroundings. The Långban minerals occupied much of his time, but he also devoted himself to general problems, for example, the mechanism of evaporation and dissolution of crystals. His theoretical study of the contact zone between the two individuals of a twinned crystal is of great value. Aminoff also made use of electron diffraction, as, for example, in his study of the oxidation of zinc sulphide crystals. In this case the known properties of the oxide and sulphide lattices explained the observed relative orientations of the two lattices, but could not explain the non-appearance of some orientations. In the studies last mentioned, as in much other work, Aminoff was assisted by his wife, Birgit Broomé-Aminoff.

In later years Aminoff was very interested in geochemical problems and made use of X-ray spectroscopy for his analytical work. He also spent much time trying to improve the technique of this method. Some of his latest papers (see, for example, *Nature*, April 20, 1946, p. 517) contained descriptions of his efforts to obtain large dispersion by using ground instead of natural crystal faces.

Aminoff was a born investigator who carried on his research for the sake of science. He was a very modest man of retiring disposition. This, together with the non-educational character of his institution, isolated him rather from the wider circles of Swedish science. But he never felt happier than when a friend dropped in at his laboratory with whom he could discuss his research problems.

G. HÄGG

Prof. Fred Vlès

FRED VLÈS, zoologist and biophysicist, professor in the Faculty of Medicine at Strasbourg, died on July 2, 1944, at the age of fifty-nine; he was one of a convoy of 2,500 political prisoners, taken by train from Compiègne to Dachau, of whom only 1,500 arrived alive. He had been arrested by the Gestapo at Clermont-Ferrand, where the University of Strasbourg had been evacuated. When warned that the German police were looking for him, he refused to hide for fear of possible reprisals on his colleagues.

Vlès had been a pupil of Yves Delage and was *préparateur* at the Roscoff Marine Biological Station during 1905–14. During the First World War he served in the Zouaves and was twice mentioned in dispatches. His only son, Claude, was killed in the Second World War, in the French aviation service. Vlès was a biologist with wide and original interests. He started as a zoologist, became more and more attracted to the physical chemistry of the cell, and eventually applied his knowledge to problems of human pathology. In 1921 he founded the *Archives de Physique Biologique*, and edited this journal until his death. He was one of the first to make use of cinematography in microscopy, in an investigation of the cleavage of the sea urchin egg in 1911.

Many of Vlès' researches were in the field of spectroscopy, and through this I came to know him and appreciate his human and scientific qualities when working in his laboratory at Strasbourg on the spectroscopy of chlorocruorin. Vlès was very much *le maître* to his pupils, who had an immense admiration and affection for him. He made for himself a special place in French biology which will be difficult to fill.

H. MUNRO FOX

WE regret to announce the following deaths:

Dr. I. Seymour A. Hadwen, formerly director of pathology and bacteriology at the Ontario Research Foundation, known for his work on animal pathology.

Prof. H. S. Jennings, emeritus professor of zoology in Johns Hopkins University.

Dr. S. A. Monckton Copeman, F.R.S., an authority on vaccination, on April 11, aged eighty-five.

NEWS and VIEWS

Dr. Robert Broom, F.R.S.

The election of Dr. Robert Broom as an honorary fellow of the Royal Society of South Africa is a recognition of a long life devoted to scientific work. As a student of medicine in Glasgow, Dr. Broom became fascinated by the problem of the ancestry of mammals, and on qualification migrated to New South Wales in order to work on the comparative anatomy and embryology of monotremes and marsupials while earning his living as a general practitioner. The Australian scientific world discovered his existence when a paper on the Organ of Jacobson arrived at the Linnean Society from an unknown man in the bush, to be followed by others. But during a visit to England, Broom saw some of the fossil reptiles recently brought from South Africa by Prof. H. G. Seeley, and realizing immediately that they presented a novel and direct approach to his problem of mammalian ancestry, sailed for South Africa instead of returning to Australia. There in a very few years he revolutionized our knowledge of the fossil reptiles of the Karroo, showed in broad outline how they were related to one another, and introduced a zonal subdivision of the rocks in which they were found which has proved to be applicable in Russia and China as in Central Africa. In 1910 Broom visited New York and there discovered that the Pelycosaurs from the Texan Permian were closely related to the Deinocephalia, the most primitive group of the African mammal-like reptiles. His paper on this subject established this point once for all, and has ever since formed a point of departure from which all more recent work on the classification and evolution of reptiles has proceeded.

This early work of Broom's is remarkable because in it he used his fossils for the solution of specific problems of morphology, and thus introduced a new point of view into vertebrate palæontology. But while actively working on Karroo fossils and for the greater part of his life remaining in medical practice, Broom found time to investigate the poor fragments of fossil mammals found in Pleistocene deposits in South Africa, describing many of them and showing that an extinct Quaternary fauna had existed in that land. When Prof. R. A. Dart discovered the skull of *Australopithecus*, Broom began an examination of the numerous 'bone caves' which exist in South Africa and soon found two new genera of allied giant apes. His view on the significance of these forms is fully set out in a recently published monograph (see *Nature*, June 29, 1946, p. 863), in which he shows that the three form a special sub-family of giant apes, differing in very many ways from those which still live, and that in all these ways they resemble man. They are, in fact, the most man-like in structure of all the primates; and there is some indication that, unlike the forest-dwelling gorillas and orangs, they lived in a dry country not unlike South Africa to-day. The latest discovery is described by Dr. Broom on p. 602 of this issue. This work is the most important contribution to the problem of human ancestry published for many years, and is a fitting climax to Dr. Broom's fifty years work.

Boyle Medal of the Royal Dublin Society: Prof. J. H. J. Poole

The Council of the Royal Dublin Society, on the recommendation of its Committee of Science, has awarded the Society's Boyle Medal to Prof. J. H. J. Poole, professor of geophysics in the University of Dublin, for his distinguished contributions to geophysics, many of which have been published in the Society's *Proceedings*. His early work, much of it in conjunction with the late Prof. J. Joly, was largely concerned with the measurement of the radioactivity of the earth's crust. His more recent papers include discussions of the earth's thermal history, the evolution of the atmosphere, and the possibility of initiating thermo-nuclear reactions under terrestrial conditions.

Building Research Division, National Research Council, Canada

Prof. R. F. Legget, associate professor of civil engineering, municipal and structural division, University of Toronto, has been appointed head of the Division of Building Research under the National Research Council, Canada. The new Division of Building Research will work very closely with the Central Mortgage and Housing Corporation, and will provide the required scientific data for an adequate programme in all fields of construction, including building materials, types of construction, lay-out, and all other essential features. Prof. Legget had extensive experience in construction engineering in Great Britain and on the Continent before going to Canada in 1929 to join the Construction Division of the Power Corporation of Canada. He later became a member of the staff of the University of Toronto. Born in Liverpool in 1904, he was trained at the University of Liverpool.

Marconi Jubilee and Exhibition

Fifty years ago, in 1897, Signor Guglielmo Marconi gave the first demonstration of wireless telegraphy which was recognized by the Postmaster-General as establishing a new means of communication. At that time, Marconi was twenty-three years old, and he had come to Great Britain in the previous year from Bologna, where he had conceived the idea of using the so-called Hertzian waves for the development of a means of signalling without a wire connexion between the sending and receiving stations. Sir William Preece, who was the engineer-in-chief of the Post Office at the time, had been conducting experiments with a wireless circuit using magnetic induction between large loops; and it was due to Preece's interest and encouragement that Marconi was able to develop his experiments, leading to a successful demonstration across the Bristol Channel. It was in commemoration of this demonstration that a jubilee dinner was held at Guildhall on April 21 under the presidency of Lord Listowel, the retiring Postmaster-General.

In further celebration of these achievements of fifty years ago, the Marconi Company arranged a Jubilee Exhibition at Queen's House, Kingsway London, during April 23–May 2. The Company was originally formed as the Wireless Telegraph and Signa Company soon after the demonstration mentioned above. A few years later, this became Marconi's Wireless Telegraph Co., Ltd., and, with the associated Marconi International Marine Communication Co. Ltd., has recently been incorporated in the English Electric Group of Companies. The exhibition comprised a photographic and pictorial display together with a collection of apparatus and equipment developed for various applications; this collection ranged from a replica of Marconi's original transmitter as used in 1897 to the marine type of rotating radar aerial with P.P.I. display which is being fitted to merchant ships to-day. Special attention was also given to the modern applications of radio waves, including high-speed communication and printing equipment, direction-finding apparatus, and mobile telegraph and telephone equipment for police and other purposes. In view of the present widespread use of radio waves for communication, broadcasting, television, navigational aids, surgical and industrial purposes, it is interesting to have this reminder that the whole of the technique in these fields has been developed during the past fifty years.

Amalgamation of the Institutions of Mechanical Engineers and Automobile Engineers

An important and heartening announcement is that of the amalgamation of the Institution of Mechanical Engineers and of the Institution of Automobile Engineers, which took place on April 13. During the past fifty years and more, the individual energies of engineers have been dissipated and their corporate authority has been lessened by the multiplicity of engineering institutions which grew up to satisfy the needs of specialist branches of the profession. Though many of these younger institutions have done excellent work in furthering the development of particular sections of engineering, which it was felt at the time of their foundation were neglected by the senior institutions, there is no doubt that the engineering profession has been split by conflicting allegiances; and that it has been more difficult for engineers to speak with one voice on important issues. The Institution of Mechanical Engineers was founded in 1847, so that the amalgamation occurs most happily in the year that the Institution celebrates its centenary. The Institution of Automobile Engineers is forty-one years old.

Under the terms of the agreement to amalgamate, the Institution of Automobile Engineers will surrender its charter and dissolve the Institution. Its corporate members will become corporate members of the Institution of Mechanical Engineers, being placed as the first members on the register of a newly formed Automobile Division. Whatever the advantages of the welding together of the combined membership—and they are great—it has clearly been made possible only by the generous and broad view taken, in the first place, by those holding office in the Institutions. The amalgamation augurs well for the future of mechanical engineering, and it is to be hoped that other institutions will not be slow to follow the example.

Jubilee of the Electron

April 30 marked the fiftieth anniversary of the announcement by J. J. Thomson, at an evening discourse at the Royal Institution, of the existence of the electron, and the first approximate estimate of its mass. Cathode rays had been extensively studied in many laboratories for the previous fifteen or twenty years, and their peculiar properties had been widely discussed. It was Thomson's genius which enabled him to unravel the confusing and almost contradictory clues which the experiments afforded as to the nature of the phenomenon, to grasp what was important and what was secondary in the evidence, and to make the final experiment which demonstrated beyond all reasonable doubt that the cathode rays consisted of negatively charged particles, all alike, and all much smaller than the smallest particle hitherto known to science, the atom of hydrogen. The Institute of Physics and the Physical Society, in collaboration with the Institution of Electrical Engineers, is arranging to mark this jubilee by a series of lectures and other functions in London on September 25–26 next; an exhibition demonstrating the great influence this discovery in pure physics has had on the life of the community will be opened at the Science Museum, London, on September 26 and will remain open for about three months.

Heredity

The importance of an international forum of publication in science is not likely to be underestimated by readers of *Nature*. In many branches of science the responsibility was undertaken before the War by journals published in Germany and, to a less extent, in Italy and Japan. Their sudden removal by war was not so seriously felt at the time, owing to the temporary reduction of fundamental research, but it has now raised a serious problem. The position of genetics in this regard is a special one. This science is not only rapidly advancing but it is also rapidly broadening its scope. Indeed it is beginning to cover every aspect of biology and every form of life. It is beginning to weave the threads of many different sciences and techniques into a single pattern. Darwinism and biometry, Mendelism and cytology are being joined together, and the needs of medicine and agriculture are being met by the establishment of a single fundamental discipline. But the work that is necessary to accomplish this task is scattered over the whole world and is developing different characters in different countries.

In these circumstances an explicitly international journal of genetics is bound to serve a useful purpose. Dr. C. D. Darlington and Prof. R. A. Fisher are founding such a journal in collaboration with a group of distinguished foreign geneticists. It will be known as *Heredity* and will be published by Messrs. Oliver and Boyd. The articles promised for the first volume (of which Part 1 is now due to appear) include contributions from a dozen different countries. They cover, if not the whole range of genetics, at least a large part of it. Of outstanding interest perhaps is a bibliography of genetics articles published in Germany and Italy during the War and a summary of British work for the same period. The development of this journal will be watched with keen interest throughout the scientific world.

Whitworth Scholarship Regulations

New regulations for the Whitworth Scholarships which the Minister of Education will offer for competition in 1948 have been published (H.M. Stationery Office. 3*d*. net). The following awards will be available: two Whitworth Senior Scholarships, tenable for two years, valued at £325 each; five Whitworth Scholarships, tenable for three years, minimum value £200 each; ten prizes valued at £20 each, to unsuccessful competitors for Whitworth scholarships whose work deserves recognition, the money to be spent in the furtherance of the competitor's engineering education. The conditions governing the Whitworth Scholarships have now been altered in two main respects. Candidates must have completed twenty-four months of works training instead of thirty months as hitherto, and entry is still limited to part-time students. The Ministry of Education Science Scholarships examinations in engineering will continue to be used for the purpose of making the awards, but the conditions for these have also been amended. Candidates will be required to reach a certain minimum standard in the two qualifying papers of mathematics and applied mechanics, and will also be required to take three scholarship papers, chosen from a number of alternatives. Workshop technology is introduced for the first time as one of these subjects. The entries for the Whitworth Senior Scholarships have, in the past, been governed by the same conditions as for the Whitworth Scholarships. Many university students could not qualify, however, because of the practical training conditions; this requirement has now been omitted, but a successful candidate will have to spend at least one year in a works on taking up a Senior Scholarship. No formal examination will be held, but a candidate must submit a thesis on one of a number of specified subjects.

Collection of Czechoslovak Chemical Communications

FOUNDED in 1929 for the purpose of publishing in French or English the results of researches conducted by Czechoslovak chemists, the *Collection of Czechoslovak Chemical Communications*, which ceased publication in 1939, has now been resumed under the same editorial direction of Profs. J. Heyrovský and E. Votoček. The first issue for 1947 contains an appreciation of the scientific work of Prof. Antonín Šimek, who was executed by the Germans during the War (see *Nature*, 152, 69; 1943). About half this issue is taken up with the recent polarographic researches of Heyrovský and his co-workers, who have studied certain phenomena at the dropping (and streaming) mercury cathode both polarographically and oscillographically. These open up an important new field in the study of electrode interfaces. From the laboratory of Prof. Votoček there is a paper on the synthesis of the remaining mono-methyl-azulene. The authors, F. Šorm and J. Fajkoš, started with *cis*- and *trans*-cyclopentane-dipropionic-(1, 2)-acids, and by a series of interesting steps arrived at the trinitrobenzene compound of 6-methyl-azulene. This was decomposed chromatographically over an aluminium hydroxide column. Finally, methyl-azulene was crystallized as a purple-blue solid, m.p. 83° C. Another contribution to organic chemistry is by Dr. R. Lukeš, who describes N-methyl-1.2.5.6.-tetrahydropyridine. The subscription for the journal has been raised to £2 or 400 Czechoslovak crowns.

Royal Institute of Chemistry: Anniversary Meeting

THE sixty-ninth annual general meeting of the Royal Institute of Chemistry was held on April 18. In presenting the report of the Council for 1946, the president, Mr. G. Roche Lynch, referred to some of the principal developments in the work of the Institute. Closer contact with the four Dominion chemical institutes had been established through a meeting with their representatives which was held in London last June. The first edition of a "Directory of Independent Consultants in Chemistry and Related Subjects" was issued during the year. Highly successful courses in "Oils and Fats" and "Spectroscopy", arranged at the University of Liverpool by the Liverpool and North Western Section of the Institute, represented the first of the series of courses, conferences and symposia to be held under the auspices of the Institute as such. Through the generosity of Dr. David Spence, a series of Henderson Memorial Lectures had been established as a tribute to the memory of the late Prof. G. G. Henderson, a past president of the Institute; and the first lecture in this series was delivered by Sir Ian Heilbron. By agreement between the Ministry of Education and the Institute, the scheme for national certificates has been amended so as to provide separate certificates in chemistry and in applied chemistry. During 1946, the membership of the Institute (fellows and associates) passed the 10,000 mark. Mr. G. Roche Lynch was elected president for 1947–48.

"Specpure" and "H.S." Elements and Chemicals

CERTAIN metals and chemicals of the very highest purity for spectrographic work were first supplied on a small scale by Messrs. Adam Hilger, Ltd., in 1923, and their "H.S." and "Specpure" chemicals are now well known. With increased demand for more substances and greater quantities, it has been found desirable to transfer the preparation of these carefully standardized substances to Messrs. Johnson, Matthey and Co. The range of available chemicals, to be marketed as "H.S.", "Specpure" or "Matthey" standards, has been considerably extended; some sixty-eight elements are listed, either as metals, oxides or salts, in Johnson and Matthey's latest catalogue. They are all of the highest possible purity, and their manufacture is controlled spectrographically.

International Geological Congress, 1948

THE 18th Session of the International Geological Congress, originally planned for 1940 and postponed on the outbreak of war, is to be held in Great Britain in 1948, on the invitation of the Geological Society of London. A third circular containing preliminary arrangements for the session has been issued. Meetings will take place in London during August 25–September 1, 1948, and the following subjects have been provisionally listed for discussion: (1) Problems of Geochemistry; (2) Metasomatic Processes in Metamorphism; (3) Rhythm in Sedimentation; (4) Geological Results of Applied Geophysics; (5) Geology of Iron-Ore Deposits; (6) Geology of Petroleum; (7) Geology, Paragenesis and Reserves of the Ores of Lead and Zinc; (8) Geology of Sea and Ocean Floors; (9) Pliocene–Pleistocene Boundary; (10) Faunal and Floral Facies and Zonal Correlation; (11) Correlation of Continental Vertebrate-bearing Rocks; (12) Earth Movements and Organic Evolution. Geological excursions covering most of the British Isles, which are planned to take place between August 7 and September 18, form part of the Congress programme. They include sixteen long excursions (7–16 days) before the meetings in London, and sixteen of similar length after the meetings. There will also be daily excursions, centred on London between August 22 and September 3. Sir Thomas Holland is president of the General Organising Committee and president-designate of the Congress. The general secretaries are Mr. A. J. Butler and Dr. L Hawkes, and the treasurer is Mr. F. N. Ashcroft. All communications should be addressed to the Genera Secretaries, XVIII Session International Geologica Congress, Geological Survey and Museum, Exhibitio Road, London, S.W.7.

Summer School in Inorganic Micro-Chemistry

Although the advantages of small-scale methods of analysis have led to provision in various British universities and technical colleges for a certain amount of instruction in micro-techniques, it is believed that refresher courses for chemists who have not had recent contact with micro-methods would be of value (see also *Nature*, 156, 588; 1945). Modern micro-methods are essential for attacking certain analytical problems, and in addition selected semi-micro and micro-methods offer advantages over more conventional methods in the teaching of practical chemistry to undergraduates. To provide practical experience in modern small-scale techniques, a summer school has been arranged at Queen's University, Belfast, during June 23–July 5. This course is planned to provide about seventy-five hours practical work. Particulars can be obtained from the secretary of the University.

Summer Course on Rheology

A short summer course on rheology will be given at the Polytechnic, Regent Street, London, W.1, during July 28–31. It is specially designed for those engaged on rheological problems in industry, and the lectures will deal with general rheology, as well as with certain special applications. The lecturers will include Dr. G. W. Scott Blair and Dr. L. R. G. Treloar. Particulars may be obtained from Dr. J. Topping, Polytechnic, Regent Street, London, W.1.

Place of Universities in the Community

The Division for Social and International Relations of Science of the British Association has arranged a conference on "The Place of Universities in the Community", to be held in the University of Manchester on May 10. The speakers will include: Lord Simon of Wythenshawe, Sir Henry Dale, Prof. J. D. Bernal, Prof. P. M. S. Blackett and Prof. M. Polanyi. Opportunity will be provided for other contributions to the discussion. Admission will be free, without tickets. Further particulars can be obtained from the secretary of the British Association.

Travelling Atomic Energy Exhibition

A travelling train exhibition is being organised by the Atomic Scientists' Association with the co-operation of the Ministry of Supply to illustrate the facts about atomic energy and its industrial applications in a simple and attractive manner. The train will visit fifty-five of the principal towns of Great Britain and take a year to complete the course. The information will be conveyed by charts, diagrams and photographs. It is also planned to show some simple experiments as well. At the various stopping places it is hoped to organise 'Atomic Weeks', which will include public discussions, in order to focus attention on the significance of the industrial revolution which will be brought about by the harnessing of atomic energy.

Comets

Comet Grigg–Skjellerup (1947*a*). E. L. Johnson, Johannesburg, recovered this comet on March 11, about 2° from the place predicted by F. R. Cripps in the "Handbook of the British Astronomical Association, 1947". Its magnitude was 11, but it will be a little brighter in May. An ephemeris is given below.

1947	0h R.A.	Dec.	r	ρ	Mag.
May 7	22h 38·1m	+17° 20′			
15	24·5	21 29	0·948	0·357	10·1
23	16·6	24 29			
31	10·4	+26 47	1·071	0·467	11·2

Two other comets have been discovered but are faint objects. Ephemerides are given for the month of May.

Comet Jones (1946*h*).

Announcements

Prof. P. M. S. Blackett, Langworthy professor of physics in the University of Manchester, will deliver a lecture on "The Magnetic Field of Massive Rotating Bodies" at a meeting of the Royal Society on May 15 at 4.30 p.m.

Prof. E. D. Adrian, professor of physiology in the University of Cambridge, will deliver the Alexander Pedler Lecture under the auspices of the British Association on May 14 at 5.30 p.m. The Lecture will be given in the Royal Institution, and Prof. Adrian will speak on "The Sense of Smell". Tickets are available on application to the secretary of the British Association.

In connexion with the Pasteur Exhibition at the Science Museum, two public lectures will be given in the lecture theatre of the Museum on Pasteur and his work: Prof. J. D. Bernal will speak on "Pasteur, the Crystallographer" on May 14 at 5 p.m.; Dr. E. Chain on "Pasteur, the Biochemist" on May 19, also at 5 p.m.

Messrs. Kodak Ltd., Wealdstone, Harrow, Middlesex, have arranged an exhibition of applied photography to be held at Australia House, Strand, London, during May 7–16, 10 a.m.–5.30 p.m. (except May 10 and 11). The exhibition will be opened by Prof. E. N. da C. Andrade on May 6 at 11 a.m.

Dr. F. D. Ommanney has been appointed by the Colonial Office to be marine biologist, Mauritius–Seychelles Fishery Survey.

The Twelfth International Congress of Psychology, postponed from 1940, will be held in Edinburgh during July 23–29, 1948. Prof. James Drever is president of the Committee of Organisation, and Prof. Godfrey Thomson, Moray House, Edinburgh, 8, is general secretary. It will facilitate arrangements if those likely to attend will communicate with the general secretary.

At the annual general meeting of the Gas Research Board, Viscount Falmouth was re-elected president for 1947–48, and Dr. Harold Hollings, controller of research of the Gas Light and Coke Co., has been appointed chairman in succession to Dr. E. V. Evans, who has resigned.

Erratum. In the communication "Plasma Cellular Reaction and its Relation to the Formation of Antibodies *in vitro*" in *Nature* of April 12, p. 499, the abbreviation 'pcs' used by the author in the heading of col. 6 of Table 1 was wrongly interpreted as 'plasma cells'; it should read 'pieces'.

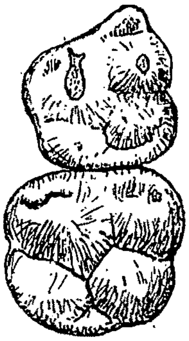
The Upper Milk Molars of the Ape-man, *Plesianthropus*

A FEW days ago I discovered at Sterkfontein remains of two new skulls of *Plesianthropus transvaalensis*. The specimens were found within a few feet of the spot where the type was discovered. One of the specimens is the crushed snout of apparently a young male with some beautiful teeth. The other is a fragment of the snout of a young child of about three years. This latter specimen has the milk molars shown in almost perfect condition.

Comparatively little study has been made of the milk molars of the different races of man; little on the milk molars of the living apes, and scarcely anything is known of the milk molars of the fossil apes.



LEFT MILK UPPER 1ST AND 2ND PREMOLARS OF *Plesianthropus transvaalensis* BROOM. TWICE NATURAL SIZE

The accompanying figure shows the two upper milk molars of *Plesianthropus*. If these be compared with figures I have given in the book on "The South African Fossil Ape-men" of the corresponding teeth in the Taungs ape-man *Australopithecus* and in a Bush-child, it will be seen that there is fairly close agreement. In fact, the teeth are practically identical in structure with those of the Bush-child.

In the 1st milk premolar, attention may be directed to the well-developed anterior outer accessory cusp, which is practically a human character, and to the presence of a Carabelli pit on the anterior inner main cusp.

In the 2nd milk molar there is not only a well-marked Carabelli groove, but also a well-developed Carabelli cusp. In the Bush-child tooth which I figured there is also a well-marked Carabelli cusp.

The Carabelli cusps on the inner and anterior side of the inner and anterior main cusp is a human character rarely, if ever, seen in apes, though what may be the homologue occurs in some lemurs; and the cingulum seen in *Proconsul* and some other early apes may be the factor that determines the Carabelli cusp.

The presence of a distinct Carabelli cusp on the 2nd milk premolar of *Plesianthropus* seems to show that this ape-man is very nearly related to man, and not closely related to the living apes.

Normal Development of Fertilized Rabbit Ova Stored at Low Temperature for Several Days

WE are indebted to Ivanov[1,2], Walton[3,4], and Hammond[5] for the demonstration that mammalian spermatozoa can be kept at low temperature for some length of time without loss of fertilizing capacity. These observations gave rise to the new technique of artificial insemination in animal breeding, which is widely practised for live-stock improvement.

The viability of rabbit spermatozoa in the female tract following copulation[6] is only about 30 hours. However, rabbit spermatozoa can be kept alive *in vitro* for 96 hours at 10° C.[5], or 168 hours at 15° C.[4]. At body temperature, the maximum survival time *in vitro* is 13 hours[4]. Rabbit ova are capable of fertilization only for 6–9 hours[7,8] after ovulation *in vivo*.

In view of the fact that the life-span of spermatozoa is shorter at body temperature *in vivo* or *in vitro* than at low temperature *in vitro*, and in view of the fact that the delayed implantation of fertilized ova is fairly common in certain mammals (for example, Mustelidæ and Muridæ[9]), it was thought possible that the fertilized ovum could be kept *in vitro* at low temperature for a certain length of time without loss of its capacity for normal development.

Ova of super-ovulated rabbits[10] in the two-blastomere stage were stored in pure rabbit serum at low temperatures for varying lengths of time and then cultured for 24 hours at 37° C. to determine whether normal cleavage would occur. It was found that rapid cooling from 25° to 0° C., or to 5° C., followed by maintenance for 24 hours at the low temperature, was harmful to the subsequent viability of ova. On the other hand, slow cooling (from 25° to 0° C. in 5 hours, or from 25° to 5° C. in 4 hours) was considerably less harmful. However, there is no difference between rapid cooling and slow cooling from 25° to 10° C. These results indicate that the ova are subject to temperature shock upon rapid cooling, but can be acclimatized to lower temperatures by slow cooling. The latter procedure has been demonstrated by Chang and Walton on spermatozoa[11].

The optimal temperature for the survival of ova was found to be 10° C. (see table).

THE VIABILITY OF FERTILIZED RABBIT OVA CULTURED AT 37° C. AFTER PRE-INCUBATION AT LOWER TEMPERATURES

Storage time (hours)	Storage temperature (° C.)	Per cent normal cleavage
24	0	63·4
	5	78·3
	10	82·2
	15	85·5
	25	37·2
72	0	48·1
	5	54·2
	10	58·8
	15	43·1
	25	0
120	0	0
	5	6·3
	10	36·5
	15	0
144	10	23·6
168	10	0

The normal cleaved ova cultured at 37° C. following low-temperature storage were transplanted[8] into the Fallopian tubes of doe rabbits, which had been injected with gonadotrophin 24 hours earlier to induce ovulation. In each instance, 4–15 ova were transplanted to each rabbit. After transplantation of ova stored at 0° C. for 78–102 hours, four litters of one to two young each were delivered. Four litters (2–7 young) were delivered from eight recipient does following transplantation of ova stored at 5° C. for 48–80 hours. Four litters of one to four young were delivered from five recipient does after transplantation of ova stored at 10° C. for 80–101 hours. One litter of one young was obtained from two recipient does after transplantation of ova stored at 15° C. for 72 and 96 hours. All the young born were healthy, normal and genetically true to their real parents.

Finally, five does were transplanted with normal cleaved ova cultured at 37° C. for 24 hours after storage at 10° or at 5° C. for 120–144 hours; one of them gave birth to an abnormally small young at full term. Considering the small litter size in the cases of successful transplantation and the failure of pregnancy after longer times of ova storage, it is evident that the ova which cleave normally in culture are not necessarily sufficiently viable for full development.

This work is still being carried on to determine the efficacy of transplantation, and the detailed results will be published elsewhere. Considering the improbability of multiple birth after super-ovulation[12-21], and the possibility of application of the technique in animal breeding, these findings may open a new field for the full utilization of the germ cells of valuable animals.

The work was carried out in the laboratory of Dr. Gregory Pincus, to whom I am much indebted for advice and encouragement. Thanks are due to the Foundation for Applied Research, San Antonio, Texas, U.S.A., for a grant.

Hyaluronidase in Sea-Urchin Sperm

A SUBSTANCE liquefying the jelly-coat of sea-urchin eggs was first recovered from the sperm of sea-urchins by Hartmann and Schartau[1], who called it 'Androgamone II'. The enzyme nature of this substance was, however, denied[2]; moreover, it was pointed out that hyaluronidase from bull testis does not dissolve the jelly-coat of sea-urchin eggs[3]. On the other hand, an enzyme preparation from *Clostridium oed. mal.* was found to dissolve it[4].

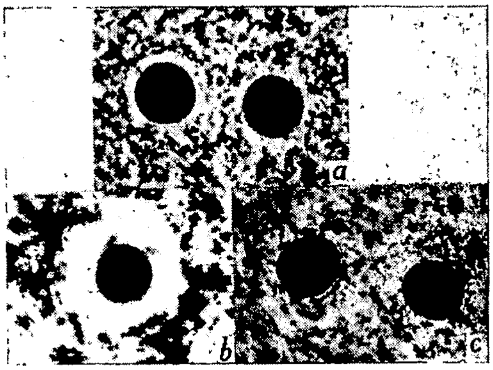

Fig. 1. EGGS OF *Sphærechinus gran.* IN INDIAN INK, IN ORDER TO MAKE THE JELLY-COAT VISIBLE: (*a*) NORMAL EGGS; (*b*) AFTER 3 MIN. ACTION OF A PREPARATION FROM *Arbacia* SPERM; (*c*) AFTER 13 MIN. THE JELLY-COAT IS COMPLETELY DISSOLVED

Recently, McClean and Rowlands[5], Fekete and Duran Reynals[6] and Rowlands[7] stated that hyaluronidase from the sperm of some animals (and from other sources, too) disperses the cumulus cells of mice and rat eggs. We therefore tried to find out whether the liquefying factor from the sea-urchin could be identified with hyaluronidase.

From sperm and testes of *Arbacia lixula* (= *pustulosa* Auct.) and *Sphærechinus gran.*, a substance was obtained which dissolves the jelly-coat of sea-urchin eggs and also lowers the viscosity of a mucin solution.

The preparation was made according to the technique of Claude and Duran Reynals[8]; that is, by extracting the ground material with $N/10$ acetic acid and precipitating with acetone. The precipitate was desiccated *in vacuo*. From 100 gm. of fresh material, 1 gm. of powder was recovered. This powder was dissolved in sea-water (pH *c.* 8) or in 0·85 per cent sodium chloride (pH *c.* 6·8). About 60 per cent of the powder remained undissolved and was removed by centrifuging. The ability of the solution (15 mgm. dry matter in 10 c.c. of solvent) to dissolve the jelly-coat of unfertilized sea-urchin eggs and to lower the viscosity of a mucin solution (in 0·85 per cent sodium chloride, pH *c.* 7) was tested. As a control, a preparation from bull testis and a total extract from heads of leeches was used.

The jelly-coat of unfertilized sea-urchin eggs (*Psammechinus*, *Sphærechinus*, *Arbacia*, *Paracentrotus*) swells as soon as the eggs are placed in the solution (Fig. 1 *b*), and after 10–15 min. it is completely dissolved (Fig. 1 *c*). A similar effect is shown by the extracts from heads of leeches. Preparations from bull testis, on the other hand, fail to dissolve the

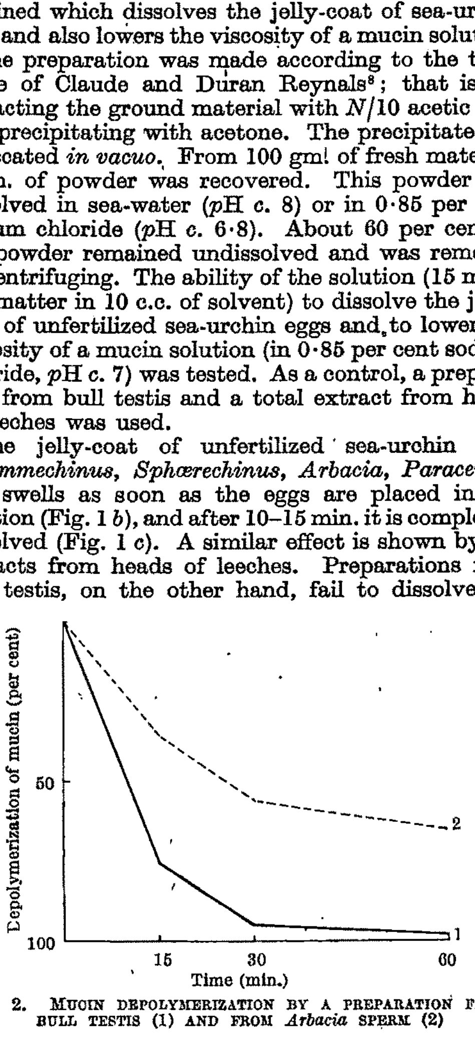

Fig. 2. MUCIN DEPOLYMERIZATION BY A PREPARATION FROM BULL TESTIS (1) AND FROM *Arbacia* SPERM (2)

jelly-coat, which swells only after one hour of incubation. The two preparations also act in different ways when tested on a mucin solution: that from bull testis lowers the viscosity strongly and quickly, whereas that derived from sea-urchin testis acts only very slowly (Fig. 2).

Dialysis and egg water do not inactivate our preparation. Tryptic activity was excluded. The power of the preparation to liquefy the jelly-coat and to depolymerize the mucin disappears on heating at 100° C. for 5 min.

A more detailed account and a discussion of these results will be given elsewhere[9].

Mutations in *Drosophila* Induced by a Carcinogen

Numerous attempts have been made by several geneticists to induce mutations in *Drosophila* by treating either eggs, larvæ, pupæ or adults with various chemicals. The first unquestionably positive results were obtained by C. Auerbach and J. M. Robson, who induced genetic changes in the sperm of males by exposure to the vapours of various mustards. There is very little doubt that the method of treatment developed by Auerbach and Robson contributed significantly to their success. This method can be used with chemical substances that can be handled as vapours.

For almost two years I have been working on a method that permits the use of chemical substances in solution. *Drosophila* males are kept in an atmosphere containing a fine ærosol of the solution being tested for mutagenic capacity. So far twenty-one substances have been investigated. An aqueous ærosol of nitrogen mustard (*HN*2) was the first to give positive results[1], indicating that the method is effective. Experiments are now in progress to test the mutagenic potency of several carcinogens, applied as ærosols of oil solutions. The first to be used was 1,2,5,6-dibenzanthracene. It gave positive results. Sperm of treated males was tested for X-chromosome lethals by the standard *ClB* method, and a considerable increase in the proportion of lethal mutations was observed.

	Chromosomes tested	Lethals	Per cent
Controls	7,755	3	0·04
Tests of 19 substances	47,028	18	0·04
Nitrogen mustard	5,491	90	1·67
1,2,5,6-dibenzanthracene	3,257	29	0·89

All lethals obtained in these experiments are being tested for chromosomal aberrations. The first results indicate that dibenzanthracene induces breaks in chromosomes as well as mutations.

Experiments with several carcinogens are now in progress, to determine if there is any correlation between carcinogenicity and mutagenic capacity in chemicals.

Selective Mating as a Factor for Speciation in Cichlid Fish of East African Lakes

In most of the modern texts on evolution[1], one of the outstanding proofs of speciation, that is, development of forms separated from one another under normal conditions by their immiscibility, without geographical isolation, is the very high number of species and genera of the Cichlidæ in almost every one of the great lakes in East Africa. This remarkable phenomenon (Woltereck's "*schizotypische Artaufspaltung*") is characteristic only for the Cichlidæ of the East African lakes; other genera of freshwater fish can be represented in the same area also by more than one species, but in no other family is the diversity of types—some of them being specialized to a certain mode of life and nutrition—so well developed as in the Cichlidæ.

A plausible interpretation of this fact is still wanting, because the many factors influencing the rapid tempo of evolution proposed up to this time (existence of predators, small number of individuals occupying a new niche, old age of the lake basin in question, etc.) do not fit all lakes in the same manner and, on the other hand, would be applicable also for fish of other families. So there must exist, with high probability, a special mechanism in the Cichlidæ favouring a splitting-up in smaller groups with preferred mating tendencies *intra se* not found in the other groups.

The Cichlidæ show in varying degrees very characteristic breeding-habits. Where in other fish there is parental care for the brood, generally only one of the parents is involved; in the majority of the cases it is the male that is concerned with defence, aeration, etc., of the eggs and care of the young fish. In the Cichlidæ, however, there are many cases where the two parents co-operate in their care for their brood. (In some of the genera, for example, in the mouthbreeders, only one of the sexes is involved.) Normally the two sexes live in monogamy[2], at least for the time of one brood, lasting from the beginning of nesting to the end of the family life with the fry which begin an independent life only some days or weeks after hatching. It is easily understandable that, by the introduction of a type of monogamy, even if it is only for one breeding period, a factor is involved which acts against panmixia. Furthermore, it is a well-known fact, which has been observed by a great number of fish-breeders, that in the selection of the mate there is a clearly visible preference between two individuals in a larger swarm of fish of the same species of Cichlidæ. The two mates, long before egg-laying begins, choose a certain corner of the aquarium and do not allow other fish to approach it. This fact proves that pair formation is not haphazard, but conditioned by some psychological factor which results in a strengthening of a relative sexual isolation of different pairs or families from one another. At least under aquarium conditions the continuity of the monogamic life of a male with a certain female, even in the time between two breeding periods, is not an exception but the rule in certain South American Cichlidæ.

In this connexion it is interesting to note that the blind cavernicolous Cichlids of south-west Africa are of the mouth-breeding type, where only one of the two sexes is charged with the care for the brood, and not of that 'father *and* mother family' type of family care which seems to have been able to play an important part in the acceleration of species formation *in loco* in the Cichlidæ of the great East African lakes.

Feeding Mechanism of Water-Bugs

THE suggestion put forward by Walton[1] that the presence of small teeth and chitinous elevations in the pharynx of *Micronecta* indicates that this Hemipteran ingests and masticates particulate food material appears to be true for other families of the Cryptocerata. There exists in many, and probably all, species of Corixidæ a type of feeding mechanism which does not seem to have been recorded. This takes the form of a modification of the cibarial suction pump[2] in such a manner as to produce a pair of chitinous jaws having a structure and position strongly suggesting that they function as organs for the comminution of solid material. It is a mechanism more elaborate in form than that found in *Micronecta*. The whole ventral wall of the cibarial pump consists of a curved chitinous plate having a thickened posterior margin. The anterior border of this plate appears to be folded back and modified into a transverse triangular bar set with rows of minute tooth-like projections. Above this bar and articulating with it at its lateral ends lies a second chitinous bar formed by the thickened dorsal wall of the cibarium and similarly equipped with teeth or rugosities (Fig. 1). The two bars have the appearance of a pair of grinding jaws, and although the musculature of the organ has not been studied in detail, enough has been noted to support this supposition.

Some variation during the life-cycle in the importance of this mechanism for the grinding of food particles may exist, as in early instar nymphs (Fig. 2) the toothed surfaces are distinct, whereas in the imago, while the ventral plate and jaws are more heavily chitinized, the teeth appear to be less pronounced.

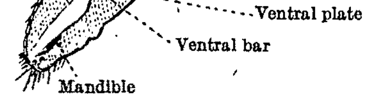

Fig. 1. DIAGRAMMATIC LONGITUDINAL SECTION OF THE HEAD OF *Sigara striata* TO SHOW DISPOSITION OF SCLERITES IN THE CIBARIAL PUMP

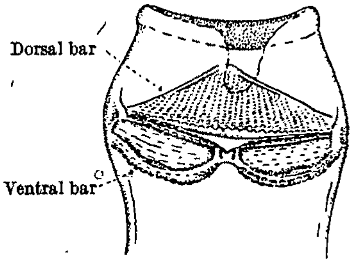

Fig. 2. DORSAL VIEW OF CIBARIAL PUMP IN NYMPH OF *Sigara striata*

The twelve species of *Corixa*, *Sigara*, *Glænocorisa* and *Cymatia* so far examined all show the structure with only minor variations in form between the species. A somewhat similar organ is present also in *Notonecta*, where, however, the teeth are replaced by bristle-like projections; in this family it may serve as a filter.

This is thought to be a type of food ingestion unique in the Hemiptera, and further investigation of the mouth parts and feeding in Corixidæ and Notonectidæ is being made for publication at a later date.

Effects of High Temperature and Short Days on Vernalization Response of Summer Varieties of Rice

THE effect of high temperature on the acceleration of flowering in a number of varieties of rice has been reported previously[1,2,3,4]. In addition to early flowering, pre-sowing high-temperature treatment results in better resistance to drought conditions[5]. Vernalization by high temperature has practical difficulties. Radicles and plumules emerge from the seed coat during treatment, involving difficulty of transportation. This has been overcome in two varieties of rice noted below by limiting the moisture content of seeds to 30 per cent of fresh weight. Seeds at this moisture content germinated without the radicles and plumules penetrating the seed coat, and gave vernalization response when exposed to high temperature, 35° C., for 10 and 20 days (see table).

As regards the effects of day-length on flowering, a marked contrast between summer (Aus) and winter (Aman) varieties of rice has been noted by us. In previous communications in *Nature*[6,7], acceleration of flowering of winter varieties by short days has been reported by one of us, and this has been confirmed[4]. On the other hand, the effect of short days on summer varieties is different. The following results (see table) show that short days delay flowering and annul the effect of vernalization by high temperature. Pre-sowing high-temperature treatment accelerates flowering; but when this is followed by short-day exposure of seedlings, a reverse effect in the delay in flowering is noticed.

In the light of these findings, Kar's statement[4] that in different varieties of paddy warm temperature associated with short day-length is inducive to earliness, and cold temperature or longer day-lengths produces retardation, needs modification. In the

varieties examined by us, short days did not induce earliness but rather they have a devernalizing effect; also long days do not always retard, but sometimes accelerate, flowering, for the data for two Aus varieties presented in the statement[4] show acceleration by long days. It appears to us that Kar's results indicate that in Aus varieties long days, and in Aman varieties short days, tend towards the acceleration of flowering.

We desire to thank the Indian Council of Agricultural Research, New Delhi, for a grant in aid, and the Department of Botany, University of Calcutta, for laboratory facilities to carry out the investigation.

Sunflower Stem Cultures for the Detection of Plant Hormones

FRAGMENTS of young stem tissue of *Helianthus annuus* (L.), when cultured on a nutrient medium containing 2 per cent sucrose and mineral salts, are capable of making only a limited amount of growth, chiefly confined to the production of a pad of callus tissue on the cut surface. Such cultures have been shown to respond in various ways to certain plant hormones. Root production results from the addition to the medium of one part per thousand million of such substances as indole acetic, indole butyric or naphthalene acetic acid to the agar on which such stem fragments are cultured. The type of root growth varies with the hormone used[1]. Higher concentrations of these substances cause a characteristic proliferation of the stem tissue. These reactions have already been used to demonstrate the presence of indole acetic acid in commercial penicillin. The crystalline penicillins *G* and *X* were shown to have root-initiating properties by this means, but to differ from indole acetic acid in that they failed to induce the same characteristic cellular proliferation at high concentration[2]. The reactions have also led to the detection of growth-substances in bacteria-free crown gall tissue.

The following method has been used for applying tests. Sunflower plants (var. Russian giant) were grown in pots until the first internode of the plant was fully expanded and the second was on the point of beginning to elongate. Such plants were cut off at the base and removed to the laboratory. By means of sterile forceps the epidermis was carefully stripped from the first internode, which was freed by this means of all external contaminants. The internode was then cut into segments of about 4 mm. in length by means of a sterile scalpel. Each segment was then transferred to an agar slope containing 0·8 per cent agar, 2 per cent sucrose, mineral salts (White's solution) and the substance to be tested. Tests so far have been carried out in 25 mm. × 150 mm. 'Pyrex' tubes containing 20 c.c. of agar. If the amount of material available was limited, it was incorporated into a few millilitres of agar, which was then cut into small blocks and applied to the cut surface of the stem fragment.

The sunflower stem fragments were taken from the upper half only of the internode, as tissue of the lower half tended to produce roots spontaneously. Material to be tested was always applied to the basal end of the fragment. If a root-producing substance had been added to the agar, root production was generally evident in about four days. A two-week period of growth was used when it was desired to detect the influence of a substance on the increase in fresh or dry weight of the fragment. Quantitative estimates of this kind were based on means from at least twenty samples. Histological effects of the unknown substances were also looked for.

Sex Differences in Colour Vision

IN a previous communication[1], it was shown that women with known colour-blind relatives were significantly more often red-green weak to a slight extent than women taken at random. This carried the implication that red-green blindness must be an incompletely recessive Mendelian character (although sex-linked), because a large proportion of the women with known colour-blind relatives must be heterozygous for that defect. Several later experiments have confirmed that conclusion, essentially the same results being obtained with each new group tested.

Another experiment, carried out on 191 men and 185 women with normal colour vision (but otherwise chosen at random), and 18 women with known colour-blind relatives, has confirmed the same conclusion in a different way. Sensitivities to the differences between red and green and between yellow and blue were measured by the limiting method, using monochromatic colour filters. The subjects tested were then grouped to compare men with women selected at random, and these women in turn with the women who knew of colour-blind relatives. The χ^2-technique showed a higher proportion of women than of men in the random samples, who had more than twice the modal red-green threshold, on a probability-level of less than 0·001, although the modal threshold was the same for both sexes. Similarly, there were more women with twice the modal red-green threshold among those with known colour-blind relatives than among the random sample of women, on a probability-level of less than 0·01. In yellow-blue vision there were no significant differences, either between men and women, or between women at random and women with colour-blind relatives.

If we take Vernon and Straker's figure of 7·31 per cent of red-green defectives among men in Glasgow and the west of Scotland[2], which seems to be a likely proportion compared with other estimates for their frequency among white people[3,4], we may expect about 13·57 per cent of heterozygotes for sex-linked red-green defects among the population of women for the same area. In a sample of 185 women taken at random, we should expect about 25 heterozygotes. In the sample of 185 actually observed, there were 18 more women with twice the modal red-green threshold than there were men in the sample of 191 men, and this does not differ significantly from the 25 heterozygous women expected. This confirms the reliability of the test.

Although there are more major red-green defectives in the population of men than of women, there are more women than men with slight red-green weaknesses. This confirms the view that major red-green defects are sex-linked recessive characters, but incompletely recessive, so that most of the heterozygotes show the character to a slight degree. No sex differences of either kind can be found in yellow-blue vision.

The Name 'Penicillin'

The recent note "Aspergillin: a Name Misapplied to Several Different Antibiotics", in which Tobie[1] deprecates the practice of assigning names to antibiotics without due consultation of the literature, prompts me to point out, for its historical interest, that even penicillin has not escaped such a duplication in naming. I refer to the use of the name 'penicillin' by Palei and Osuicheva[2] in 1936 to designate a thermostable substance isolated from *Penicillium luteum purpurogenum*, which was unfavourable to the production of citric acid by *Aspergillus niger*. This was seven years after the first use of the term by Fleming[3] in his now famous paper. The oversight is probably due in part to the vagaries of indexing. The name 'penicillin' did not appear in *Chemisches Zentralblatt* until 1934, or in the British abstracts until 1933; it can, however, be found in the 1929 *Chemical Abstracts* and the *Biological Abstracts* for 1930. This serves as another warning against too much reliance on a single abstracting source.

Emission of Secondary Charged Particles in Fission

It now seems fairly well established that in roughly 1 per cent of all fissions an α-particle is liberated at the moment of fission[1,2]. These secondary α-particles are mostly of small energy (< 2 MeV.), but some are found having energies greater than 20 MeV. It is obviously of interest to discuss the conditions in which such 'secondary' emission may occur.

As concerns the moment of liberation of the α-particle, the direct evidence from the tracks found in loaded emulsions is that an interval of time greater than about 3×10^{-13} sec. does not in general elapse between the instant of fission and the moment of liberation; and the fact that directions of emission at right-angles to the line of separation of the fission fragments are more probable than any others is perhaps even more cogent, though less direct, evidence that the average time interval is much smaller than this. In any case, it is clear that, for α-particles of energy less than 2 MeV. and nuclei of medium atomic number, the half-value period for normal radioactive disintegration is enormously greater than 10^{-12} sec., so that these low-energy particles at least cannot be emitted spontaneously from nuclei which have already settled down to conditions of near-spherical symmetry after the main phenomena of fission have taken place.

We have to discuss, therefore, what is in effect ternary fission, with the third fission fragment assumed to be an α-particle in all cases: and we have to attempt to answer the questions, first, why protons are not as frequently emitted in similar events and, secondly, why ternary fission with α-particle emission is relatively so rare. For almost every other case of fission can plausibly be regarded as a case of ternary (or quaternary) fission, with a 'secondary' neutron as the third (or fourth) particle involved.

One possible approach to an answer might be to assume that since neutrons are in excess in the heavy nucleus in relation to all types of binary fission, the liberation of secondary neutrons is natural, and that when in rare cases protons also become free in the process of division of the compound nucleus, they coalesce with the 'nascent' neutrons to form an α-particle. Such a point of view has the advantage of tackling both questions at once, but the disadvantage that it requires the setting free of protons in pairs.

However, I favour another approach altogether—and it takes first the question why α-emission is relatively so rare. It is assumed that this rarity is connected with the fact that natural α-radioactivity does not appear with medium-heavy elements except within very restricted ranges of Z (atomic number). At present, only one 'naturally' α-active species has been definitely identified ($^{148}_{62}\mathrm{Sm}$), but there is some evidence that ($^{145}_{61}$) may be another, and that a second narrow range of Z ($Z \sim 40$) may be found to include species which are α-unstable[3]. Also, from the practical point of view, the distinction should be made between the 'natural' α-activity of the medium-heavy elements which has remained undiscovered because the characteristic half-value period lies between, say, 10^3 and 10^8 years, or is greater than 10^{14} years or thereabouts; and that which has hitherto escaped detection because of the much more probable positron activity of a species which is 'artificially' produced. Theoretically, of course, such a distinction is of no significance, but it may well reflect one aspect of the situation explaining possible gaps in our present knowledge.

The connexion between natural α-activity and the emission of secondary α-particles in fission is regarded as follows. It is considered that fission is essentially a 'binary' process—the division of the unstable compound nucleus into two fragments—and it is further assumed that any secondary effect occurs between the instant when the two fragments are first separate and the instant when for both the initial energy of deformation has been dissipated. We may hazard a guess that this may happen within a time of the order of 10^{-20} sec. So far as the secondary neutrons are concerned, this point of view is consistent with the observed fact that the energies of the secondary neutrons are on the whole considerably greater than the energies of the so-called delayed neutrons[4,5], an effect to be expected if the former are emitted from fission fragments moving with high velocities whereas the latter are emitted from nuclei which have already been brought to rest[6].

As concerns the emission of secondary α-particles, taking this view of the matter, it is considered that the initial phase of separation of the fragments provides an opportunity for the emission of particles from deformed nuclei in a time which would be altogether too short for normal 'radioactive' disintegration. However, the conditions which must obtain to render such emission at all probable are satisfied only when the primary fission fragment is a nucleus which is α-unstable in its ground-state—or nearly so, for it must be remembered that, in the initial phase considered, the fragment nucleus is not only deformed but also endowed with considerable energy of excitation. Since it appears to be a general rule that the maximum α-instability for Z constant occurs for a small rather than a large value of A (mass number)[7], these conditions for α-emission will be seen to require modes of binary fission in which the 'excess' neutrons are shared very unevenly between the fragment nuclei. That such modes of fission must occur, however, is known from the identification of $^{82}_{35}$Br, $^{86}_{37}$Rb and $^{136}_{55}$Cs as primary fission products[8]. In the very rare modes of fission (relative probabilities 10^{-7}–10^{-4}) in which these species are produced, the disparity in respect of neutron excess in the fragments is extreme: neglecting secondary neutron emission, it would appear to be 1 : 15, 1 : 17 and 3 : 15, in the three cases in question. However, in these cases the fragment nuclei are of odd atomic number; for division into fragments of even atomic number, the total neutron excess would be considerably smaller. For fragment nuclei of charge numbers 40 (Zr) and 52 (Te) or 60 (Nd) and 32 (Ge), for example, the masses of the stable isotopes are such that a total excess of 10 neutrons, only, has to be disposed of by sharing between the fragments and by secondary emission in each case. If, therefore, we accept the narrow ranges of atomic number around $Z \sim 40$ and $Z \sim 60$ as ranges of possible α-instability, it would appear reasonable, on the basis of present knowledge of the dependence of fission yield upon mass number[8], and of the general point of view outlined above, to attribute the more abundant secondary α-particles of low energy to emission from fragment nuclei belonging to the lower range of Z ($Z \sim 40$), and the less abundant but more energetic secondary α-particles to emission from nuclei having $Z \sim 60$.

It might be remarked that since the above was written, I have noticed the announcement[9] of the release of a preliminary American report by Farwell, Segrè and Wiegand dealing with the long-range secondary α-particles. This report does not appear as yet to be available in Great Britain. A publication by Demers[10] has also come to hand.

Finally, thanks should be recorded to Messrs. Green and Livesey for their kindness in communicating their results before publication.

Spontaneous Fluctuations of Current in a Photo-Electric Cell

DATA on the fundamental electrical Brownian movement arising in a high-vacuum photo-cell appear to us to be rather scanty. In the saturated condition, on the plausible assumption that all the emitted electrons proceed to the anode randomly and independently, one might expect the familiar Schottky formula[1] to be obeyed by the current fluctuations, namely:

$$\overline{(i - I)^2} = 2eI\Delta f, \quad . \quad . \quad . \quad (1)$$

where i is the instantaneous current, I is the mean current, Δf the band-width of the measuring instrument.

B. A. Kingsbury[2] reports some measurements giving a value of $\overline{(i - I)^2}$ 25 per cent higher than the theoretical prediction. This work may well have been marred by 'flicker effect'[3,4]. W. A. Harris[5] states baldly that equation (1) will be fulfilled, without reference to experimental data.

In the space-charge limited region where only a portion of the emitted electrons reaches the anode, formula (1) will, in analogy with the well-known facts about the 'shot effect' in thermionic valves, be replaced by

$$\overline{(i - I)^2} = 2eI\Gamma^2\Delta f, \quad . \quad . \quad . \quad (2)$$

where the factor $\Gamma^2 < 1$ is usually termed the 'space-charge reduction factor'. As the space-charge reduction effect must vanish in the 'retarding field' region for very small currents, $\Gamma^2 = 1$ should hold in the latter case and in the saturation region (according to (1)), and it should have a minimum value somewhere in the space-charge region.

These predictions are verified by the results of an investigation on the shot effect in photo-electric cells which is being carried out by one of us (D. K. C. McD.). Fig. 1, representing the dependence of Γ^2 on I in the saturation region, shows clearly that $\Gamma^2 \rightarrow 1$ for the saturation condition within the limits of experimental error. Fig. 2, referring to the region of very small currents with considerable space-charge limitation, shows that Γ^2 indeed increases with decreasing current within this region, and tends towards unity for very small currents.

On the basis of measurements of the spectral response of the type of photo-cell used in these experiments, and assuming a black-body intensity

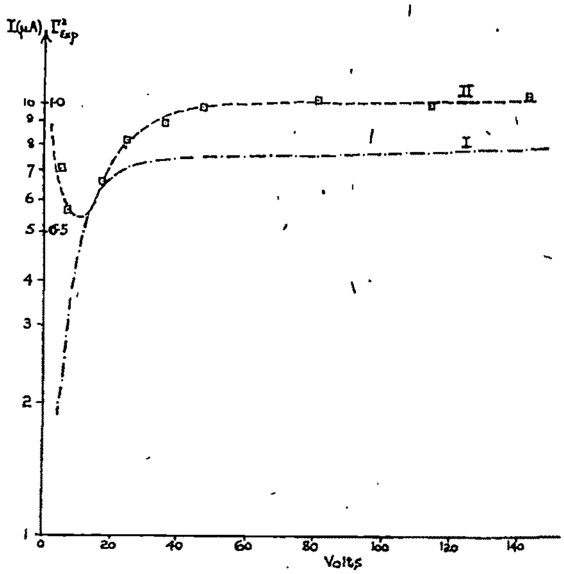

Fig. 1. CHARACTERISTIC OF THE PHOTO-CELL (CURVE I, LEFT-HAND SCALE) AND SPACE-CHARGE REDUCTION FACTOR Γ^2 OF THE SHOT EFFECT (CURVE II, RIGHT-HAND SCALE) AS A FUNCTION OF ANODE VOLTAGE

distribution in the spectrum of the illuminating incandescent lamp, one of us (R. F.) has shown that the energy distribution of the photo-electrons is roughly 'Maxwellian', corresponding to a 'temperature' of about 2,000° K., which is lower than the filament temperature of the lamp, as one might expect.

Using the theory of space-charge-reduced noise developed by D. O. North[6], the electron 'fluctuation temperature' was estimated from the experimental data for Γ^2. Extrapolation to zero current ($\Gamma^2 = 1$) gives a temperature $\sim 3,000°$ K. As this shows agreement in order of magnitude with the 'electronic temperature' estimated above from quite different observations, we may thus reasonably conclude that the usual shot effect theory is valid for the saturation and 'retarding-field' regions.

In the intermediate region, however, the apparent fluctuation temperature is found to vary, increasing with current I; hence North's theory is not directly applicable here.

The most probable explanation lies in the fact that the whole of the emitting surface is not uniformly illuminated; the behaviour will thus be analogous to that of a thermionic valve with part of the cathode at a temperature lower than the rest. Therefore, in this region the observed Γ^2 would be greater than the anticipated value; agreement with theory can thus only be expected in the two extreme regions.

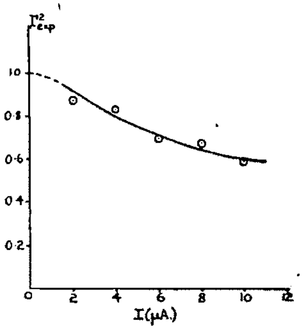

Fig. 2. SPACE-CHARGE REDUCTION FACTOR AS A FUNCTION OF CURRENT (UNDER STRONG ILLUMINATION) IN THE REGION OF EXTREME SPACE-CHARGE LIMITATION

We hope to present a fuller treatment at a future date, and one of us (D. K. C. McD.) has commenced work on measurements of fluctuations using monochromatic radiation and low temperature for the cell.

The assistance of the General Electric Co., Ltd., Wembley, in supplying the photo-cells for this investigation is gratefully acknowledged.

Identification by X-Rays of Interface Compounds on 'Oxide' Cathodes

A RECENT paper by Fineman and Eisenstein[1] has presented interesting observations concerning the interfacial films formed between coating and metal core material on alkaline earth oxide-coated cathodes. Nickel alloys containing impurity elements such as magnesium, aluminium or silicon (or like elements) are commonly employed for these cathodes, and it has been accepted for many years that the process of activation is facilitated by the presence of one or other of the above impurities[2]. Chemical reaction with the alkaline earth oxide at elevated temperatures frees barium ions which are required for the development of the thermionic emission.

The detection and identification of the interfacial reaction products, if such be formed, are of importance from several points of view. For one thing the detection of the interfacial film reveals that chemical reaction does occur, and the nature of the compound formed shows what constituents of coating and core metal take part in the reaction. For another, the identification of the film will enable measurements of resistivity to be made, a physical property which is regarded as playing a considerable part in the behaviour of 'oxide' cathodes. This is to mention but two of the factors which make studies of the interface of these cathodes of interest.

The technique of X-ray analysis has been used by Fineman and Eisenstein to examine the 'oxide' cathode 'interfaces'. This method has also been employed in these Laboratories with successful results. A reference to an identification of the interface for a base metal consisting of nickel alloyed with a small percentage of aluminium was made in a paper to the Royal Society of Arts in 1940[3]. Because of the recent rise of interest in this feature of 'oxide' cathodes, it has been thought worth while to summarize the results so far obtained.

A variety of specimens has been studied, both from experimental diodes and from more formal thermionic devices, and three principal base metals have been included, namely, nickel containing aluminium, silicon and titanium respectively. The 'oxide' coating was invariably formed from a barium–strontium carbonate solid solution of the conventional type, in which barium and strontium carbonates were present in equimolecular proportions. After vacuum processing and activation of the cathodes, the thermionic devices were opened to the atmosphere, and then the coatings scraped away so as to expose the interface at the base metal. No special precautions have been taken to prevent reaction of the interface compound with the atmosphere.

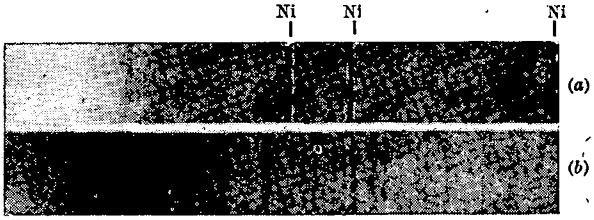
X-ray examination was carried out in most instances by glancing-angle reflexion technique, using copper $K\alpha$ radiation and a circular camera of 19 cm. diameter. In one or two instances the interfacial film was thick enough for filings to be made, but X-ray analyses of such specimens did not yield results differing in any significant respect from that obtained by the surface reflexion technique.

The results are presented in tabulated form below:

Base-metal	X-ray analysis	Standard of comparison made from:
Nickel with 2 per cent aluminium	Barium aluminate, $BaO.Al_2O_3$	Equimolecular proportions of $BaCO_3$ and Al_2O_3 heated to 1,200° C. in air
Nickel with 0·4 per cent silicon	Barium orthosilicate, Ba_2SiO_4*	Mixture of $BaCO_3$ and SiO_2 (finely ground flint) in molecular ratio 2 : 1 heated to 1,300° C. in air
Nickel with 0·23 per cent titanium	Barium orthotitanate, Ba_2TiO_4	Mixture of $BaCO_3$ and TiO_2 in molecular ratio 2 : 1 heated to 1,300° C. in air.

* In Fineman and Eisenstein's paper the interface compound is stated to be "$BaSiO_3$"; but after correspondence, they agree with the results reported here.

The accompanying photograph illustrates the X-ray identification of barium orthotitanate as the interface compound on an 'oxide' cathode in which a nickel–titanium alloy was the base metal.



PARTS OF X-RAY DIFFRACTION PATTERNS (19-CM. CAMERA, COPPER $K\alpha$ RADIATION) OF (a) INTERFACE OF 'OXIDE' CATHODE WITH NICKEL–TITANIUM BASE METAL; (b) PURE BARIUM TITANATE

It is noteworthy that only barium compounds appear to be formed. There is no evidence that any solid solution of an isomorphous strontium compound occurs. This result is also obtained by Fineman and Eisenstein. It is known that isomorphous replacement of barium by strontium can occur with the orthosilicates and orthotitanates prepared for comparison purposes.

Another interesting crystallographic feature is that barium orthotitanate and barium orthosilicate appear to be structurally isomorphous. This is shown by the very close similarity in their Debye–Scherrer powder photographs. Of the two compounds the titanate has the larger lattice parameters. It is not known whether this crystallographic similarity has any significance so far as the thermionic behaviour is concerned.

Crystal Structure of Co[Hg(CNS)₄]

AN X-ray investigation of $Co[Hg(CNS)_4]$ was undertaken in conjunction with work on similar compounds to determine the co-ordination of the complex ion.

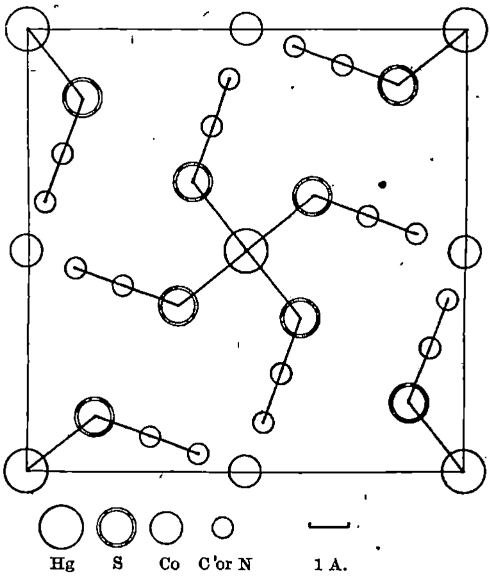
The compound crystallizes in deep purple, tetragonal, prismatic needles of crystal class $\bar{4}(S_4)$ and space group $I\bar{4}(S_4^2)$. $a = 11{\cdot}09$ A.; $c = 4{\cdot}37$ A. There are two molecules per unit cell.

From Patterson and Fourier syntheses of the $hk0$ and $h0l$ zones, the co-ordinates of Hg, Co and S are:

Hg: 0,0,0; Co: $\frac{1}{2},0,\frac{1}{4}$ *or* $\frac{1}{2},0,\frac{3}{4}$; S: 0·15, 0·13, 0·28.

This gives an Hg—S distance of 2·5 A. It appears reasonably certain that the S atom is attached to the Hg in tetrahedral co-ordination, with S—Hg—S angles of 120° and 104°.

The indications of the Fourier syntheses are that S—C≡N is straight, with N co-ordinated about Co (see diagram).



PROJECTION ON THE c-FACE

The investigation is being continued with the object of obtaining accurate co-ordinates for all the atoms.

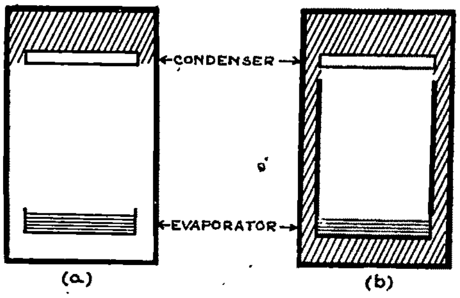
Effect of Shape of Operating Chamber in the Freeze-drying Process

A RECENT communication[1] discusses the freeze-drying process as conducted with the pressure of permanent gas, and the vapour pressure of the ice on the condenser, maintained at very low levels. Research on the application of the process to foodstuffs is being conducted at the Low Temperature Research Station, Cambridge. It seemed likely that the need to operate at extremely low pressures might be undesirable economically in such applications, and accordingly other factors which affect the efficiency of the process have been investigated, including air pressures up to 1 mm. mercury and condenser temperatures of $-20°$ C. and higher. The results show, as will be made clear below, that the design of the space in which freeze-drying is proceeding materially affects efficiency.

Using a frozen mixture of copper filings and boiled, distilled water as the evaporator in order to reduce temperature gradients, it is found that the vapour pressures in the immediate vicinity of the evaporating and condensing surfaces are sensibly equal to the saturation vapour pressures of ice at the temperatures of these surfaces. The air in the system distributes itself in such a way that the total pressure is everywhere the same, provided mechanical obstruction is negligible, so that more air collects near the condenser than near the evaporator. The variation of the partial pressure of air p from the evaporator to the condenser follows the law $p = A \exp. Bx$, where x is the distance from the evaporator, and the mean air pressure in the system can be calculated from the formula $\pi = \dfrac{p_c - p_l}{\log_e (p_c/p_l)}$, where p_c, p_l are the partial pressures of air near the condenser and evaporator respectively. It is presumed that this distribution of partial pressures results from a general movement of the mixture of air and vapour from the evaporator to the condenser, due to a difference in total pressure which is too small to be measured, together with movements of air and vapour by diffusion under their own gradients of partial pressure.

If a certain rate of heating be applied to the evaporator, its temperature takes up a value such that the resulting rate of drying removes an equal amount of latent heat. If the system is 'efficient' this will be achieved at a comparatively low temperature; an inefficient system will result in a high temperature. A convenient index of 'efficiency' in this sense is provided by the difference Δp between the vapour pressures at the evaporator and condenser which is set up when a standard rate of evaporation is maintained. It is found that Δp is directly proportional to the mean air pressure π over the range investigated (0·01–1·0 mm. mercury), so that from this point of view the amount of air in the system should be reduced to a minimum.

It has been mentioned that the partial pressure of air near the condenser is relatively high. Any space in the system which is 'screened' by the condenser also contains air at this pressure; and if this space is large, a substantial proportion of the air in the system will be driven into it when evaporation commences, so that the air pressure in the rest of the system will be considerably reduced. In this way a low value of Δp can be obtained even though the total amount of air in the system may be comparatively high. For example, a simple system such as that shown in (*a*) of the diagram gave $\Delta p = 1{\cdot}7$ mm. at a mean air pressure of 0·9 mm.; the addition of a tube as shown in (*b*) produced a considerable increase in the volume screened by the condenser, and a value of $\Delta p = 1{\cdot}1$ mm. was obtained.



CROSS-SECTIONS OF SIMPLE CYLINDRICAL DESICCATORS. THE AREAS SHADED ARE SCREENED BY THE CONDENSER

The appearance of the condensed ice varies with the air pressure and the temperature of the condenser. At low pressures and temperatures, the formation is similar to that described by Bradish *et al.*[1] with a slightly milky appearance. At temperatures of $-10°$ C. and thereabouts, with low air pressures, a glassy, transparent deposit of maximum density is obtained. At air pressures in the neighbourhood of 0·5 mm. mercury, the deposit is milky with a surface of flat, crystalline facets up to 3 mm. across; and pressures of 1 mm. mercury and above give a completely opaque, 'granular' deposit.

Further work in progress includes an investigation into the drying characteristics of various foodstuffs.

Velocity of Electromagnetic Waves

THE determination of the velocity of light has attracted the attention of many scientific workers and, in spite of the experimental difficulties involved, its value is now known with a probable error of about 5 parts in 10^5. The velocity of electromagnetic waves, represented in Maxwell's theory by the quantity $1/\sqrt{\mu k}$, where μ is the permeability and k the permittivity of the medium, is generally assumed to have the same value as that of light; and although the electrical measurements made so far are less accurate than those of the velocity of light, they have served to establish the equality of the two constants within the limits of experimental error. Other electrical methods have become practicable as a result of the techniques employing centimetric waves developed during the last few years. The one dealt with in this note depends on the electrical resonance of a short length of a wave-guide closed at both ends. The frequency of resonance of a cylindrical guide of diameter D and length L is

$$f_n = v \sqrt{\left(\frac{r}{\pi D}\right)^2 + \left(\frac{n}{2L}\right)^2},$$

in which v represents $1/\sqrt{\mu k}$, r is a constant for a particular mode of resonance and n is the number of half wave-lengths in the guide.

This formula is based on the assumption that the walls of the guide are perfectly conducting. Their finite conductivity can be taken into account by introducing a small correction factor in terms of Q, the quality factor, of the resonator. The value of v then becomes

$$v = f_n \left(1 + \frac{1}{2Q}\right) \Big/ \sqrt{\left(\frac{r}{\pi D}\right)^2 + \left(\frac{n}{2L}\right)^2}.$$

The quantities f_n, D, L and $\left(1 + \dfrac{1}{2Q}\right)$ can all be measured with a precision of a few parts in 10^6, and the accuracy of a single measurement should therefore compare favourably with that of the velocity of light, which is based on a large number of observations.

Measurements of the velocity in a vacuum have been made, using the E_{010} and E_{011} modes in one particular resonator. The values of the velocity term obtained for the two modes differ by 2 parts in 10^5, the average value for the velocity of electric waves in a vacuum being

$$v_0 = 299,793 \text{ km./s.}$$

The maximum error, including residual effects due to the method of coupling the resonator to a source of oscillations, is estimated to be ± 3 parts in 10^5, which is approximately ± 9 km./s.

The value of velocity is 17 km./s. greater than that generally accepted for the velocity of light, although the values are not in disagreement when the combined limits of error are taken into account. In view of the possible discrepancy, however, it is proposed to make measurements of other modes in resonators of different shapes, in order to obtain further experimental evidence of the possible sources of error.

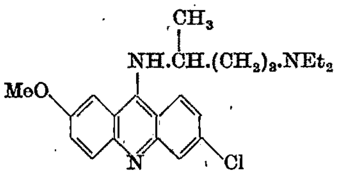
Resolution of Mepacrine

MEPACRINE (2-chloro-5-(δ-diethylamino-α-methylbutyl)amino-7-methoxyacridine) has been resolved by Tschelincev and Osetrova[1], by the use of what they describe as αα′-bromcamphorsulphonic acid.



Mepacrine

We have failed to effect resolution with any of the available bromcamphorsulphonic acids, though Dr. Trenner, of Merck and Co., U.S.A., has succeeded with *d*-α-bromcamphor-π-sulphonic acid[2]. We have, however, carried out a complete resolution by means of *d*-4 : 6 : 4′ : 6′-tetranitrodiphenic acid. Full details will be given in another place; in the meantime, we wish to record our values for the specific rotation of the hydrochlorides of the optical antimers in water. We find:

$[\alpha]_D^{14°} = -379 \pm 6°$ (m.p. 244–5°, decomp.; uncorr.).

$[\alpha]_D^{10°} = +388 \pm 7°$ (m.p. 244–5°, decomp.; uncorr.).

Tschelincev and Osetrova[1] give:

$[\alpha]_D = -357°$ (m.p. 243°, decomp.).

$[\alpha]_D = +358{\cdot}6°$ (m.p. 243°, decomp.).

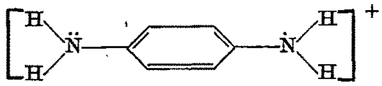
Polymerization of a Semiquinone Ion

THE most recent theory of the structure of Wurster type dyes (oxidation products of *p*-phenylenediamines) is that of Granick and Michaelis[1]. One of their main conclusions was that polymerization of a semiquinone ion of the type depicted below is impossible



when all the amino hydrogens are substituted. In support of this conclusion, they instanced the existence of a crystalline perchlorate of Wurster's Blue (the oxidation product or δ-salt of tetramethyl paraphenylenediamine)[2] the paramagnetism of which indicates the presence in the molecule of one unpaired electron.

By oxidizing tetramethylbenzidine with aqueous bromine in the presence of sodium perchlorate, we have prepared a deep-green crystalline perchlorate which catalytic micro-reduction shows to be on the oxidation level of a semiquinone. The striking thing about this green salt is that it is diamagnetic ($\psi_M = -166 \times 10^{-6}$ c.g.s. units). Thus polymerization of this semiquinone ion occurs in spite of the fact that all the amino hydrogens are substituted. It is clear that some modification of the existing theory of polymerization of semiquinone ions of the above type is required. Details of proposed modifications and work on related compounds will be published shortly.

Size Versus Colour in Air-Sea Rescue

I AM indebted to the Air Ministry and especially to the civilian staff of the Air-Sea Warfare Development Unit for a copy of the valuable report on "The Optimum Dinghy Colour for Air-Sea Rescue". Colours were tried from a yellow close to the Schott glass O.G.1, through orange and fire orange, near Schott O.G.2, onwards to traffic red and post-office red, like Schott R.G.1. The overall average visual range of the five coloured *M*-type dinghies for all-round weather conditions around the British Isles was approximately 1·7 nautical miles (3·15 km.). The waters were mostly greenish, but this is not always so on our coasts.

For the blue Mediterranean the visual ranges were, yellow dinghy 4 naut. miles (7·41 km.); orange and fire orange, 3 naut. miles (5·56 km.); reds, 2·5 naut. miles (4·63 km.). These are significantly different. But there was no such difference between the maximum visibility distance as a definitely coloured object on any sea colour. On green and blue seas, the observers favoured dinghies which appeared orange. This agrees with my own observations using the Schott glasses at sea, for the clearest view is obtainable with O.G.2.

After preliminary tests, the observations were made at 240 m. The diameter of the dinghy being 2·5 m. the angular size at the limiting ranges was, as the report points out, of the order of 0·05°. Actually the size is about one minute of arc for the greatest range (7·4 km.), nearly two minutes for the red range (4·6 km.) and nearly seven minutes for the British waters range (3·15 km.). Now Helmholtz has shown that the minimum perceptible brightness difference increases from about 2 per cent for an angular size 3° ; from his curve one finds (by extrapolation) that the minimum perceptible brightness difference has increased to about 40 per cent for the 7-km. range, about 35 per cent for the 5·5-km. range, and for the 3-km. range to about 27 per cent. As the effect of the atmosphere is to introduce a greyness into the colours, it is clear that the high values of the minimum perceptible brightness differences are the real limits to vision. Put simply, the objects become too small to see, quite irrespective of their colour.

It should be possible to increase the 'size' of the object by liberating oil. In the past, use has been made of fluorescein powder, which should the "multitudinous seas incarnadine", and this has been given off by airmen's suits (namely, packet on life-jacket). But the colour is obviously soon diluted, and in any event a volume effect is produced as against a surface effect for oil. The action of the latter is, according to N. K. Adam, "to damp out the small ripples which are constantly being formed by the action of wind". The water surface at a distance makes, therefore, a smaller average angle with the eye, and so its reflexion is greater. This reflexion amounts to 40 per cent for 5°, and is increasing rapidly as the angle between sea and line of sight diminishes. There is, in addition, the difference due to the refractive indices of oil and water; but a trial on calm water showed this to be negligible. I am indebted to Prof. Adam for the guess that a fuel oil will spread to a thickness of at most one micron on a clean sea ; at this one should have the higher orders of interference colours, which are surely observed. One kilogram of oil would, therefore, cover at least 1,000 sq. metres, giving a patch 30–40 m. in diameter. At the farthest range observed, namely, 7·4 km., such a patch would subtend an angle of about 15′, corresponding to a minimum perceptible brightness difference of about 17 per cent, as against 40 per cent for the dinghy; for British waters, 3·15 km., the angle would be 35′, corresponding to a 7 per cent minimum brightness discrimination. Thus increase in size should considerably extend the visual range, for dinghies plus oil, as against dinghies alone.

An obvious method of increasing the angular dimensions of an object is, of course, to use field-glasses; but it appears that the limitation of the field of view renders them valueless in ocean search —at least, no mention was made of them in the report.

The rate of spreading of oil on water may be about 12 m. a minute[1], so were a dinghy to liberate oil on sighting an aeroplane, a good-sized patch should rapidly be produced. So many factors are concerned in trials of this sort that direct observation seems the only way to reach a conclusion.

Chemical Effects of Moonlight

The article by Dr. C. F. C. Beeson in *Nature* of October 26, p. 572, is a welcome attempt to sort out the many conflicting references to a subject of much importance and of wide interest. Numerous factors go to the growth of a plant, and I felt many years ago that it was necessary first to find out the chemical and physical effects of moonlight under simple controlled conditions. The research was carried out chiefly under the bright moonlight of South Africa. Moonlight is partially polarized, the maximum effect being with the oblique reflexion of half-moon, or somewhat later for the waxing and earlier for the waning moon.

The experiments were as follows :

(*a*) Exposure of seeds to the night sky at periods of half-moon and of no moon. There was marked increase of germination in those seeds in which the testa was thin and transparent. These experiments were simply exploratory but led to the inquiry as to the effect of moonlight on reserve food material.

(*b*) Exposure of starch grains, washed and mounted on a microscope slide, *without* a cover glass. No diastase was added, but the water contained 0·05 per cent sodium chloride as co-enzyme. After about three hours the slide was covered and left to dry. Crystals were seen forming within the grains and exuding from them, also in the surrounding film of liquid.

(*c*) Exposure of a film of *boiled* starch. On drying, crystals were seen forming stars and rosettes, and on treating with Fehling solution the change to a sugar was indicated by countless specks of cuprous oxide.

(*d*) In the living plant (chiefly in South Africa). Young leaves of *Tropæolum* and of spinach were partially covered by tinfoil, leaving a small portion exposed to the moonlight. In the exposed region the starch disappeared, while the covered portion still gave the blue colour with iodine. This effect was also shown in a shaded vine-leaf[1]. A similar effect can be produced on films of boiled starch on filter paper. A penny placed on top of a sheet of *thin* glass, with a film of starch on the under side, after exposure to moonlight, gave a distinct image of the shadow on staining the film with iodine.

(*e*) At the request of a consulting timber engineer, determinations of the sap content at different phases of the moon were commenced. Equal weights of vine stems were boiled and the solutions were tested for sugar after (i) a period of half-moon, (ii) after an equal period of minimum light. The result showed nearly twice as much reduction in the first case as in the second: (i) required 16·5 c.c., (ii) required 29·9 c.c. of the solution to reduce equal quantities of Benedict solution.

From these experiments, the results of which are similar to those obtained with artificially polarized light[2], it appears that moonlight, being polarized, has a hydrolysing effect on reserve food, that is, it acts as a digestive tonic. Now to live on digestive tonics, especially without extra food, may be disastrous—hence the conflicting results which have been recorded.

Most of the experiments referred to above are quite simple, and can easily be reproduced. They should help to dispel the idea of 'superstition' and 'old wives' fables'.

Elizabeth Sidney Semmens

RESEARCH IN BRITISH COLONIAL TERRITORIES

UNDER the title "Colonial Research, 1945–46" there have been issued (Colonial No. 208. H.M.S.O., London, 1947. 1*s*. net) the third annual reports of the Colonial Research Committee and the Colonial Products Research Council, the second annual report of the Colonial Social Science Research Council and the first annual reports of the Colonial Medical Research Committee and the Committee for Colonial, Agricultural, Animal Health and Forestry Research.

The year 1945–46 marked the completion of the main organisation and framework in London for the continuous survey of the needs of Colonial research, and the report of the Colonial Research Committee, after summarizing the arrangements made, appropriately takes stock of the results of some six years experience of the provision for research under the Colonial Development and Welfare Act, with which the Committee has been concerned since its creation in 1942. The cumulative total of research allocations under the Act now exceeds £1,000,000, and of 105 schemes made during the period since the Act came into force, 54 were made during the year 1945–46, when actual expenditure was £93,306 as against £58,345 in the previous year; the total expenditure to date is £202,565.

A main function of the Committee is to achieve the maximum degree of co-ordination of effort as between the various branches of science represented not merely by the bodies reporting in the present publication but also by the Economic Research Sub-Committee of the Colonial Economic Advisory Committee, the Colonial Fisheries Advisory Committee, the Tsetse Fly and Trypanosomiasis Committee, the Colonial Survey and Geophysical Committee and other specialist committees which are directly advisory to the Secretary of State for the Colonies. This task is being eased as there become available the long-term development plans of the various Colonies and regions with reference to the best use of the development funds available under the Colonial Development and Welfare Act. These plans indicate where the major efforts will be made and where in consequence a parallel research effort will be of the greatest value. Moreover, the Committee considers that studies of the bases of plans already formulated or being formulated are among the most fruitful objects to which a part of the research effort may be directed, and may constitute the essential foundation for fruitful research in many fields and for wise and efficient development planning.

While this report lists in an appendix the schemes recommended and finally approved during the period April 1, 1945–March 31, 1946, the Committee records progress only in those fields not covered by one or other of the specialist bodies. The report notes that it has now been decided to proceed with the scheme for establishing a central organisation for geodetic and topographical surveys, and Brigadier M. Hotine has been appointed director of Colonial (geodetic and topographical) surveys. The scheme, in which the Royal Air Force and the United States Army Air Force are participating, will allow the topographical mapping of large areas of the Colonies at a speed far in excess of anything achieved by ground methods before the War. It will also make available air photographs which can be of considerable value to forestry, agricultural and other officers in the Colonies in their ordinary work. Steps are also being taken to establish a Colonial geological survey on broadly similar lines, and work is expected to commence shortly on the preparation of plans for a freshwater fisheries research station on the shores of Lake Victoria at Jinja, Uganda, under a scheme to provide capital cost and running expenses for five years. Surveys of the Colonial fisheries in the Caribbean area have been completed, and plans are being drawn up for a fisheries research station for this area, which will probably be located in Trinidad. A further scheme provides a sum of £30,000 for the purchase and running costs for two years of a research vessel to investigate the fisheries of the Mauritius–Seychelles banks, which, it is hoped, will be in charge of Dr. J. E. Wheeler. Mr. J. S. Colman, lecturer in biology, University of Sheffield, completed a survey of the fisheries of St. Helena which suggested that policy should be directed towards improving the local supply of fish by means of better fishing methods and the improvement of distribution.

The Committee endorsed the recommendations of the report of the Colonial Housing Research Group for the establishment in Great Britain of a Colonial housing bureau for the collection and dissemination of information, to work in close association with the Building Research Station, and the establishment of housing research stations in the Colonies on a regional basis. It has also recommended the appointment in the Colonies of housing committees, representative of all the specialist interests concerned, and the appointment of an advisory committee in London; these proposals have been commended to Colonial Governments by the Secretary of State. As regards tsetse fly and trypanosomiasis, the main developments during the year were visits by Prof. P. A. Buxton, of the London School of Hygiene and Tropical Medicine, to East Africa, and by Prof. T. H. Davey, of the Liverpool School of Tropical Medicine, to West Africa, while the urgency of promoting experiments and research in the use of D.D.T. and other insecticides and repellents against tsetse led to a scheme for employing a Colonial Insecticide Research Unit in East Africa, for which a research grant of £41,500 over two years was made under the Colonial Development and Welfare Act. Arrangements were initiated for therapeutical field trials of phenanthridinium compounds. The Anti-Locust Research Centre has conducted extensive anti-locust campaigns with the usual methods of ground attack, but an Anti-Locust Flight of the R.A.F. has also been established with the object of exploring the possible use of aircraft; experimental operations in Saudi Arabia and in Kenya have justified further work.

In July 1945 a Land Tenure Advisory Panel was set up to advise on the general lines of research into native land questions and related matters; to review and co-ordinate the results of local investigations to provide information for the Colonial Governments on systems of land tenure; and to advise on research aspects of general questions of land policy.

The third annual report of the Colonial Products Research Council also reviews general progress Apart from research directly sponsored by the Council, notable progress has been made in encouraging and assisting workers already in the field, in effecting contacts and bringing new processes and discoveries to the notice of those who might be in a position to carry them further. A list of eight paten applications appended to the report illustrates th extent to which work has already reached a stage ripe for industrial exploitation. Importance continues to be attached to the personal contacts between workers in Great Britain and in the Colonies. Dr. H. H. Storey, director of the East African Industrial Research Board, visited Britain and discussed proposals with the Council for setting that organisation on a permanent footing.

Work under Prof. T. P. Hilditch has greatly improved and simplified methods for analysing vegetable oils and fats, and a number of oil-seeds are at present under investigation, including Ceylon and Nigerian rubber seed oils and citrus oil seeds. The investigation under Prof. A. R. Todd into the nature of the active principle in the flowers of *Hagenia abyssinica* (*Brayera anthelmintica*) has been actively pursued, and a list of indigenous plants of the Colonial Empire of possible medicinal or insecticidal value has now been completed and circulated. Work has also been carried out on the exact determination of the pain-deadening power of drugs; a method evolved which will detect the action of as little as 5 mgm./kgm. of pethidine hydrochloride is being used in the examination of the analgesic action of sugar derivatives prepared in Sir Norman Haworth's laboratory. The Council is also planning an investigation of really adequate means of studying the action of drugs on intestinal parasites of man and beast.

Substantial progress has been made with the work on sisal carried out for the East African sisal industry under Prof. J. B. Speakman, and has thrown much light on the fundamental nature and properties of sisal. Pyrethrum research at the Imperial College of Science and Technology under Prof. J. W. Munro has been hampered by inadequate facilities. The Council has also considered the technical equipment of the St. Vincent arrowroot industry, and it is hoped to devise in Great Britain much more efficient extraction methods. A wide programme of researches on starch at the University of Birmingham includes further fundamental studies on arrowroot as well as on potato starch and those from cassava, pea and rice. A detailed study is being made of the enzymes present in potato starch, and work on the utilization of sucrose has been concerned mainly with the dianhydrides of mannitol and sorbitol, lævulinic acid and methylolfurfuraldehyde. The examination of the ester fractions of naphthenic acids from Trinidad has commenced under Sir Robert Robinson, and plans for the design of a Colonial microbiological research institute in Trinidad have been approved. Pending the completion of the new laboratory, Messrs. Glaxo Laboratories, Ltd., have offered Dr. A. C. Thaysen accommodation at Greenford, Middlesex, where work on micromanipulation, the growth curve of *Torulopsis utilis*, the organism used in food yeast production, and on the antibiotic action of an actinomycete which yields a substance capable of inhibiting the growth of *Fusarium oxysporum cubense*, a fungus responsible for Panama disease of bananas, is being carried out. Contact has been maintained with the Tin Research Institute.

The second annual report of the Colonial Social Science Council again refers to the need for sound demographic data, and to the necessity of establishing local and regional social research institutes, which can survey the needs of the regions in which they are located and assume responsibility for the supervision and organisation of individual research projects. The Council has accordingly approved a grant to enable the Rhodes–Livingstone Institute to extend its programme of work in Central Africa, and is co-operating in the appointment of a director and staff for the Institute of Social Research attached to Makerere College in East Africa. The end of the War brought a slight mitigation in the shortage of personnel trained for social investigation, and in the meantime the Council has continued to favour team-research involving collaboration between workers in different disciplines, partly because of the direct advantages of such co-operation, and partly because not all the members of the team need have had previous field experience. Specific projects approved during the period include studies of the legal aspects of land tenure in the Gold Coast, the political organisation of typical communities in the Gambia, mental illness and juvenile delinquency in West Africa, grammatical structure of Kikuyu, social and economic conditions in the Aden Protectorate, and the occupational structure of representative communities in the Gold Coast as influenced by war-time Government expenditure. The latter survey and a computation of national income, production and expenditure in Northern Rhodesia and Nyasaland are under the supervision of the Economic Research Sub-Committee.

The first annual report of the Colonial Medical Research Committee refers to the appointment of Dr. A. F. Mahaffy as director of the new Colonial Medical Research Service, and joint secretary, with Dr. F. Hawking, of the Committee. The Committee has recommended that the Service should be staffed with men recruited for whole-time medical research and organised and controlled from Great Britain; although men might be seconded from it for research in the Colonial laboratories staffed by the local governments. It is planned to make the terms of service at least as attractive as those of the Colonial Medical Service, with liberal allowance for leave to continue or develop medical researches in Britain, and arrangements for pension or superannuation facilitating interchange of personnel between the Service and academic appointments in Great Britain. The Committee has agreed that special attention should be paid, as soon as possible, to problems of nutrition; the control of malaria and mosquitoes by new anti-malarial drugs and by the new insecticides; and to filariasis, schistosomiasis, and the physiology of hot climates; but the general policy has been to try to obtain men of initiative and originality and to encourage them to choose their own problems and methods of approach. To encourage training of young men for such research and specialist appointments, the grant of up to ten Colonial medical research studentships to graduates of British universities has been recommended. A Malaria Sub-Committee has been set up and has given its first attention to field trials and similar investigations on the new antimalarial, paludrine. The organisation of therapeutic trials in the Colonies of new remedies has been discussed generally, and it has been arranged that such requests should be made first to the Committee; and, where approved, the trials organised in accordance with the general policy of the Medical Research Council. The Committee has recommended to the Indian Medical Liaison Committee for sympathetic consideration a proposal to establish a small testing station in the tropics for examining chemotherapeutic substances acting on microfilariæ *in vitro*. Proposals for research on the physiology of hot climates have been discussed with Dr. S. S. Ladell; investigation of the epidemiology of an outbreak of poliomyelitis in

Mauritius in 1945 indicated that the disease was endemic, there being malnutrition, overcrowding and increased prevalence of intestinal disease throughout the island at the time. The Committee has also recommended that it should accept the responsibility for taking over and staffing in two years time the research laboratories which the Rockefeller Foundation has established at Entebbe, Uganda, and Lagos, Nigeria.

The first annual report of the Committee for Colonial Agricultural, Animal Health and Forestry Research, established in June 1945, gives the detailed terms of reference of the Committee, which are determined so as to delineate clearly the functions as between the Committee and the Colonial Advisory Council for Agriculture, Animal Health and Forestry. Full co-operation is secured by overlapping membership and close contact between the secretariats of the two bodies. The Committee met seven times during the period and has set up a sub-committee on policy to facilitate consideration of basic policy. The most important matters before the Committee were the re-organisation and expansion of regional agricultural research in East Africa, and the organisation of oil palm research in West Africa; both raised the question of the distribution of research effort between basic and general problems of given regions and problems of particular crops of actual or potential economic importance. Generally, the Committee inclines to the view that the basic and general approach is the one which will be most fruitful in the long run, and it has also reached the provisional conclusion that institutions are required which can devote themselves without interruption to the study of long-term problems. Questions of personnel and terms of service as well as of the control of scientific work have also engaged the attention of the Committee, which hopes to present in its next annual report a clear statement of the general lines of policy which it is intended to follow.

REPORTS OF THE ATOMIC ENERGY COMMISSION

THE first report of the Atomic Energy Commission to the Security Council of the United Nations, dated December 31, 1946, includes first reports also on scientific and technical aspects of the problem of control and on the safeguards required to ensure the use of atomic energy only for peaceful purposes*. The Commission records its approval of the former report from the Scientific and Technical Committee and incorporates in its findings the conclusions of that Committee. A summary is given of the second report, also approved by the Commission, which has reached the further general finding that scientifically, technologically and practically, it is feasible to extend among all nations the exchange of basic scientific information on atomic energy for peaceful ends, to control atomic energy to the extent necessary to ensure its use only for peaceful purposes, to eliminate atomic weapons from national armaments and to provide effective safeguards by way of inspection and other means to protect complying States against the hazards of violations and evasions. Effective control of atomic energy depends at present upon effective control of the production and use of uranium, thorium and their fissionable derivatives. The development and use of atomic energy are not regarded as essentially matters of domestic concern of the individual nations, but rather have predominantly international implications and repercussions. An effective system of control must be international and established by an enforceable multilateral treaty or convention administered and operated by an international organ or operation within the United Nations, possessing adequate powers, and properly organised, staffed and equipped for the purpose. International agreement to outlaw the national production, possession, and use of atomic energy is an essential part of any such international system of control and inspection, although standing alone such agreement would be ineffective.

In accordance with these findings, the Commission recommends the establishment of a strong and comprehensive international system of control and inspection, the scope and functions of which should be defined by a treaty or convention, and which should become operative only when those members of the United Nations necessary to assure its success have bound themselves to accept and support it by signing and ratifying the treaty or convention. It is recommended also that the treaty shall include a clause to the effect that the rule of unanimity of the permanent members of the Security Council shall not relate to the work of the control agency, and that no Government shall possess any right of veto over the fulfilment by the agency of any of its obligations under the treaty. In addition to promoting the exchange of basic scientific information on atomic energy for peaceful ends and its responsibility for preventing the use of atomic energy for destructive purposes, the agency should have responsibilities for research and development in order to remain in the forefront of atomic knowledge. The exclusive right to carry on atomic research for destructive purposes should be vested in the agency, which should also establish appropriate safeguards for research in nuclear physics having a direct bearing on the use of atomic energy. Such safeguards should not interfere with the prosecution of scientific research, or the publication of its results, provided no dangerous use or purpose is involved. The treaty or convention should embrace the entire programme for putting the international system of control and inspection into effect and should provide a schedule for the completion of the transitional process over a period of time, step by step, in an orderly and agreed sequence leading to the full and effective establishment of international control.

At its meeting on March 10, the Security Counci referred back to the Commission this first report with a request to prepare a draft treaty or convention incorporating its ultimate proposals, and to submit a second report before the next session of the Genera Assembly. Mr. A. A. Gromyko's statement of the U.S.S.R.'s position, on March 5, ignored the Commission's finding that prohibition of atomic weapons would be ineffective except as part of a system o international inspection. He rejected the whole idea of inspection and of infringements of nationa sovereignty, and distorted the conception of the international control agency developed in the report as well as the comments of the Council of the Atomic Scientists' Association on the American and Russia proposals before the Commission (see *Nature*, 159, 47; 1947) without advancing any constructive proposals to meet the difficulties he stressed. At the Security Council's meeting on March 10, Mr. W. R

Austin vigorously refuted the allegation that the United States sought either a monopoly or to impose its will on other countries in questions of atomic energy. Referring to the Declaration of November 15, 1945, by the President of the United States and the Prime Ministers of the United Kingdom and of Canada, Mr. Austin said that the United States Government had made it clear that it welcomed all constructive suggestions which might advance the solution of the common problem and fulfil the mandate of the General Assembly resolution. Strong support for the United States position was forthcoming from the French delegation, and those of China and Australia.

HORMONES AND FRUIT-FALL

THE year 1939 marked the publication by F. E. Gardner, P. C. Marth and L. P. Batjer of their important discovery that the spraying of synthetic growth-substances on young apples prevented the natural shedding of fruit, which often reduced the crop quite substantially. These findings have been confirmed and expanded by many workers, and Dr. M. C. Vyvyan, of East Malling, has summarized the large amount of research which has been done on the subject*.

Fruit-drop has several causes. It may arise from structural defects, from non-pollination, from various ypes of non-fertilization, and from the abortion of embryos; nutritional conditions also seem important. One section of the bulletin considers the proportion of blossom which will become mature fruit, and another part records some of the variations in fruit-fall according to variety. The mechanism of abscission may, or may not, involve cell division, and these differing types of fruit-fall may be related to variations in response to growth substances. Certain naphthalene derivatives, for example, exert a marked effect on pre-harvest drop of many apple varieties, but have little or no effect in preventing 'June drop'.

A careful and detailed tabulation of extensive results allows certain generalizations. For the control of fruit-drop with most varieties, "nothing better han naphthaleneacetic acid or the acetamide seems o be required". Evidence on the optimum concentration is rather conflicting, but in most cases it is probably best to use the 'standard' concentration of 10 p.p.m. Temperatures between spraying and picking seem to influence the duration rather than he intensity of spray effect. Rain may be harmful if it falls before the spray has had time to dry. Sprays vary in their duration of effect; they are not, however, in general, effective until five or six days after application, and remain active for two or three weeks. The timing of treatment is therefore most important. Pure naphthaleneacetic acid and acetamide are sparingly soluble in water; they are accordingly dissolved in a little alcohol before dilution. The synthetic growth-substances may also be applied as dusts, though further work is necessary before such convenient applications can be recommended for general commercial use. Results reviewed by Dr. Vyvyan do not suggest that fruit retained on the ree by hormone sprays has markedly different storage haracters from fruit ripened normally. Small variaions do, however, occur, and further work is desirable.

This bulletin is an admirable summary of work on the control of fruit-fall. It provides new horticultural equipment for the fruit grower and should give direction and stimulation to further research on the subject. Fruit-fall is not, however, always an unmitigated evil, and while pre-harvest drop provides the clearest need for control by hormone sprays, the ultimate practical control of previous 'drops' may lie in an adjustment, earlier in the season, of the amount of blossom to nutritional potentialities of particular trees. This gentle warning provides no disparagement of the volume under review, for Dr. Vyvyan's text does not introduce synthetic growth-substances as a panacea for all troubles. They rather provide a welcome remedy for a specific difficulty.

JOHN GRAINGER

BIOCHEMISTRY IN BELGIUM

THE relative scientific isolation of the enemy-occupied countries during the War has engendered a determined post-war effort on the part of research workers of such countries to use with the maximum efficiency opportunities to contact workers in other countries. The appearance of publications reviewing the work of the past seven years in as wide a manner as possible is one outcome of this determination.

A series of short monographs is now appearing under the general title "Actualités Biochimiques", published (Liège: Éditions Desoer; Paris: Masson et Cie.) under the editorship of Prof. Marcel Florkin, of the University of Liège. The first of these, written by Prof. Florkin himself in 1945, is entitled "Aperçus sur les Progrès de la Biochimie, dans les Pays Anglo-Saxons, Depuis 1940", and represents a bird's-eye view obtained from visits in June 1945, made possible by Le Fonds National de la Recherche Scientifique de Belgique. This volume surveys work carried out in the United States of America as well as that in Great Britain, and covers an extremely wide field effectively, but in a manner which is necessarily somewhat superficial. The subject of British anti-lewisite (*B.A.L.*) is treated in a later volume (No. 8, published in 1947, entitled "Travaux Récents sur les Toxiques de Guerre"), by Prof. Z. M. Bacq, in which the well-known fascinating story is told with all due credit to the genius of R. A. Peters.

It is unavoidable that the standard of the volumes of this series should vary, since the outlook of the authors is widely different. The second of the series, entitled "Données Récentes sur la Nature et le Métabolisme de L'Os", by Prof. Marcel J. Dallemagne (University of Liège), is an interesting exposition on bone metabolism in which the physical properties are discussed in relation to functional biochemical aspects, and which includes a useful section on hormones. No. 3, on "L'Évolution du Métabolisme des Substances Azotées chez les Animaux", by Prof. Florkin, is a very useful summary of work which is widely scattered and difficult to come by within the covers of one volume, and it is a tribute to biochemists in Belgium that such an insistent interest is shown in comparative aspects of the subject. No. 4 is the first of more than one volume dealing with new methods of clinical analyses, entitled "Méthodes Nouvelles D'Analyse Biochimique et Clinique", by Ghislaine Duchatéau (University of Liège), a subject on which it appears that more information will be given later. No. 5 (Pierre Fredericq) discusses "Données Récentes sur la Coagulation du Sang", while No. 6 deals with

"Acquisitions Récentes dans le Domaine de L'Enzymologie" (Prof. L. Massart). No. 7, by Claude Liébecq (University of Liège), is a useful discussion under the heading "Conception actuelle du Catabolisme de L'Hémoglobine".

The volumes announced for future publication include: "Données Récentes sur les Phosphatases", by Jean Roche and Nguyen-Van Thoai; "L'Acide Ribonucléique", by Jean Brachet; and "Données Récentes sur les Antigènes Bactériens. Constitution chimique et Propriétés Biologiques", by A. Boivin.

This series will be of interest not only to Belgian biochemists but also to all who wish to see a review of recent work provided in a concise form, which although it is by no means exhaustive, provides a key to the most important literature of the last seven years.

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Monday, May 5

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London W.C.2), at 5 p.m.—Dr. D. A. Spencer: "Recent Developments in the Application of Photography" (Cantor Lectures) (further lectures on May 12 and May 19).

SOCIETY OF CHEMICAL INDUSTRY (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Annual General Meeting; Mr. E. Holmes: "Plant Hormones with special reference to Selective Weed Killers".

INSTITUTION OF ELECTRICAL ENGINEERS, LONDON STUDENTS' SECTION (at Savoy Place, Victoria Embankment, London, W.C.2), at 7 p.m.—Mr. Arthur Duxbury: "The Presentation of Technical Information".

CHEMICAL SOCIETY, BIRMINGHAM BRANCH (in the Chemical Lecture Theatre, The University, Birmingham).—Mr. M. C. Paine: "Careers in Chemistry".

Tuesday, May 6

INSTITUTION OF CHEMICAL ENGINEERS (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 2.15 p.m.—Dr. B. A. Southgate: "The Re-Use of Waste Waters from Industrial Processes".

SHEFFIELD METALLURGICAL ASSOCIATION (at 198 West Street, Sheffield), at 7 p.m.—Mr. D. A. Oliver: "Heat-Resisting Steels".

Wednesday, May 7

ROYAL AERONAUTICAL SOCIETY (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 11 a.m.—Discussion on "Naval Aircraft".

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London W.C.2), at 5 p.m.—Mrs. G. E. Abbott: "Gas in the Home".

INSTITUTE OF PETROLEUM (at Manson House, 26 Portland Place, London, W.1), at 5.30 p.m.—Major Kenneth Gordon: "The Development of Hydrogenation and Fischer-Tropsch Processes in Germany".

INSTITUTION OF ELECTRICAL ENGINEERS, RADIO SECTION (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Dr. R. A. Smith, Dr. E. Franklin and Mr. F. B. Whiting: "Accurate Measurement of the Group Velocity of Radio Waves in the Atmosphere, using Radar Technique".

SOCIETY OF PUBLIC ANALYSTS AND OTHER ANALYTICAL CHEMISTS (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6 p.m.—Dr. R. R. Goodall and Dr. A. A. Levi: "A Microchromatographic Method for the Detection and Approximate Determination of the Different Penicillins in a Mixture".

INSTITUTION OF CIVIL ENGINEERS, NORTH-WESTERN ASSOCIATION (at the Engineers' Club, Albert Square, Manchester), at 6.30 p.m.—Annual General Meeting, followed by a Discussion on "The Contract System in Civil Engineering".

BRITISH INSTITUTION OF RADIO ENGINEERS, NORTH-WESTERN SECTION (in the Reynolds Hall, College of Technology, Manchester), at 6.45 p.m.—Mr. E. C. Cherry: "Single Side-Band Communication Channels".

Thursday, May 8

PHYSICAL SOCIETY (in the Physics Department, Imperial College of Science and Technology, Imperial Institute Road, London, S.W.7), at 4.30 p.m.—Annual General Meeting; at 5 p.m.—Prof. D. Brunt, F.R.S.: "Some Aspects of the Heat Balance of the Human Body" (Presidential Address).

ROYAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Mr. R. G. Vines and Mr. M. F. R. Mulcahy: "The Initial Stages of Explosion in Nitroglycerine"; Mr. R. G. Vines and Mr. M. F. R. Mulcahy: "The Propagation of Detonation in Thin Layers of Nitroglycerine".

LINNEAN SOCIETY OF LONDON (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Scientific Papers.

LONDON SCHOOL OF ECONOMICS AND POLITICAL SCIENCE (at Houghton Street, Aldwych, London, W.C.2), at 5 p.m.—Prof. Chi-Yuen Wu: "The General Economic Conditions and Future Development of China" (further lecture to be given on May 22).*

INSTITUTION OF ELECTRICAL ENGINEERS, INSTALLATIONS SECTION (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Mr. C. F. Freeman and Mr. H. V. Mather: "Special Electrical Requirements of a Viscose Rayon Factory".

ROYAL AERONAUTICAL SOCIETY (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 6 p.m.—Mr. E. S. Moult: "The Development of the Goblin Engine".

WOMEN'S ENGINEERING SOCIETY, MANCHESTER BRANCH (at the Engineers' Club, Albert Square, Manchester), at 6.30 p.m.—Miss W. Hackett: "Capacitors—their Manufacture and Testing".

Friday, May 9

PHYSICAL SOCIETY, OPTICAL GROUP (in the Physics Department, Imperial College of Science and Technology, Imperial Institute Road, London, S.W.7), at 3 p.m.—Sixth Annual General Meeting; at 3.15 p.m.—Mr. E. W. H. Selwyn: "Photographic Resolving Power of Lenses".

ROYAL ASTRONOMICAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Prof. M. G. J. Minnaert: "The Fraunhofer Lines of the Sun" (George Darwin Lecture).

CHEMICAL SOCIETY, NEWCASTLE AND DURHAM SECTION (at King's College, Newcastle-upon-Tyne), at 5 p.m.—Prof. E. L. Hirst, F.R.S.: Bedson Club Lecture.

TELEVISION SOCIETY (at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W.C.2), at 6 p.m.—Mr. C. L. Hirshman: "Television Picture Quality".

UNIVERSITY OF GLASGOW (in the Chemistry Lecture Theatre), at 7.30 p.m.—Dr. Douglas Guthrie: "William Cullen and his Times" (other lectures in celebration of the Bicentenary of the Lectureship in Chemistry will be given on May 16, 23 and 30).*

Saturday, May 10

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE, DIVISION FOR SOCIAL AND INTERNATIONAL RELATIONS OF SCIENCE (at the University, Manchester).—Conference on "The Place of Universities in the Community".*

Tuesday, May 6—Saturday, May 24

TOWN AND COUNTRY PLANNING ASSOCIATION (at the Institution of Civil Engineers, Great George Street, London, S.W.1).—Exhibition: "Thirteen Nations Plan for Better Living" (to be opened at 3 p.m. by Mr. Lewis Silkin).

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on o before the dates mentioned:

SENIOR ASSISTANT FOR ELECTRICAL ENGINEERING—The Principa Municipal Technical College, Hopwood Lane, Halifax (May 10).

SENIOR POST IN THE ACOUSTICS SECTION of Research Departmen based in London—The Engineering Establishment Officer, Britis Broadcasting Corporation, Broadcasting House, London, W.1 (May 10)

EDITORIAL OFFICER—The Honorary Secretary, Society of Dyer and Colourists, 32–34 Piccadilly, Bradford, endorsed 'Editorial Officer (May 10).

LECTURER IN SURVEYING in the Mining Department—The Registra The University, Leeds 2 (May 15).

CHAIR OF BOTANY in the University of Tasmania—The Agent General for Tasmania, Golden Cross House, Charing Cross, Londo W.C.2 (May 15).

HEAD OF THE SCIENCE AND TECHNICAL DEPARTMENT of the Norwoo Technical Institute, Knights Hill, West Norwood, London, S.E.27—The Education Officer (T.1), County Hall, London, S.E.1 (May 17).

LECTURER (Grade II), an ASSISTANT LECTURER (Grade III), and a ASSISTANT LECTURER (temporary), in the DEPARTMENT OF PUR MATHEMATICS—The Registrar, The University, Liverpool (May 22

LECTURER and an ASSISTANT LECTURER IN PHYSICS, a LECTURE and an ASSISTANT LECTURER IN CHEMISTRY, an ASSISTANT LECTURE IN ZOOLOGY, and an ASSISTANT LECTURER IN BOTANY AND ZOOLOG (with special reference to Cytogenetics)—The Registrar, The University, Sheffield (May 24).

LECTURER IN BACTERIOLOGY, a SENIOR LECTURER IN PHYSICA CHEMISTRY, and a LECTURER IN FUEL TECHNOLOGY—The Registra The University, Sheffield (May 24).

ASSISTANT LECTURER (Grade III) IN THE DEPARTMENT OF GEOLOG —The Registrar, The University, Liverpool (May 27).

PROFESSOR OF GEOLOGY—The Registrar, University College Wales, Aberystwyth (May 30).

PAINT ADVISER by the Government of Nigeria—The Director Recruitment, Colonial Service, 15 Victoria Street, London, S.W.1.

LABORATORY ASSISTANT IN THE DEPARTMENT OF PHYSICS, and LABORATORY ASSISTANT IN THE DEPARTMENT OF CHEMISTRY—Th Registrar, University College, Singleton Park, Swansea.

ENGINEER with practical knowledge of drawing, design and develo ment, a CHEMIST for physico-chemical research, and DEVELOPMEN OFFICERS (chemists or chemical engineers, preferably with some work experience)—The Director, British Launderers' Research Associatio Laboratories, Hill View Gardens, Hendon, London, N.W.4.

SENIOR LECTURER IN PHYSICAL CHEMISTRY—The Clerk to th Governors, Northern Polytechnic, Holloway, London, N.7.

PHYSICIST for research work in high-vacuum technique—Th Director and Secretary, British Scientific Instrument Researc Association, 26 Russell Square, London, W.C.1.

TEMPORARY POST in London with the Directorate of Ordnan Factories, Ministry of Supply—The Ministry of Labour and Nation Service, Technical and Scientific Register, Room 171, York Hous Kingsway, London, W.C.2, quoting F56/47A.

LECTURER IN PHYSIOLOGY AND ZOOLOGY—The Registrar, Technic College, Sunderland.

INCENTIVES IN MANAGEMENT AND PRODUCTION

ALTHOUGH in his speech at the outset of the debate in March in the House of Commons on the economic situation in Great Britain, Sir Stafford Cripps emphasized the importance of the necessity for some incentive element, throughout the wages structure, which would be an inducement to a higher rate of productivity, and elaborated further the policy foreshadowed in the White Paper in that respect, the Budget proposals showed little evidence of the Government's intention to implement that policy. The debate on the economic situation tended to concentrate attention on this question of incentives, and on that of securing the most effective distribution of man-power. Mr. Lyttleton brought strong support to Sir Stafford Cripps' observations on the importance of incentives, and Wing-Commander Millington's example of the increase in output of bricklayers from 80 bricks to 462 bricks per man per day as a result of incentive schemes shows what can be done by the introduction of incentive schemes into wage systems.

The vital bearing of both these factors on the industrial and commercial efficiency, on which, as Sir Andrew Duncan rightly said, rising standards of living, increased leisure and social security all depend, was fully displayed in the debate, although the significance of the Prime Minister's remarks about mixed incentives was passed over. Doctrinaires on either side will do real harm by attempting to exclude either the public or private interest motives. Few men and women are not influenced both by the idea of public service and by private profit, and which incentive is the more effective will depend on circumstances, and on the type of person. What needs to be remembered is that the question of incentives is not restricted to one particular class: it is as important among the professional and managerial class of workers as among the manual workers. While, however, the importance of efficient management is now widely recognized, the question of management incentives has received nothing like its proper attention. It is fully as important as that of the wisest distribution of our resources in administrative ability, over which such concern was expressed in the House of Commons debate on man-power on March 19.

Taking the brain-power of Great Britain as a whole, we have to do two things. On one hand, we have to see that it is deployed to the best advantage—that neither the Armed Services nor the Civil Service are allowed to draw excessively on the limited resources of trained man-power, scientific or otherwise, leaving the universities each year, and that within the Services as in industry those resources are fruitfully and fully employed. On the other hand, we have to see that the conditions of service are such as to stimulate those men and women to exert to the utmost the abilities which they possess.

It is realized that the allocation of technical knowledge between the competing demands of defence, industry, medical research, etc., is no simple task. Even a system of priorities demands constant scrutiny and revision, and only incessant vigilance can eliminate waste even if man-power has been allocated in accordance with the most rigorous and satisfactory scheme of priorities. Moreover, the debate on defence on March 20 gave rise to some uneasiness that in certain fields the distribution of trained man-power is out of balance.

In a speech in the defence debate on March 19, Mr. A. V. Alexander announced that during the coming year some £60 millions would be spent by the Admiralty and the Ministry of Supply in scientific research and development. He had already, in the debate on the economic situation in Britain, indicated that, of the man-power in the Armed Forces, some 46,000–47,000 were engaged in such work. The estimated expenditure of £3,118,000 of the Department of Scientific and Industrial Research includes some for military purposes, and the grants to universities and agricultural colleges and institutes include large sums for maintenance and teaching costs and the usual apparatus of student life; hence *The Economist* is probably not far wrong in its estimate that out of an anticipated expenditure of slightly less than £19 millions for research during 1947–48, including that on the Agricultural and Medical Research Councils, Colonial research, the universities, and research financed directly by the Department of Agriculture and Fisheries, only some £10 millions is used for research proper.

The contrast between this £10 millions and Mr. Alexander's £60 millions is striking, even when we bear in mind that the figures do not include the unknown but considerable expenditure of private industry on research. But whether the comparison is by expenditure or by man-power, the picture seems out of balance, and however readily it may be possible to justify the expenditure on military research—and the stress laid in the defence debates on the importance of scientific development and research is a welcome and reassuring feature—it at least appears probable that the economic position of Britain makes further assistance necessary from the Exchequer for research in fields bearing on industrial development. Mr. Alexander stated that the Defence Research Policy Committee and the Advisory Council on Scientific Policy would be in general control of policy and priorities, and would concentrate their energy on stimulating research in fundamentally new fields which scientific discoveries have opened up. On the picture thus presented, they will need to grapple more seriously with the distribution of the country's scientific man-power and material resources than the Government has yet attempted to do. It is at least a sound reason for Sir Henry Tizard's tenure of the chairmanship of both bodies.

The distribution or redistribution of man-power in any field is admittedly a difficult problem; but despite the attention focused upon it in recent debates, few constructive proposals have been forthcoming either from the Government or the Opposition. Reliance appears to be placed in the main upon incentives, and although the operation of a system of incentives either as a factor in attracting man-power or brain-power where the interests of the nation most require them, or in increasing output, is handicapped by shortages of raw materials, equipment and labour, the importance of incentives is not easily over-stressed. For all that, Mr. R. A. Butler appears to have been alone in the recent debate on the economic situation in stressing the importance of incentives for the management and others in industry as well as for the manual workers.

The point has not entirely escaped Political and Economical Planning, which in a recent broadsheet "Men, Management and Machines", pointed out that first-class management will not be obtained while every manager is liable to indiscriminate politica denigration. The psychological factors are in fact even more important than the financial incentives for the manager, and also for the research worker and an interesting little note "The Requirements for Fruitful Research" printed in a recent issue of the *Journal of Chemical Education* (24, 165; 1947) is rather marred by its failure to recognize this. In this article a distinction is drawn between the worker in pure science and the worker in applied science and the investigator in applied science is designated interpreter.

The distinction between pure and applied research is much less clear-cut than is suggested in this note though it is rightly urged that the function of the applied research worker is "to deliver the goods", and that industry will judge his success by the measure in which his work leads to practical results. Few research managements, however, would to-day agree that adequate material rewards alone would suffice to attract the best men in adequate numbers Individual rather than mass psychology is also important, and for fruitful industrial research th atmosphere and conditions of work are little less important than in fundamental research in the university. The atmosphere of freedom matters, too even if there must in the nature of things be restraint that do not, and should not, apply in the university where fundamental research finds its natural home

What is overlooked in this little note is the interaction between the university and industry. If it important that a university should rigidly guard its freedom and abstain from entering the field of applied research, it is equally important that condition within the university and within industry should b such as to foster the free and full exchange both staff and of knowledge. Neither will benefit from disparities in conditions of service, financial or otherwise, which denude one or the other of a prope proportion of the highest type of ability it need One of the greatest problems facing Great Britain in fact to provide in industry and in the publ service conditions which stimulate to the highe degree the creative thought, the enterprise an adventurousness which mark the ideal investigat at the university seeking to extend the bounds human knowledge.

That indeed is the position taken up by Mr. W. Wiegand, director of research of the Columbia Carbon Co., in a paper, "Motivation in Research" in *Chemical and Engineering News* of October 25, 1946. Mr. Wiegand emphasizes the complex character of motives or incentives in research, and observes that it is a mark of true insight to foster and encourage the adventurous phase of research. The competitive spirit, he holds, cannot be ignored, and need not be discouraged. Mr. Wiegand recognizes the value of a generous publication policy and of taking care to ensure that individual recognition is forthcoming for good work; but however careful we may be to establish the right conditions of service, the spark of leadership will always be indispensable for the most fruitful results. Motives and emotion are indivisible; and a friendly, loyal and appreciative management is as vital a factor in research as it is in the handling of men in production or distribution, and one which no elaborate equipment or careful organisation can displace. Indeed, the very fact that industrial research depends so much upon teamwork enhances the importance of leadership in this sense as contrasted with the direction of research.

The point was well brought out by Mr. L. C. Gabriel in his chairman's address to the Road and Building Materials Group of the Society of Chemical Industry last year. Industrial research must obviously conform to a long-term predetermined plan, and the leader of any research team must exercise mental discipline to ensure a proper relation between achievement and the agreed plan. Much latitude in detail must be allowed to all responsible staff, and the control from above must seek essentially to promote a voluntary discipline to prevent helpless drift and to turn individual enthusiasm into profitable channels.

Such psychological factors are more important than the physical conditions of work. This is not to deny that a research team works most fruitfully in a modern well-equipped laboratory, with pleasant surroundings, facilities for reading and writing and for formal and informal discussion, nor to suggest that there are not many industrial and indeed academic laboratories which fall far short of any reasonable standard in this respect. But it is well to remember that, in research as much as in industry at large, there is a factor of management or leadership which is indispensable to enable our objectives in research or in production to be attained; no organisation, on the national scale or in the laboratory itself, which disregards this factor can hope to succeed or to secure that higher standard of productivity and greater output upon which national recovery depends.

From this point of view the problem is similar whether we approach it from the aspect of labour or from that of research. The manager or administrator has to take account increasingly of the human factor and to devise the conditions of work and the incentives which will induce men and women willingly to give of their best. In so far as nationalization of an industry promotes such an atmosphere of co-operation—as is probably true in the coal industry—it is *a priori* to be welcomed, provided there are not other factors in nationalization which militate against efficiency. It must be borne in mind that so far there has been little evidence that the public corporation provides the conditions of service or the incentives which stimulate enterprise, initiative and first-class efficiency in the administrator in quite the same way as the best concerns in private industry.

It has already been suggested that this may well be our biggest problem. It is admittedly difficult and complex, but there are new opportunities opening up before us, and new instruments being created which may be used to find the way to a solution. It is one to which the National Coal Board may rightly be expected to give some consideration, and it is pre-eminently one for consideration and study by the new British Institute of Management and the Administrative Staff College. Other bodies too, such as the Institute of Industrial Administration and the National Institute of Industrial Psychology, have contributions to make, and the trade unions themselves could help if they were minded to take a more positive and constructive view of their functions. Bonus schemes and other financial incentives for the research worker and manager might well be re-examined objectively by such bodies; but much more is required. The creation of the right atmosphere and conditions of co-operation, and the discovery of the organisation and intelligence system which industry and society need to meet the increasingly complex demands of to-day, require co-operation from many quarters, and above all in the same spirit of impartial patient searching for truth which animates the research worker in his own laboratory investigations. Moreover, the growing importance, if not necessity, of a scientific approach to labour problems, as urged by Mr. W. C. Puckey in a stimulating paper before the Royal Society of Arts on January 29, with all that such an approach connotes, in training for management and in a scientific outlook on the part of the manager, emphasizes once more the necessity of a considered attempt to ensure that the administrator, no less than the research worker, is both adequately trained for his job and also given the essential conditions for doing it.

INDIA AS A SOCIAL KALEIDOSCOPE

Caste in India

Its Nature, Function and Origins. By Dr. J. H. Hutton. Pp. viii+279. (Cambridge: At the University Press, 1946.) 18*s*. net.

THIS 'brief conspectus' is for students, and assumes in its readers some knowledge of India and anthropology. Dr. Hutton claims no novelty, and draws freely on the accounts of Blunt and O'Malley (1931–32) and on his own Census Report of 1931, two important extracts from which, on 'untouchables' and on primitive religion, are reproduced *in extenso* as appendixes.

The ground is covered in three sections, each of four chapters. Part 1, "The Background", after a rapid glance at the races and languages of India, gives a short account, province by province, of such castes and tribes as illustrate the "almost incredible diversity" of Indian society. Part 2, "Caste", is concerned with (1) "Structure", the interaction of marriage restraints and social status, and safeguards against *mésalliance*; (2) "Strictures" on food and drink, on custom and occupation; (3) "Sanctions", caste councils and other controls, the offences they try, their procedure, oaths, ordeals and penalties; (4) "Functions", the effect of caste for good or ill on the individual, the community, the State and society generally. Part 3, "Origins", discusses (1) institutions analogous to caste in other civilizations; (2) the traditional origins of caste in India (mostly from Chapters 6 and 12 of Dr. Hutton's Census Report of 1931); (3) theories of modern writers, and (4) conclusions drawn from the evidence.

All this is familiar; but the picture differs sharply from that drawn by nineteenth-century scholars, who, on the evidence of Sanskrit scriptures, traced caste (and civilization generally) to 'Aryan' invaders. But 'Aryan' culture as depicted in the Rigveda has little in common with Hinduism. Later research has revealed abundant evidence of elements typical of Hinduism in the pre-Vedic civilization of the Indus Valley cities and in the beliefs and practices of non-Aryan castes and tribes. The sources of Indian society and religion lie deeper and wider than the Sanskritists supposed. Presumably Rigvedic culture was absorbed into a strongly established indigenous culture of far older date.

The elaborate restrictions on marriage in India, the most prominent feature of the caste system, Dr. Hutton suggests may partly be due to "the impact of patrilineal invaders on an indigenous matrilineal population", and infers from good evidence that matrilineal descent, which still flourishes on the west coast, was at one time widely distributed throughout India. On these lines he would explain the prevalence of hypergamy, cross-cousin marriage, pre-puberty marriage, purdah and temple prostitutes.

Restraints on 'interdining', on the giving or taking of food and water, as well as pollution by touch, he ascribes to ideas of magic, mana, 'soul-stuff', life matter, etc., conveniently grouped as 'power' (p. 202), a sort of dangerous energy inherent in certain persons and things, the operation of which Sir James Frazer has aptly compared with that of electricity, which not so long ago was called a 'fluid'. Such taboos are common to all humanity, civilized as well as primitive; they have a practical value in a country where the population of a village may be decimated in a night by cholera, and vermin-borne disease may devastate the homes of 'untouchables', leaving their cleanlier high-caste neighbours unharmed.

Another big factor in shaping caste is the caste council. Each caste claims to discipline its own members. Brahman influence is indirect; Brahmans set standards of 'correct' behaviour and purity, and can withdraw their services in the ceremonies associated with birth, marriage and death in other communities, but they have no decisive authority in matters of caste. In early India such authority was vested in the king, and it still survives in many Indian principalities; but State jurisdiction is mainly appellate and adjusts disputes between caste and caste. The initiative in framing caste law and rules of conduct (*dharma*), the right to expel or re-admit, lie within the caste. The constitution and working of caste councils present every conceivable variety, and it is significant that the lower the caste in the social scale the stronger the organisation for regulating its own affairs, and it is strongest in tribes outside the pale of Hinduism. Obviously caste autonomy was neither invented by Brahmans nor imposed by State decree.

In assessing the merits of caste, Dr. Hutton stresses its value as a bond of union in a 'plural society', by which a multitude of disparate communities are welded into a social whole, yet retain each its own character and way of life; and he contrasts the 'stability' of caste from time immemorial with the warring nationalities of Europe and the colour problems of Africa and America.

Caste, in short, is an 'organic' growth, the product of many factors interacting within India over a long period of time, factors well known outside India; but, as Dr. Hutton observes in reviewing "analogous institutions", nowhere but in India do they produce a caste system. Moreover, like living organisms, the system is in perpetual flux, and has been so from time immemorial, constantly adjusting itself to changes in environment, ethical, economic, religious and so forth, new castes splitting off from old castes, and old castes rising or falling in the social scale; so mutable is it that no account of it can remain accurate for long. Criticizing not ungenerously the views of previous writers, Dr. Hutton deprecates approach from "a single view point", and makes no attempt to define the indefinable. Instead, he concludes with a list of the more obvious factors which have made caste what it is.

This compact essay should serve its purpose well. References are given in footnotes wherever needed; bibliography, glossary and index are excellent, and the student can thread his way easily through the haze of fact and fiction that surrounds caste.

F. J. RICHARDS

PRACTICAL FRUIT-GROWING

Fruit Growing Outdoors

By Raymond Bush. Pp. 518+105 plates. (London: Faber and Faber, Ltd., 1946.) 18*s*. net.

THE ready sale of Raymond Bush's Penguin Series of booklets on fruit-growing demonstrates the keen demand that exists to-day for sound advice on gardening topics, especially when presented in the easily assimilated form that characterizes the writings of Mr. Bush. The fact that here and there the expert can detect partial truths or inaccuracies detracts little from the general usefulness of the advice to the practical man, and provides the more knowledgeable man with opportunities for delighting himself in finding Mr. Bush at fault. No claim is made that the books are based on research findings, and it is obvious that they are not; but where it has suited the author he has made use of proved facts, and where it has not suited him, or where such facts are lacking, he has inserted his fancies with equal weight. Actually, his advice is very sound on the whole, as he is speaking about things with which he is thoroughly familiar after a lifetime of fruit-growing, for some years commercially and more recently as an amateur.

While the Penguin booklets are admirable for reading on a journey or carrying in the pocket, they lack the permanent binding and presentation that is needed for a book that will be used for constant reference. There can be no doubt, therefore, that the publication of these fruit-growing booklets in a single volume will meet with general approval. Messrs. Faber and Faber have made the thorough job that one expects of them—clear, readable type nicely arranged on good paper, the whole being tastefully bound in a handy-sized volume, though more care in proof reading might have avoided the many small errors that occur in both text and index.

Reprinting of this nature, however, raises problems, some of which have not been very happily solved in this case. Two courses of action seem legitimate: either the separate parts reprinted in one volume should preserve the original matter intact, or if revision is permitted it should be thorough. While the first course is the simplest, the latter course has obvious advantages for the reader, and the scale of the present reprinting would have made such revision an easy matter. Mr. Bush has, however, adopted an intermediate course, making enough changes to lull the reader into a false feeling of up-to-dateness while leaving unaltered many other equally simple alterations. Thus, while "Lebensraum" becomes in a de-Nazified world "Elbowroom" (p. 337), and "Sir William Beveridge's" plans become "Socialist" ones (p. 222) with the change of Government, no reference is made of the valuable supplement to T. Wallace's "Diagnosis of Mineral Deficiencies" in the footnote on p. 94, where the original publication is mentioned. Reference is still made to a grafting booklet (p. 42), by R. J. Garner, that has been out of print for eighteen months or more, and the price is some three years out of date. The spraying chart remains untouched by recent knowledge, and stirrup pumps would seem to be still occasionally used for incendiary bombs (p. 183). The opening paragraph of Chapter 3 refers to the small space at the disposal of Mr. Bush in contrast to that in Mr. Bagenal's "Fruit-growing"; while this was true of one volume of the Penguin series, Mr. Bush's omnibus volume contains 496 pages in contrast to Mr. Bagenal's 416 pages!

The original illustrations have all been carefully re-drawn for this edition. The artist has made good use of the better facilities for reproduction afforded by this book, and the general effect is cleaner and neater. The result might have been better still if the artist had drawn direct from Nature instead of faithfully copying Mr. Bush, as he was not always quite correct in the original. For example, in Fig. 4 the bud looks quite unlike an apple bud, and the slit to accommodate it is inconveniently short. More care is needed in checking with the text those figures that have been altered; typical discrepancies occur with Figs. 64 and 65 and p. 362, where the footnote is no longer needed, Fig. 37 and description on p. 207, and p. 472 where the figure referred to does not appear.

The chief addition to the original volumes is the fine collection of plates. Few books of this nature are so well illustrated. Other valuable additions are line drawings of the chief insect pests, a section on renovating old trees, another on growing bush peaches and brief references to D.D.T. and the artificial setting of tomatoes. It is difficult to see why Section 3 was honoured by a re-written introduction when the fact that the original introduction was no longer suitable might have been seized on to omit it altogether, thus assisting the unification of the parts. It is surprising that it was considered necessary to number the chapters in parts since the pages are consecutively numbered right through, and the present arrangement leads to awkward cross-references in the text.

Considered as a handbook on fruit-growing, the arrangement could be much improved. It is disconcerting, for example, to find the subject of planning a fruit garden dealt with piecemeal in each of the three parts, with certain overlapping. The same is true of spraying. The chapter on books would be more appropriate at the end, and the important subject of spring frosts might have appeared nearer the beginning. The presence of chapters on nuts, mushrooms and tomatoes in the Soft Fruit Section seems scarcely justified. Naturally, one must accept this arrangement in an omnibus volume, but it is a pity Mr. Bush did not spare time to rearrange or rewrite the original Penguin booklets into a carefully planned manual covering the whole field of fruit-growing.

There is little doubt, however, that "Fruit Growing Outdoors" will find an honourable place on the bookshelves of keen amateurs, professional fruit-growers and even hardened research workers.

H. B. S. Montgomery

BREEDING OF FARM ANIMALS

The Breeding of Farm Animals

By Chapman Pincher. (Penguin Handbooks, PH.10.) Pp. 150+7 plates. (Harmondsworth and New York: Penguin Books, Ltd., 1946.) 1*s.* net.

ATTEMPTS at popular exposition of the scientific principles of farm livestock breeding have usually been made by those who have worked in one or other of the many fields of study which make up this 'practical' subject. No doubt, it is because of the intricacy of the considerations involved that the authors usually refrain from too sweeping or dogmatic statements, although they must recognize that their efforts to meet popular approval and appreciation are thereby weakened. Here, a fresh attempt to get some of the newer knowledge across to the practical man is made by an author whose name is hitherto unfamiliar in this particular connexion. Mr. Pincher brings his journalistic experience into action, and traverses reproduction, genetics, breeding policies, beliefs, and practical problems in pursuit of his objective.

He apologizes to professional biologists for certain conscious sacrifices to clarity in his treatment of the reproductive processes. But it must be confessed that this apology in itself raises doubts as to the origin of his lack of clarity and precision in other aspects of the general topic. His compilation of facts and his interpretations are open to criticism from men of science and practical men alike. As examples, from the many: few geneticists would agree that "The only test for the purity of a dominant character in a beast is to cross it with another animal known to be impure for that character", or that the F_2 ratio for a single pair of genes, with dominance, is 1 : 3 : 1; both groups of people would doubt the implication that true hermaphrodites are common in poultry flocks; and most sheep-breeders would object to the Black Welsh being included if the main breeds of mountain sheep were to be restricted to six.

The author has made a courageous attempt to expound principles usually considered applicable; but commendation is withheld for two main reasons. First, the numerous blemishes could easily have been removed without much effect on the content or the style of the book. Secondly, as at best such a text could only serve as an introduction to the subject, and not be entirely authoritative in itself, a general bibliography or selected references should have been given.

J. E. Nichols

SPONTANEOUS COMBUSTION OF HAY

By Dr. J. B. FIRTH and Dr. R. E. STUCKEY
Home Office Laboratory, Preston

THE self-heating of hay has long been a subject on which many conflicting theories have been put forward. Our recent work[1,2] has provided data which may perhaps help to give a clearer understanding of the processes preceding spontaneous combustion.

Early Theories

A number of the theories put forward were undoubtedly influenced by the prevailing chemical concept of the day. There were, for example, theories put forward dependent on the pyrophoric properties of certain elements, notably carbon, iron and manganese, when in a finely divided condition. Thus, Buckner[3] in 1872 introduced a theory centring about the idea of pyrophoric carbon and its absorptive power for atmospheric oxygen. Ranke[4] in 1873 made a detailed examination of a heated stack and was probably the first to describe hay which, when forked out, sparked and burst into flames. This phenomenon was held to support the pyrophoric carbon theory, and the attainment of the high temperature necessary for pyrophoric carbon formation was attributed to the insulating properties of the hay.

The stumbling block in these theories was the question of how the hay could arrive at such a high temperature, and to overcome this difficulty Miehe[5] (1907) put forward his low-temperature carbonization theory. In this it was assumed that the temperature was taken to 70° C. by thermophilic micro-organisms and never rose above 70°–80° C., a slow carbonization taking place. The interaction of the fine carbon produced and atmospheric oxygen caused the final ignition. This theory, however, has since been proved to be untenable, as James and Price[6] have reported fires due to spontaneous combustion which occurred in less than five days from the wetting (due to floods) of hay.

Boekhout and de Vries[7] considered that ionized iron in the cell sap had a catalytic action, while Laupper[8] held pyrophoric iron and not pyrophoric carbon to be responsible. The latter investigator worked out an extensive scheme showing products at various stages in a stack, introducing at the final stage pyrophoric manganese. There can be little doubt that in the later stages of the heating, pyrophoric carbon will be produced; but this is probably true of the prolonged heating at high temperatures, in the absence of air, of any similar organic material. The point is that the pyrophoric substances are only secondary in action and have no bearing on the main cause of the heating.

Another phase of theories was originated by Tschirch[9], who strongly criticized Miehe's low-temperature carbonization theory, advancing the view that not bacteria but oxidase enzymes were responsible, through production of oxygen which was 'pent up' and caused rapid oxidation and heat. Burri[10], modifying this, postulated heat-resisting enzymes, though later Hildebrandt[11] concluded from experiments that enzymes could not be responsible, and criticized the theory of Tschirch. Hildebrandt reverted to the assumption of the activity of micro-organisms as an explanation.

These theories are open to criticism mainly on the grounds that although certain experiments were carried out in their support, conclusions were drawn on evidence which was not related to the intermediate and end-products of self-heating actually present in a stack. This drawback probably originates in the difficulty of observing stacks which have undergone spontaneous combustion. Investigation of numerous stack fires during the war years (more than a hundred and fifty fires have been examined, including fifty samples of self-heated hay at all stages of development and heating) has given us opportunities of examining and trying to explain the processes occurring.

Certain fundamental facts are available on which any explanation can rely. Cohn[12] (1890) showed that approximately 40° C. was the highest temperature reached by means of ordinary plant respiration, but there was a further rise to 70° C., possibly due to thermophilic micro-organisms. Miehe (*loc. cit.*) isolated numerous organisms and named *B. calfactor* as being responsible. The work of Haldane and Makgill[13] also supplied evidence in support of this.

Browne's Theory

Browne[14] (1929), in an excellent review of the subject, made the first real attempt to put forward a logical explanation of the self-heating in the decomposition of substances by micro-organisms, followed by a chemical effect producing the breakdown of sugars in the presence of ammonia—a number of reports having mentioned the odour of ammonia around a stack.

According to this view, there was no difference in the mechanism of the heat production between 50° and 70° and above 70°, the heat being due in both cases purely to chemical causes. Browne states: "In other words the micro-organisms simply produce the highly unstable compounds whose subsequent oxidation . . . generates the increasing quantities of heat that lead first to the destruction of the organisms themselves and then eventually to the ignition of the hay". This theory was held to be supported by experiments showing the production of unstable unsaturated compounds from sugar by the action of lime.

Browne adds: ". . . the foregoing explanation of the spontaneous combustion of hay may be criticized on the grounds that there is no evidence for the existence of such highly unstable intermediary compounds as this hypothesis requires".

A New Approach

In our opinion the theory of Browne is essentially true. We have, however, never found a stack, heated or not, which was alkaline in reaction. All were slightly acid, and the spontaneously heated stacks very strongly so. Ammonia is probably present at some stages from protein breakdown; but we have not actually encountered it, and it is certainly not present to such an extent as to cause carbohydrate breakdown in alkaline medium.

Our preliminary work[1] showed certain features of a self-heated stack, chiefly (in a chemical sense) the gradual development of an acidity which was at a maximum in dark brown hay before such hay had reached the actual temperature of carbonization and destruction of products. Stacks showed in general two effects of spontaneous combustion; in one of these there was a large, central, heated portion with general conflagration and no visible 'flues'; in another, the heated portions were more distinct and a number of 'flues' were shown which smoked and smouldered although the stack might not actually be burning.

Further work[2] on the chemical constitution of the acidity showed that the non-volatile fraction consisted of lactic, malic and succinic acids, while the volatile acids acetic and formic were also present. Lactic and acetic acids predominated. The total acidity was up to 8–9 per cent calculated as lactic acid on the dry matter, and a number of samples analysed later contained as much as 12 per cent. Since acetic acid, the main volatile acid, is present, it is very probable that the real acidity was much higher than actually found, volatile acid being lost in the heating process.

Considerable loss of volatile acidity is in fact unavoidable, and it is noteworthy that in cases where the stack was specially cut for us, and samples were taken from inside and immediately transferred to air-tight containers, the acidity was of a higher order and the volatile acidity proportionately greater.

It is obvious that the production of acidity is a big factor, and almost certainly the main factor, in self-heating, and that any satisfactory theory must take this into account. It is also clear the acidity is derived from carbohydrate breakdown.

The examination of the type of acidity gave, in our opinion, a very definite lead to the processes taking place. Typical results were as follows:

	1	2	3	4
Volatile acidity calculated as acetic acid percentage on dry hay	1·51	1·20	1·17	0·36
Residual acidity calculated as lactic acid percentage on dry hay	5·33	4·32	4·81	2·37

This shows good agreement with the acidity present in silage of higher acid values. Watson[15] quotes the following analysis of ordinary silage of varying *p*H values:

	1	2	3
Volatile acids calculated as acetic acid percentage on dry hay	3·21	2·91	4·01
Residual acidity calculated as lactic acid percentage on dry hay	8·44	4·33	2·60

Figures are rather variable, and obviously in such a complex and cumulative action as carbohydrate breakdown even a slight variation in conditions may lead to big variation in the resulting products.

The composition of the acidity of silage determined earlier by Annett and Russell[16] was remarkably similar to that found for self-heated hay. Thus, Annett and Russell found that the fixed acidity contained lactic, malic and succinic acids; the volatile acidity contained acetic and formic acids. The striking similarity between the composition of silage and self-heated hay indicated that a study of the processes occurring in silage would most probably provide the answer to the problem of the haystack.

In silage the crop is alive in the silo and for the first stage is actively respiring, aerobic changes taking place while the air in the herbage is used up. When this occurs, the second stage starts and intracellular respiration or fermentation takes place. The cells die, and micro-organisms begin to multiply, using as a medium the contents of the dead cells. The chief changes in the silo consist of the breakdown of the carbohydrates with the production of carbon dioxide, alcohol, and organic acids including acetic and lactic acids. Proteins are also broken down, though this may, perhaps, be an action secondary in importance so far as spontaneous heating is concerned. The exclusion of air, either partial or total, is necessary for the proper production and preservation of silage. The temperature of the mass usually rises, varying with the efficiency of exclusion of air.

In the silo, conditions are such that there is a plentiful supply of moisture but a limited and finally negligible amount of air. If air were admitted freely during the operation, a high temperature would result, and presumably spontaneous combustion would finally take place just as in the case of moist hay. In stack silage where exclusion of air is difficult, temperatures are high.

Suggested Actions Occurring in a Stack

In an ordinary well-made, well-dried haystack, there is a supply of air in the centre—not abundant, but sufficient. Some respiration occurs, the amount depending on the extent to which the drying process has killed the cells, and this is followed by the second stage, namely, microbiological action with the production of some breakdown products and acidity. This action is very slight in the ordinary, normal stack, but occurs further in the production of 'brown hay', popular on the Continent, with temperature rising often to 90° C., together with some caramelization of sugars. Fairly early, however, in a normal stack, a stage is reached when the amount of water is insufficient to allow further growth of micro-organisms, activity slows down and the stack cools off. Here *water* is the limiting factor preventing the continued growth of the micro-organisms.

In the case of hay which is undergoing spontaneous combustion, there is sufficient moisture present to allow further changes in the silage cycle, and the temperature rises rapidly if air is present to any extent (note that after flooding in Vermont, U.S.A., stacks 'fired' in four days). Carbohydrates are decomposed by micro-organisms to produce, for example, lactic and acetic acids from unstable intermediate oxidation and breakdown products. The porous structure of the hay helps in the process, and oxygen is absorbed from the air, oxidation occurring at points of molecular unsaturation with the production of heat. It is commonly known (cf., for example, J. Thompson[14]) and has been confirmed by us in the investigation of linseed oil-waste fires that the products of oxidation strongly catalyse the oxidation itself; that is, the process is autocatalytic. In addition, it is found that 40° C. is a critical point in the self-heating of waste contaminated with unsaturated oils. Above this temperature, spontaneous heating is much accelerated, and by raising the temperature to 40° C. combustion can be started in many materials which would otherwise not ignite.

Above 40° C., therefore, heat is being developed in the hay at an increasing rate. Towards 100° C., water is driven off to outer layers and we get a change, in that the reaction is taking place for the first time in comparatively dry medium. Earlier in the cycle, water was a limiting factor, curtailing the growth of micro-organisms; lack of oxygen now becomes the limiting factor until the decomposition, often following the path of hot gases produced, reaches the outside of the stack. There the excess of oxygen produces enough heat to cause fire.

The processes occurring in wet hay, ordinary normal hay and silage are summarized below.

Self-heated Hay.

(1) Respiration takes place causing the initial rise in temperature. The amount of respiration depends on the extent to which the plant cells have been killed in the drying process.

(2) Micro-organisms develop rapidly in the presence of moisture and with the rise in temperature, attacking the cell sap constituents and initiating decomposition.

(3) Rise in temperature up to *c.* 40° C. kills plant cells and respiration ceases. Some thermophilic micro-organisms may continue to be active above 40° C. Sufficient water and air are present to allow growth to continue. Breakdown of carbohydrates produces unsaturated compounds which are oxidized and partly hydrolysed with the production of heat.

(4) At temperatures above 40° C. the micro-organisms are gradually killed off by the temperature. *The decomposition products are then sufficient in amount to catalyse further decomposition of carbohydrates.* The increased temperature gives a greatly increased rate of oxidation of unsaturated compounds, as shown experimentally for unsaturated fatty oils.

(5) At 100° water is driven off from the heating centre, and oxidation and hydrolysis are replaced by oxidation with production of more heat. The limiting factor now is the amount of air present.

(6) The rate of chemical reaction increases sharply until the surrounding hay is charred and access to air is gained. Here, the plentiful supply of oxygen gives heat which cannot be conducted away, and ignition occurs.

Ordinary Hay.

(1) Some respiration takes place causing rise in temperature, the extent depending, as with self-heated hay, on the extent to which the plant cells have been killed in the drying process.

(2) Micro-organisms develop with rise in temperature, attacking cell constituents. Decomposition is slight, *the growth of the organisms being limited by the lack of water.*

(3) Decomposition is insufficient to set up the autocatalytic reactions, and the stack cools off.

Silage.

(1) Respiration takes place until all oxygen is used up or replaced by carbon dioxide.

(2) Micro-organisms develop and operate in the absence of air. The limiting factor here is the lack of air, and the interior of the silo cools off. Breakdown products of carbohydrates are produced; but there is insufficient air for any extensive oxidation to take place, and the heat developed is small in comparison with wet hay.

THE CULTIVATION OF A THERMODYNAMIC OUTLOOK

THE place of thermodynamics in education was recently discussed by the Low-Temperature Group of the Physical Society. In outlining the purpose of the discussion, the chairman, Sir Alfred Egerton, explained that a feeling exists among members of the Group that the thermodynamics teaching given to students in Great Britain is often inadequate; and it was in the hope of formulating constructive proposals for its improvement that this meeting was called. He added that it was not his intention to confine discussion only to low-temperature aspects of thermodynamics, but to encourage discussion over the whole thermodynamic field.

Opening the discussion, Sir Charles Darwin pointed out the difference between the teaching of mechanics and of thermodynamics in Britain. On one hand, in the teaching of mechanics, the student is drilled to solve numerous examples until all the implications of Newton's Laws have been driven home. On the other hand, thermodynamics is often introduced in abstract terms and clothed in a maze of algebraic symbols, thereby leaving the student confused in his conception of the subject and ill-equipped to apply such thermodynamic knowledge as he has gained to new problems. Sir Charles thinks thermodynamics is a harder subject than mechanics, but not much harder.

Elementary teaching of thermodynamics in the past has been confined almost entirely to gases and liquids, and this has tended to obscure the generality of the subject. Also in setting examination questions too much demand has been made for the mathematical manipulations involved in getting, for example, from C_p to C_v. Now that the new fields of magnetism and the elasticity of rubber have been opened, other examples are available, and the teaching of thermodynamics can be widened in its outlook. Exercises in spotting the fallacies in perpetual motion machines also provide a useful field of instruction. The use of numerical examples should be extended, for only so can experience be gained of the relative importance of the various factors in a process.

In conclusion, Sir Charles Darwin posed three questions, to which he supplied his own tentative answers:

(1) Should thermodynamics play a greater part in education ?

(2) At what stage, school or university, should it begin ?

(3) Should statistical theory come in ?

To the first question he gave an affirmative answer. In answer to the second question he considers that a start should be made at school about two years after mechanics, but to be suitable for schools the text-books will need to be re-shaped. Regarding the third question, he favours withholding statistical theory, except for a few descriptive examples which call for no mathematics.

The next speaker, Prof. E. A. Guggenheim, stated his convictions that the number of people in the world who thoroughly understand thermodynamics in all its aspects is well under a hundred, and the number in Great Britain is certainly in single figures. He said, however, that he is less disturbed by these small numbers than by the degree of ignorance of thermodynamics by the remainder of physicists, chemists and engineers. Unfortunately, this includes people whose task it is to teach thermodynamics and to abstract papers on this subject. A symptom and, at the same time, a cause of this state of affairs is the failure to afford to thermodynamics its true significance and status by confusing it with the experimental techniques of thermometry and calorimetry, and the largely empirical laws of heat transfer, under the general title of 'Heat'.

Thermodynamics, he said, has a bearing on almost every branch of physics and particularly on mechanics, hydrodynamics, electrostatics, capillarity and chemistry. In these subjects many of the laws and formulæ taught are defined only under the condition of constant temperature—for example, Hooke's Law, Ohm's Law and Boyle's Law. As soon as one inquires into the effects of varying the temperature, one enters the domain of thermodynamics. This has led to much confusion in the use of the word 'energy' in such expressions as the 'energy of a coiled spring', or the 'energy of a charged condenser'. Here the quantity cited is usually the free energy, and the total energy is a more complicated quantity, since it is to be noticed that the performance of work at constant temperature is, in general, accompanied by a simultaneous absorption or emission of heat.

Prof. Guggenheim recommended that students, immediately after learning mechanics, should be made familiar with :

(1) the existence of temperature ;
(2) the conservation of energy ;
(3) the correct definition of heat ; and
(4) the distinction between actual and reversible processes.

The quantitative relationships between work and heat can best be introduced in particular examples, such as coiled springs, compressed fluids and charged condensers, as these subjects in turn come up. Only at a later stage is it necessary to stress that all such relations are particular examples of the general laws of thermodynamics.

Prof. D. M. Newitt, speaking of the bearing of thermodynamics on chemical engineering, stated that the aim of chemical engineering is to co-ordinate a series of elementary physical operations and chemical processes in such a way as to bring about economically some desired change of state or composition in a given system. It therefore requires equally a knowledge of thermodynamics and molecular physics. He considers it desirable that the teaching of statistical mechanics and the kinetic theory should run parallel with and not follow a course in thermodynamics since, in general, chemical engineering problems are concerned not only with the driving force necessary to bring about a specified change, but also with the rate at which that change can be made to take place.

Attention was directed by Prof. Newitt to the present unfortunate divergence, both of approach and of emphasis, in the teaching of thermodynamics to physical chemists on one hand, and engineers on the other. Thus the chemical engineer, who receives tuition in both schools, is liable to unnecessary confusion. The wide variation of notation between different text-books of both subjects has also added to the confusion. Prof. Newitt voiced the plea that uniformity of notation should be adopted in the teaching of thermodynamics. In conclusion, he suggested that more use might be made of graphical and geometrical representation in the teaching of thermodynamics. Exercises in the construction of such diagrams and models might well make up for the paucity of laboratory experiments for illustrating thermodynamic principles.

Mr. A. M. Clark said that, although a complete knowledge of thermodynamics may be restricted to a few, an understanding of the principles involved is important for all scientific workers, irrespective of the particular branch of the subject chosen for specialization. He considers that the first and second laws of thermodynamics are even more fundamental and more rigid than the basic laws of chemistry and mechanics, such as the laws of conservation of mass and Newton's Laws of Motion. The student should be introduced to them at the earliest possible stage, that is to say, at the same time as he learns to appreciate the other fundamental laws. For this purpose the early teaching of thermodynamics should be divested of advanced mathematics and complex nomenclature. Illustrations of the principles of irreversibility can be found in many simple processes. Yet fallacies are often encountered in scientific papers published in reputable journals, showing that these principles are imperfectly understood, even by some who aim at instructing others.

The next speaker, Prof. F. E. Simon, advocated that the first introduction to thermodynamics should be at school ; only so would the second law be quickly mastered. Moreover, this should be done even if it necessitates sacrificing some of the more tedious parts of physics. He lamented the present inadequacy of elementary thermodynamic text-books, and while commending Ewing's book, he considers the engineer's approach far too restricted. In teaching thermodynamics he considers the use of complicated systems and involved mathematical derivations inadvisable. The main difficulty experienced by students is in grasping the fundamental ideas implied by the thermodynamic laws, and the best way of elucidating them is by the use of numerous examples. In this connexion he considers the heat pump as one of the best illustrations for bringing home to students the significance of the second law.

Speaking as a physical chemist, Mr. C. R. Bury claimed that the modern precise thermodynamics is of little use in meeting practical problems. The work of Van t' Hoff gave us a method that is easy to apply, but the answer is unreliable. The modern thermodynamics is only useful with very simple systems, and as soon as a problem occurs requiring high pressures, mixtures, or solutions, the information is so scanty that the methods are useless.

Dr. K. Mendelssohn emphasized that in teaching thermodynamics the primary need is to explain what the subject is about and not to plunge into a mass of symbols. A study of the phenomena occurring at the transition from the superconductive to the non-superconductive state affords useful instruction.

Dr. M. Ruhemann disagreed with Sir Charles Darwin that Newton's laws are more readily understood than the laws of thermodynamics. He personally has found Newton's second law more difficult to understand than the second law of thermodynamics. He agreed with other speakers that thermodynamics should be introduced at school, and he considers that by embodying it in examples such as internal combustion engines and fuels it could be made interesting to these ages. He commended warmly the text-book by Boznjaković and expressed regret that it is not available in English.

Dr. N. Kurti directed attention to the fact that in many universities there are several parallel and simultaneous courses in thermodynamics for chemists, physicists and engineers. If, instead, a combined course of lectures was given with emphasis on the nature and scope of the subject, considerable benefit would result. Mr. J. H. Awbery added to Dr. Ruhemann's contention, that the laws of thermodynamics are no more difficult than those of Newton, the point that students at school are drilled in mechanics at an age before they can ask questions, and it is solely this discipline which makes mechanics seem far easier. If thermodynamics was hammered home at an early age with plenty of illustrations, the concept of free energy would be as easy to understand as volume or temperature. Dr. L. R. G. Treloar also agreed with this point, stating that thermodynamics should be taught as dogma. Only so will familiarity and confidence be attained.

Summarizing the discussion, Sir Alfred Egerton indicated several points on which agreement had been reached. First, elementary instruction in thermodynamics should be given at school, and for this a very carefully prepared syllabus would be required. Secondly, in teaching thermodynamics more use should be made of diagrams and solid models; and thirdly, a unified system of notation is desirable. In conclusion, he pointed out that in 1850 Clausius and Kelvin had simultaneously, though independently, formulated the Second Law of Thermodynamics, and he expressed the hope that in 1950 the centenary would be suitably celebrated.

G. G. Haselden

NATURAL SCIENCE AND THE FINE ARTS*

By F. IAN G. RAWLINS

Scientific Adviser, National Gallery

I PROPOSE to consider here the relations which we may expect to find existing between these two great examples of human endeavour. In so doing it will be seen that the man of science, using that term in the broad sense, has been instrumental both in the fashioning of objects of art and in caring for them afterwards. It appears likely that many of the great masters of classical art were somewhat casual in their concern, as judged by our standards, for the beautiful things which they made; nowadays conservation has become an art in itself, and the philosophers are not slow in pointing out that our preoccupation with the treasures of the past may be bound up with a certain lack of confidence in ourselves to generate loveliness in our own time. However that may be, there is much to be said for a close study of the techniques of the great masters, and such a discipline does, in fact, help us to devise ways and means of looking after our heritage more adequately.

Thus, the man of science needs to be something of a *Kunstforscher* as well as competent to apply any method or methods which will help forward objective investigations of structure and condition. Clearly, one should know a good deal about materials and their limitations, above all to be imbued through and through with a sense of 'safety first', if museums and galleries are to reap positive advantages from the possession of a laboratory and its equipment. The war years, too, have provided problems on a scale commonly associated with those in engineering.

The greater part of this discourse will be devoted to the physics of classical paintings, chiefly because I find myself rather less incompetent perhaps with them than with other material; and secondly on the score of their combined weight and fragility, which makes them probably the most intractable of all. From the technical point of view they fascinate, not merely artistically, but because they are frequently so 'awkward'. At the National Gallery, for example, we have pictures weighing anything from a few ounces to nearly three quarters of a ton. To design plant both convenient and safe for such a range is not too easy. In surface area as well there is wide variation, from about 20 square inches to 16,000 square inches. The apparatus in question consists essentially of X-ray, ultra-violet and infra-red sources of radiation, with appropriate recording gear, both photographic and visual. In addition, there is considerable scope for colorimetry and for microscopy in polarized light. Further, the orthodox methods of photography have been extended to include macrographs, the use of special filtration processes, and the employment of raking light. In all this, one is not looking for the production of something that looks like the picture; we are seeking information which, in general, can only be obtained in bits and pieces, here a little and there a little, by deliberate exaggeration or suppression as the case may be. It is only when a purposeful effort at integration is made that the significance of these separate approaches becomes apparent. No method is known which by itself will tell us all that we wish to know, and unfortunately there are many examples in which failure occurs in spite of everything.

Here perhaps is the place to emphasize that scientific practice and methodology will never be substitutes for stylistic knowledge and insight. A certain amount of harm has occasionally been done to the cause of laboratory co-operation by expecting it to achieve results of which it is *a priori* incapable. Nevertheless, its help in confirmation, and briefly, in lifting conclusions out of the region of subjective judgment, has been demonstrated time and again. This only amounts to asserting the obvious truth that the nature of evidence needs extremely careful thought when using such evidence under conditions wherein the original assumptions cannot well possess full formal validity. Maybe this is why, in matters of this kind, there has been much reasoning by analogy, that is, from particular to particular. Scientific method will strive to raise this one degree in the hierarchy by attempting to apply the process of induction (that is, reasoning from the particular to the general); so far as one can see, it seems most unlikely that the final, or deductive, system will ever be reached in scholarship of the type we are contemplating now, since argument from the general to the particular is almost a denial of the individualism of art. It is a fact, however, that a remarkable degree of agreement is often registered among people thoroughly conversant with questions of style, iconography and provenance, but this is not to say that objective testing has no place in these deliberations. Its verdict *may* be crucial.

My purpose thus far in sketching, necessarily briefly, the theoretical background of the scientific-artistic complex has been to try to elucidate certain basic suppositions which experience shows to be liable to misapprehension or even to neglect. It is easy to claim too much; equally faint-hearted is it not to realize the force of analytic and synthetic means as signposts on the journey. With these dispositions in mind, we can tackle the experimental problems which await us with greater confidence. To some extent, our advances must be by comparative methods, that is by the use of models, since obviously no risks can be run with irreplaceable originals.

---

* Substance of a Friday evening discourse delivered at the Royal Institution on February 14.

We now discuss in some detail the physical structure of a typical painting in oil or in tempera. Its most marked characteristic is its stratified nature; that is, it is built up of a number of layers. These are, starting from the back: (1) the support; (2) the ground; (3) the paint film; (4) the surface film. The physical boundary lies between (1) and {(2), (3), (4)}, since the support is essentially—for our present purpose—composed of a biological fibre (wood or canvas, or both), whereas the three superincumbent members are film-substances, differing mainly in the amount of pigment and medium which they contain. They are traditionally enumerated separately more on account of their method of application and purpose than for their differing chemical natures.

At the moment, however, I propose to consider particularly (3), for the paint film *is* the picture as commonly conceived. It is the design itself, and upon it, essentially, the æsthetic value of the whole depends. In many cases the paint film is itself complex, consisting of a number of components. These often show a lack of continuity in one plane, a rough parallel with the 'faults' of the geologist. Again, imbrication is not uncommon, which adds many a trap for him who has forgotten to walk like Agag. In general, interpretation of structure is difficult, by whatever means it is attempted.

Within the paint film itself (that is, restricting ourselves to one plane), we are confronted with a sequence or gradation of properties depending in the main upon the relative properties of pigment and medium. Paint structures rich in pigment are called *granular* (examples are to be found in most fresco and wall paintings); those of medium concentration are known as *vehicular* (a large class containing most normal easel paintings); and finally, phases very rich in medium are termed *pellicular*. In this latter group are found the glazes and, in the limit, pure oil films. The important point to notice about this scheme, which is due largely to G. L. Stout of Harvard University, is that whereas chemically all these entities are simply so much paint, the ordinary appearance depends mostly upon the state of aggregation, while the physical properties such as transmission, reflectivity, permeability and so on show correspondingly transitional characters.

From the point of view of the impact of electromagnetic radiations, however, we are concerned more particularly with the chemical nature of the pigment particles themselves. Thus, as is well known, lead in any of its numerous compounds is very opaque to X-rays, and so, of course, are the other heavy elements. It is for this reason that our X-radiographs of a picture represent a kind of scaffolding of the 'edifice', delineated into areas of high lead content. Ultra-violet tests, on the other hand, function because of the capacity of certain pigments to excite fluorescence, an effect which is not independent of the medium, whereas discoloured varnish is often reasonably transparent to the near infra-red. Naturally, a complete examination will include all these methods, and, as indicated earlier, no one of them alone is likely to tell the whole story. In general, each has its particular part to play.

At the risk of falling into the sin of over-simplification, I should mention that there are two ways in which an artist may build up his structure. One is to allow the ground, that is, No. 2 of the strata already mentioned, to provide the body of the lighter parts of the composition, adding white lead, perhaps very thin, for the high lights. Franciabigio's Portrait is an example. Alternatively, the whole of the lighter areas, including the high lights, can be painted in lead, beginning, of course, with a dark, or darkish, background. A head by van Dyck shows this technique well. Actually it is unlikely that a specimen can be produced to give a complete case of either practice; most instances are mixtures of both, inclining perhaps more one way than the other. But the conception is a useful one for technical purposes, and X-rays are capable, in general, of exhibiting these distinctions satisfactorily. All the layers, unfortunately, except those which are exceedingly thin, are registered together, which makes interpretation all the more difficult and at times uncertain. By reducing the penetrating power of the rays, gradation is much improved. We use 14 kV. or 21 kV., with a current of 15 ma. at the National Gallery, and are planning to go to still lower potentials. Exposure times are from two to three minutes, depending, of course, upon the thickness and nature of the support, as well as upon the type of ground and paint film. Good results may be expected if the ground is of *Gesso* (plaster of Paris), but not if a lead priming is present, or if a lead-bearing adhesive has been used in the course of relining. Radiography is defeated in these cases.

The ultra-violet is occasionally a very powerful weapon in a museum laboratory. So far as paintings are concerned, it is possible to reveal retouchings and to observe to what extent the surface film is intact. A characteristic fluorescence is excited. It follows that if it is desired to study the paint film in this way, it is essential to remove the varnish, the fluorescence from which is usually intense enough to obliterate everything else. In general, the ultra-violet is a means of dealing with surface phenomena, the penetration being nearly zero. At the other end of the wave-length scale we have infra-red radiation. Certain practical difficulties are commonly encountered, but the method has great possibilities, greater perhaps than those of X-rays. The reason for this is that, with orthodox X-ray equipment, as already mentioned, superposition effects cannot be avoided, whereas, naturally, they do not occur with a reflexion phenomenon such as infra-red photography. Thus varnish, even when highly discoloured, is usually penetrable; and if this is the case, a much improved image of the paint film is obtained compared with an ordinary photograph. At their best, infra-red records can be very significant, particularly for such masters as Tura, Crivelli, and Cossa, where exceptional under-modelling is brought out, and their anatomical build-up displayed. From ordinary vision, most of this is hidden.

It has probably become clear that much of what I have been saying so far is applicable *mutatis mutandis* to a variety of museum material other than paintings. Instrumentation will be a little different, and probably there will be greater scope for chemical investigations. The ultra-violet has not infrequently proved effective in the detailed study of pottery, and, as is well known, for the elucidation of manuscripts and drawings. An ingenious application of electro-endosmose has been for the cleaning of pottery, of which the surface has become encrusted with salt crystals in which some pigment is entangled. The homely method of a good scrub with water would quickly end in disaster, since the precious coloured particles would be scattered far and wide by such treatment. But by immersing the vase in water, and inserting a cathode wire into it as one electrode, and using another wire dipping into the water as the anode, the salt crystals conveniently move off in one direction, whereas the pigment grains are drawn back on to the surface of the vase, to which they can then be anchored by the application of shellac; 30 volts D.C. for about half an hour is enough.

Another striking example of laboratory technique has been the mounting of Foraminifera from the limestone supports of classical fresco murals by means of thermo-plastic resins. Micro-sections can be made in this way from such friable material and preserved for archæological research in a convenient and permanent form.

At the beginning I referred briefly to the task of conservation in general. This is a matter which concerns the man of science very closely; and given the requisite knowledge for, and appreciation of, the task, he should be able to render valuable assistance. The experience gained during the War has been, or is being, turned to good account, and will assuredly influence future practice in gallery construction. With regard to the all-important subject of air-conditioning, it is essential to realize that any scheme must provide not only an appropriate environment for the exhibits, but also for the public. Repository surroundings during the war years can scarcely be considered as sure guides, since their only purpose was to take care of the valuables: the comfort and convenience of visitors did not arise. In short, we are now faced with a much more complex problem. Luckily, as regards relative humidity—the most vital single factor from the technical point of view—the human body is remarkably accommodating, much more so than with respect to temperature. Therefore we can provide a range of moisture-content well suited to the particular material, without the introduction of disagreeable features on that account. More trouble is likely to be met with in Britain in dealing with buildings architecturally unsuitable (as many are), and on account of our erratic climate.

In very general terms, the aim should be to prevent, or at least to diminish, the 'working' of substances like wood, textiles and so forth; or in the language of physics, to restrict the area of the hysteresis loop for wetting and drying to a minimum. This means keeping the moisture-content nearly level, which in its turn indicates the need for a constant relative humidity—say around 60 per cent for most exhibits.

More attention than hitherto will need to be paid to the so-called 'near-surface' effects. In other words, the relative humidity in the centre of a large room is not the same, even in the absence of temperature gradients, as that near the surface of objects placed in it. The reasons for this are complicated, but they point to the necessity of micro-determinations if trustworthy data are to be obtained for precious things, even if they are immersed in a nearly infinite reservoir of air of statistically satisfactory thermodynamic properties.

Given a return to something remotely approaching normality, there are good opportunities in the museum world: openings are not numerous, but they offer interesting careers with plenty of responsibility and scope for originality. But all on one condition. Natural science in such a context is ancillary to the fine arts in the literal sense of the word. She is art's serving maid; yet art must be sympathetic, apt to realize not only what science can do, but also what an objective philosophy can teach. Then all will be well. Such is our intention; and striving to attain it, not weighing our merits, but pardoning our offences, is, I take it, no more than our bounden duty and service.

OBITUARY

Dr. H. M. Tory

HENRY MARSHALL TORY died in Ottawa, Canada, on February 8, at the age of eighty-three. At the time of his last illness he was president of Carleton College, a post which he had filled from 1942 when he was instrumental in founding this institution of higher learning. At that time he had returned to active academic work after having enjoyed a few years of well-earned rest following a long life of high achievements. Thus once again his great talents for organisation were directed towards the establishment of yet another college. Early in his career he had contributed in no small measure to the founding of the University of British Columbia at Vancouver, and later the University of Alberta at Edmonton. He had directed the organisation of "Khaki College" in the First World War, and had been the first full-time president of the National Research Council of Canada. By virtue of his many high offices and as he was by natural bent a philosopher and an earnest educationist, he was widely recognized as one of Canada's most distinguished sons.

Born in Guysboro, Nova Scotia, on January 11, 1864, Tory was educated in the local academy and at McGill University, Montreal, where he graduated, a gold medallist in mathematics and physics, in 1890, and then continued on the staff as lecturer and associate professor, teaching mathematics and physics, and gaining a master's degree in 1896, and a doctorate in science, 1903.

From 1908 until 1928 he was president of the University of Alberta. His successors in office at that western institution have paid moving tributes to Dr. Tory's memory. Dr. R. C. Wallace, who succeeded him and is now principal of Queen's University, said: "He was a stalwart in the cause of world peace and intellectual co-operation, an able exponent of science in the modern world, and a warm friend to distressed peoples everywhere. There are not many men of Dr. Tory's stature in a generation, for he built the things that will endure"; and Dr. Robert Newton, president of the University of Alberta, expressed the feelings of many when he observed: "Dr. Tory was the greatest Canadian figure of his time in the field of education and scientific research".

Always actively interested in all matters concerning the welfare and progress of the Dominion and its people, Dr. Tory found himself chosen time and again to serve on royal commissions and boards established by various authorities to inquire into such diverse subjects as agricultural credits in Europe (1913) and in Canada (1923–24); coal classification (1923–35); the fruit industry in Nova Scotia (1930); and the coal industry (1936). He was a special commissioner from Canada to the Pan-Pacific Science Congress in Japan, 1926, and it was largely through his efforts that Government authorization was secured for the holding of the Fifth Pacific Science Congress in Canada in 1933. He organised the Congress and served as its president (1930–34). He served as colonel-director of educational services for the Canadian Overseas Forces during 1917–19.

His outstanding qualities as an educationist and leader in science and culture were recognized repeatedly by the award of honorary degrees and other distinctions. He received the honorary doctorate in laws from St. Francis Xavier College in 1906; from McGill in 1908; University of Toronto, 1927; Saskatchewan, 1928; Alberta, 1928; McMaster, 1932; British Columbia, 1932; Western Ontario, 1933; and a doctorate in civil law from Acadia, 1935. He was Governors' fellow of McGill University during 1905–8 and non-resident fellow 1908–15.

A fellow of the Royal Society of Canada, Dr. Tory held office as chairman of the physico-chemical section in 1927 and as president of the Society in 1940. He was a fellow of the Royal Historical Society and had a deep and abiding interest in history, in which subject he lectured at the University of Alberta. He was more especially interested in the history of philosophy and science, and conducted classes in these subjects at Carleton College. The Tory collection in the National Research Library was founded by his friends to commemorate his interest in this field of study.

In February 1923, Dr. Tory was appointed a member of the honorary advisory Committee for Scientific and Industrial Research, and named as chairman in October of the same year. He became director of the laboratories at Ottawa when these were still housed in temporary quarters, and president of the Council in 1927. Under his presidency, construction of the National Research Building was undertaken in 1930. He personally directed the planning of this fine structure, which was opened by Mr. Stanley (now Lord) Baldwin, at the time of the Imperial Economic Conference in Canada, 1932. Before he retired from the presidency of the Council in 1935, he had selected the original staffs for the laboratories and established the standards of ability and performance which enabled the institution to meet the challenge of war as it did.

Those with an intimate knowledge of Dr. Tory's work as president of the National Research Council will feel that his contributions to organised scientific and industrial research in Canada, which are acknowledged to-day, will loom larger still as the years lend perspective to the progress which Canada is making in this field. "An example and an inspiration, this man of the deepest integrity and the fullest public spirit will not soon be forgotten by the generation he served so admirably and so efficiently."

C. J. Mackenzie

NEWS and VIEWS

Royal Society: New Foreign Members

The following have been elected foreign members of the Royal Society:

Dr. E. J. Cartan, professor of geometry in the University of Paris and member of the Paris Academy of Sciences, distinguished for his fundamental work in the theory of continuous groups and in differential geometry;

Prof. P. Karrer, professor of chemistry in the University of Zurich, distinguished for his outstanding contributions to the chemistry of natural products, with special reference to the chemistry of the carotenoids, carbohydrates and vitamins;

Prof. H. C. Urey, professor of chemistry and director of the Institute for Nuclear Studies, University of Chicago, distinguished for his discovery of deuterium, for his investigations into the separation and properties of isotopes, and for the application of these discoveries in the development of methods for producing atomic energy;

Dr. Øjvind Winge, of the Carlsberg Laboratory, Copenhagen, distinguished for his many fundamental contributions to the cytogenetics of plants and animals.

Royal Naval Scientific Service: Sir Charles Wright, K.C.B., O.B.E.

Charles Seymour Wright, who has just resigned from the post of chief of the Royal Naval Scientific Service, was born in Toronto in 1887. He was educated at Upper Canada College and the University of Toronto. He won a Wollaston Research Studentship and an 1851 Exhibition Scholarship, with which he proceeded to Gonville and Caius College, Cambridge. He did research work at the Cavendish Laboratory during 1908–10. He joined Captain Scott as scientist to the Antarctic Expedition, 1910–13. After the return of the survivors of this expedition, he spent a year at Cambridge until the outbreak of war. He joined the Royal Engineers in 1914, first as wireless officer to the 5th Corps, during which period he earned the Military Cross. He later became O.C. Wireless of the 2nd Army, and for his services at this time was made a Chevalier of the Legion of Honour. He was decorated with the O.B.E. for his subsequent work in the Intelligence Division of the General Staff.

After he had been demobilized, he became senior assistant to Mr. F. E. (later Sir Frank) Smith, then director of the newly formed Department of Scientific Research and Experiment at the Admiralty. In the same service he was appointed superintendent of the Admiralty Research Laboratory, Teddington, in 1929, a post which he held for five years. He became director of scientific research at the Admiralty in 1934 and carried throughout the Second World War the high responsibilities of this director's position as well as during the rearmament period preceding it. With the formation of the Royal Naval Scientific Service in 1946 and the reorganisation of Admiralty arrangements for the direction of scientific research, he was appointed first chief of the Service. He was made a C.B. in 1937 and a K.C.B. in 1946. All who served under him received help and guidance from a most genial personality. He will be greatly missed by his colleagues and by the scientific workers with whom he came in contact elsewhere.

Mr. F. Brundrett, C.B.

The Admiralty has announced that Mr. F. Brundrett has been appointed chief of the Royal Naval Scientific Service in succession to Sir Charles

Wright. Mr. Brundrett went to Sidney Sussex College, Cambridge, and obtained first-class honours (Wrangler) in the Mathematical Tripos. During 1916–19 he served in the R.N.V.R., and then was appointed to the scientific staff of H.M. Signal School, where he served in various capacities until 1937, his most outstanding original technical work being on the propagation of short wireless waves and in the organisation of world-wide propagation trials. In 1937 he was transferred to the Scientific Research and Experiment Department, Admiralty, as principal scientific officer, where a sequence of rapid promotions led to his becoming a deputy director of scientific research in 1942. In 1946 Mr. Brundrett was appointed assistant to the chief of the Royal Naval Scientific Service for the reconstruction period.

At the start of the Second World War, as many hundreds of scientific men throughout Great Britain will know from personal experience, Mr. Brundrett accomplished with great success a prodigious task in organising and recruiting a vast expansion of the Navy's scientific staff, and in the radar research branches of the other Services. He was throughout the War particularly prominent in the organisation and administration of radio valve research for the Services. He was honoured with the award of the C.B., in recognition of his war-time work, in the New Year Honours, 1946. Mr. Brundrett has a farm in Hampshire where he has achieved great success in the breeding of pedigree poultry and Red Poll cattle.

Physics at King's College, London: Prof. C. A. Coulson

Dr. C. A. Coulson, recently appointed to the University chair of theoretical physics at King's College, London, is among the foremost workers in Great Britain on the wave-mechanical side of quantum theory. Although Coulson's research papers cover a very wide range of interests (he collaborated with Lea and Haines in early work on the action of radiation on bacteria and has also made contributions to the theory of liquids and solutions), the great bulk of his published work deals with the application of wave-mechanics to the theory of molecular structure. It has been concerned both with the determination of accurate wave-functions for simple molecules and molecular ions and with the necessarily more approximate treatment of large organic molecules. An extensive series of papers in collaboration with W. E. Duncanson deals with the rather neglected field of momentum distribution functions and the related Compton-line profiles.

In the theoretical treatment of large unsaturated molecules, Coulson uses the method of molecular-orbitals originally due to Hückel and first developed in Britain by Prof. (now Sir John) Lennard-Jones at Cambridge. Coulson has used this method for a great variety of problems, from the computation of the bond-lengths of such a molecule as coronene to a calculation of the electrical conductivity of pure graphite. Recently, at Oxford, Coulson and his co-workers have made considerable advances towards an understanding of the effects of substituents in molecules and a general theory of chemical reactivity. In addition to his research papers, Dr. Coulson has also written text-books on the more elementary and classical aspects of mathematical physics. He has a well-deserved reputation for his kindly and helpful encouragement of younger research workers.

Food and Agriculture Organisation: Production and Research

Dr. G. Scott Robertson, Permanent Secretary of the Ministry of Agriculture for Northern Ireland, has been seconded for a period of six months to take up the post of director of agricultural production and research under the Food and Agriculture Organisation of the United Nations. Dr. Scott Robertson went to Northern Ireland in 1922 and held the dual post of professor of agricultural chemistry in the Queen's University of Belfast and senior research officer of the Ministry of Agriculture. It was during this period that he continued the now classic work on phosphatic fertilizers which he had been conducting for several years in Essex while head of the Agricultural Chemistry Department of the East Anglian Institute of Agriculture. At the same time Dr. Scott Robertson started a series of investigations on the mineral requirements of farm livestock, paying particular attention to those of poultry. This work was carried out in close collaboration with Sir John Boyd Orr, who was then director of the Rowett Research Institute. In 1928, Dr. Scott Robertson became chief inspector of the Ministry of Agriculture for Northern Ireland, and later was appointed permanent secretary when Dr. J. S. Gordon retired. For many years Dr. Robertson has acted as assessor on the Agricultural Research Council and United Kingdom delegate to the meetings of the Imperial Agricultural Bureaux. Thus he brings to his new work many years experience in agricultural research, coupled with administrative knowledge gained as head of a department the energies of which have been devoted to the task of production at the highest possible level for more than seven years.

Research in the Region between Subsonic and Supersonic Speeds

There is a large gap in our knowledge which must be bridged before we can take decisive steps from present aircraft subsonic speeds to supersonic speeds. There is first of all the question as to what happens when actually passing through the range of speed about that of sound. It is known that we must expect a steep rise of drag in this region, but we have no quantitative information. There is the further question of change of trim and stability in level flight as one passes from subsonic to supersonic speeds. There are other questions of aerodynamic and structural significance, and the whole problem is rather complex. Normally one would expect to get a large part of this information from wind tunnels, and although the capabilities of existing wind tunnels will be used to the limit, nobody knows how to design or use a practicable wind tunnel at or about the speed of sound. The phenomenon known as 'choking' and the effect of wall interference prohibit the use of tunnels for model tests at Mach numbers between about 0·9 and 1·15. This is the main reason for going into the air, and a series of experiments has been planned to use flying model aircraft launched from a great height from another aircraft and powered by rockets. This form of propulsion should enable the models to be driven through the speed-range of that of sound to various supersonic speeds.

The models will be fitted with instruments, and a six-channel telemetering system will transmit readings continuously to the ground, giving information on speed, height, Mach number, drag, lift coefficient and longitudinal trim. Radar observations will also be made on the flight path. All this involves a new research technique, and early experiments will be mainly concerned with perfecting it. Step by step it is hoped to reach the position where enough information will be available to design a supersonic radio-controlled aircraft. The rocket thrust is about 850 lb. acting for some 70 sec. An auto-pilot controls the model in pitch and roll. It is proposed to release the model at 36,000 ft. from a Mosquito aircraft, when the controls will operate to cause it to glide down to 35,000 ft. The rocket motor will then be switched on to accelerate the model in roughly level flight, at this height, to an estimated Mach number of about 1·3. When the fuel is all burnt the model will decelerate, its speed passing through that of sound to subsonic velocity; so a double chance will occur of getting readings in the critical transonic region before the automatic controls operate to crash the model into the sea. The models have been designed by Mr. B. N. Wallis, of Vickers-Armstrong, and made there in collaboration with the Royal Aircraft Establishment, which is responsible for the conduct of these experiments. The experiments should start in about a month's time off the Scilly Isles.

Chemistry at the University of Sheffield

The Staveley Coal and Iron Co., Ltd., near Chesterfield, has decided to make a gift of £50,000 to the University of Sheffield in order to promote the furtherance of research within the University and especially in the Department of Chemistry. The Company, which is concerned with the production of iron, caustic soda, chlorine, hydrochloric acid, chlorates, aniline and a wide range of basic coal-tar products, takes the view that encouragement of free chemical research in universities must, in the long run, benefit both the Company and industry as a whole, and believes that the connecting of industrial development with academic discovery is essential for national prosperity. Its gift to Sheffield is most opportune, as the provision of a new Department of Chemistry is one of the most urgent parts of the post-war plans of the University's extension scheme. It is intended to replace the existing laboratories, built in 1905, by an entirely new department which will be close to the present building of the University in Western Bank. The new building has been designed to provide adequate space for all the work in the Department when the University attains its projected number of 3,000 full-time students in all faculties, and adequate research facilities will be provided for investigations in analytical, inorganic, physical and organic chemistry. It is estimated that the cost of the erection of the new Department will exceed £400,000, and it is proposed that the research laboratories therein should be named the "Staveley Laboratories".

A New Rat Poison

To the well-known list of rat poisons, such as arsenic trioxide, red squill and zinc phosphide, the last years of the War added another, α-naphthathiourea. Dr. C. P. Richter, of Baltimore, was responsible for showing that its toxicity to *Rattus norvegicus* was high (A.L.D./50, 10 mgm. per kilo body-weight). Somewhat extravagant claims were made for its effectiveness when applied as a direct bait. In none of the field tests were accurate censuses made of the rat population before treatment. Prolonged and detailed experience in Great Britain at the Bureau of Animal Population has shown that knowledge obtained by bait census is essential before field trials are undertaken. The use of α-naphthathiourea as a dusting powder, however, opened up possibilities of a new method of application, but its usefulness depended upon the safety factor involved. Toxicity tests made on other animals showed an enormous range of sensitivity. *R. rattus*, the ship or black rat, had an A.L.D./50 of 250+ mgm. per kilo body-weight, more than twenty-five times that for *R. norvegicus*, while *Mus musculus*, the house mouse, had an A.L.D./50 of 80–90 mgm. per kilo body-weight. These data showed that it was impossible to predict a safety-level from one species to another. Consequently, although tests on monkeys (*Macacus* sp.) showed a high resistance, it was dangerous to assume that man was equally immune. Dusting application was therefore not advised in Great Britain until more information was available.

Used in baits, following the pre-baiting technique worked out by the Bureau of Animal Population, α-naphthathiourea gave results as good as those with arsenic and zinc phosphide, namely, 90 per cent kills; used as a direct bait without prebaiting, some successes were met with, but also the usual failures (for example, 40 per cent kill). Since the failure to exterminate rats is largely due to the hit and miss nature of direct baiting which has been employed for so long, there seemed no grounds for regarding α-naphthathiourea as any considerable advance on the well-established poisons. α-Naphthathiourea is now being marketed by the Rodmill Chemical Co., Ltd., as 'Antu', containing 2 per cent of the active principle. As a ready-to-use compound bait, 'Antu' must be classed with the direct baits which do not allow the purchasing public to pre-bait and ensure success. It is also being recommended as a dusting powder for use in rat runs, on beams and elsewhere "inaccessible to domestic animals"—places which may be hard to find. From the point of view of rodent control, it is to be regretted that α-naphthathiourea is not being marketed at a 20 per cent concentration in an inert medium and so allowing the public to obey the recommendations of the Infestation Division of the Ministry of Food to pre-bait before poisoning, a technique worked out by the Bureau of Animal Population during the War, which has proved itself again and again to be the only really certain way of exterminating rats.

Exhibition of Applied Photography

An Exhibition of Applied Photography arranged by Kodak Ltd. at Australia House, Strand, London, was opened on May 6 by Prof. E. N. da C. Andrade. The exhibits illustrate a very wide range of industrial and commercial applications of photography, the applications being illustrated by photographs, diagrams and in some cases demonstrations. Photography received a fair amount of publicity during the War, particularly on account of its obvious importance for air reconnaissance. There were, however, many other applications less spectacular, but nevertheless of great value, many of which are illustrated in some form in this exhibition. Most of these applications have come to stay and will play a useful part in peace-time industry. The range covered by the exhibition is very wide; on the spectacular side is a full-sized radiograph of a 'Jeep' to set against the purely utilitarian micro-copying of documents. Other exhibits include industrial radiography, gamma radiography, stereoscopy, photography in education, colour reproduction and the reproduction of drawings on metal. Among the most interesting exhibits are the 16-mm. projectors showing continuously running films of mechanical and manual operations, some in slow motion, to illustrate how an analysis of the motion can be used to speed up, or reduce fatigue in, the operation. Most of the exhibits illustrate industrial applications of photography, and the whole provides an interesting collection well worth a visit. The exhibition remains open until May 16.

Congresses

Radiation Chemistry and Photochemistry

A SYMPOSIUM on radiation chemistry and photochemistry is being arranged at the University of Notre Dame during June 24–27. Particulars can be obtained from Prof. Milton Burton, Department of Chemistry, University of Notre Dame, Notre Dame, Indiana.

Spectroscopy

THE Groupement pour l'Avancement des Méthodes Spectrographiques is organising a general meeting to be held during June 23–25 at the Laboratoire Central de l'Armement, 1 place Saint-Thomas d'Aquin. Two sessions will be devoted to emission spectroscopy and the third more particularly to colorimetric methods of analysis. Particulars can be obtained from the offices of the Group at the place of meeting.

Aeronautics

AN Aeronautical Congress will be held in London during September 3–6, at which papers will be read, followed by discussions, on the technical aspects of aviation. The Congress is being arranged by the Royal Aeronautical Society in close co-operation with the Institute of the Aeronautical Sciences of America, and about half the papers will be by American authors. A tentative programme of some twenty papers has been arranged under the following sections: aerodynamics, structures, power plants, stability and control, air-worthiness and safety, high-altitude flight, telemetering, helicopters and light (personal) aircraft. A detailed programme will be available shortly from the Royal Aeronautical Society.

Physical Chemistry

AN advanced course in physical chemistry for graduates in industry, colleges of technology and schools, will be held at the University of Leeds during August 25–September 5. The main topics will be the wave nature of matter in chemistry; molecular structure and chemical reactions; the arrangement and structure of molecules in the solid state. Particulars of the course and forms of application may be obtained from the Director of Extra-Mural Studies, The University, Leeds 2.

Cytology

THE sixth international Congress of Experimental Cytology will meet in Stockholm during July 10–17. The Congress will consist of a series of symposia on (*a*) chemical constituents of the cell; (*b*) submicroscopic structure of protoplasm (including viruses); (*c*) nuclear and cytoplasmic interactions; (*d*) cell metabolism; (*e*) development, growth and differentiation. General surveys will be given, followed by discussions and short papers relating to the above subjects. The organising committee is prepared to arrange accommodation. Particulars relating to the Congress can be obtained from the secretaries, Prof. T. Caspersson and H. Hydén, Karolinska Institutet, Institute for Cell Research, Stockholm.

Announcements

A MEETING in memory of Paul Langevin has been arranged by the Society for Visiting Scientists, the Association of Scientific Workers and the World Federation of Scientific Workers, to be held on May 25 at 7.45 p.m. at the Beaver Hall, Garlick Hill, London, E.C.4. Sir Henry Tizard will take the chair, and the speakers will include M. Pierre Biquard, of the French Commissariat of Atomic Energy and the Paris School of Physics and Chemistry, Sir Harold Spencer Jones, Sir George Thomson and Prof. J. D. Bernal.

DR. LAWRENCE L. LACHAT, senior fellow at the Mellon Institute, Pittsburgh, Pa., has resigned to accept a new position with the Chemical Research and Development Department, Armour and Co., Chicago, Ill., where he will be in charge of the development of new biochemicals which largely became available as a result of war-time research between Armour and Co. and the U.S. Office of Scientific Research and Development.

RECENT publications of the Federal Security Agency, U.S. Office of Education (Washington: Gov. Printing Office), are of interest as showing the heed paid by the United States as to the state of education in South America. Three bulletins at hand deal with Costa Rica, Colombia and Peru, and all of them merit attention by students of comparative education.

A FULL report of the two-day conference on "Industry and Research" arranged by the Federation of British Industries in March, 1946 (see *Nature*, **157**, 684; 1946), has now been published by Sir Isaac Pitman and Sons, Ltd. (London, 1946. 10*s*. 6*d*. net). It includes a preface by Sir Clive Baillieu, and, in addition to the papers presented, the addresses of the various chairmen and reports of the discussions at the sessions on scientific research and production, scientific research and industrial expansion and the application of research in industry.

WITH the financial help of private individuals and of the Juan Bautista Sauberan Foundation of Buenos Aires, an institute for research in fundamental branches of medicine has been organised in Córdoba, Argentina (25 de Mayo 1122); it will be known as the Instituto de Investigación Médica para Promoción de la Medicina Científica. The staff includes, among others, Dr. Oscar Orias (director), Dr. Enrique Moisset de Espanés and Dr. Inés L. C. de Allende. All three formerly held travelling fellowships of the Rockefeller Foundation; Dr. Orias working at Western Reserve and Harvard Universities with Profs. Carl J. Wiggers and the late Walter B. Cannon; Dr. Moisset de Espanés at Harvard University with Prof. Otto Krayer, and Dr. de Allende in Rochester, N.Y., and New York, with Profs. George W. Corner and Efrain Shorr. They held posts in the Institute of Physiology in the Medical School of the University of Córdoba, but resigned after the recent changes in the administration of the universities of Argentina. The new Institute is a private institution; its main activity will be research in endocrinology, pharmacology and physiology of the circulation of the blood.

ERRATUM. In the penultimate paragraph of "Synthesis of Methionine and Similar Amino-Acids" by J. R. Catch *et al.* (*Nature*, April 26, p. 578), for "α-amino-γ-thio-1-γ-methyl-*n*-valeric" read "α-amino-γ-thiol-γ-methyl-*n*-valeric".

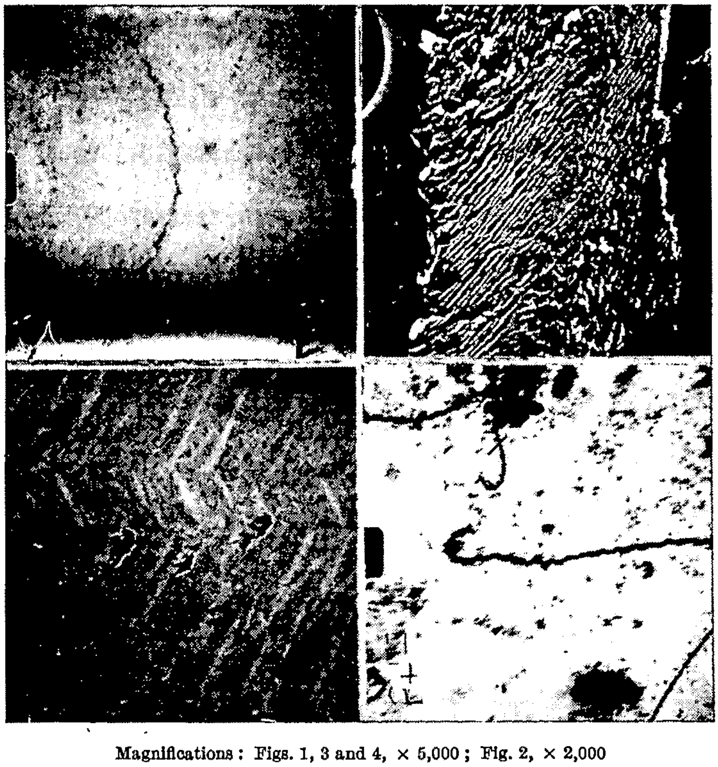
A Methyl Methacrylate–Silica Replica Technique for Electron Microscopy

Barnes, Burton and Scott[1] have described a modified polystyrene–silica replica technique for the study of organic surfaces; but owing to the high temperatures (130° C.) involved in the formation of the intermediate replica, their method is unsuitable for water-containing substances. They suggest, however, 'that some plastics such as isobutylmethacrylate are sufficiently thermoplastic at temperatures below 100° C. to give the necessary resolution without total drying of the specimen.

We have used a method of actual polymerization from the liquid monomer of methyl methacrylate poured over the surface of the specimen, and by it obtained electron-micrographs of silica replicas of metallic surfaces, blood cells, *Leptospira* and other materials. The intermediate replica may be formed at any convenient low temperature—even at room temperature or below—and no pressure is required, since the monomer is applied as a liquid, the viscosity of which is entirely under control. Thus it is only necessary to remove any surface water from the specimen to be examined.

In the case of metallic surfaces, the method has, in general, no advantage over the polystyrene-thermoplastic technique, but may be useful in the case of metals which oxidize very readily. Its importance is obvious in the examination of biological material.

Figs. 1, 2 and 3 are examples of the electron micrographs, methyl methacrylate being used for the intermediate replica in each case. Fig. 1 was obtained from *Leptospira canicola* dispersed on a glass slide, fixed in osmic acid vapour and superficially dried; Fig. 2 shows twinning and grain boundaries in thermally etched silver, and Fig. 3 shows fine structure in pearlite steel. For comparison with Fig. 1, Fig. 4 is an electron-micrograph of *Leptospira canicola* obtained with the organism mounted on a nitrocellulose film in the electron microscope. The close similarity between Figs. 1 and 4 suggests that *Leptospira* is not changed by the electron bombardment and drying which it undergoes in the electron microscope.



Magnifications: Figs. 1, 3 and 4, × 5,000; Fig. 2, × 2,000

To obtain the methyl methacrylate replica, methyl methacrylate monomer stabilized with 0·1 per cent hydroquinone is treated in the following way (the stabilized monomer may be obtained from I.C.I. Ltd. under the trade name of 'Kallodoc'). The method is very similar to that used by workers in other fields.

Step 1. The hydroquinone is removed in caustic soda by shaking 100 c.c. of the stabilized material with 20 c.c. of 20 per cent (w/v) aqueous caustic soda in a separating funnel and running off the brown bottom layer. The methyl methacrylate is washed with two lots of distilled water in a separating funnel, the bottom layer being run off in each case, and it is dried by standing for a night over about 5 gm. of anhydrous calcium chloride in a beaker. This destabilized liquid may be kept in a cool dark place for some months.

Step 2. About 5 c.c. of the destabilized methyl methacrylate is heated at 90° C. for about half an hour with 0·003 gm. of benzoyl peroxide. The time of heating may be varied to give a more or less viscous liquid. A lower viscosity will give a better resolution through being able to enter the small interstices of the surface, but will take considerably longer to polymerize on the specimen.

Step 3. (*a*) The treated methyl methacrylate from (2) is poured over the specimen and allowed to 'set' at 60° C. overnight; or (*b*) the treated methyl methacrylate from (2) is allowed to cool to room temperature (or below if required) and is then poured over the specimen and allowed to 'set' at this temperature.

The methyl methacrylate is now teased from the specimen with a razor blade and is coated with silica as described by Heidenreich and Peck[2] in the polystyrene–silica replica technique. The method of removing the silica is also analogous to that used in the polystyrene–silica method, the only difference being that the methacrylate is dissolved away in toluene and the silica films washed in clean toluene.

Methyl methacrylate has an advantage for this replica technique in that pieces of the body investigated, which might stick in the methacrylate, may be removed in dilute acids or dilute alkali without impairing the replica. *Leptospira*, for example, dissolves in 5 per cent (w/v) nitric acid.

A silica replica is also preferred to a 'Formvar' or collodion replica, this being also found by other workers[3].

Dr. J. A. H. Wylie of the Sir William Dunn School of Pathology, Oxford, prepared and dispersed the *Leptospira*, and Miss D. M. Williams assisted with all the electron-microscopy work. The work was started at the Clarendon Laboratory, Oxford, and continued at the Atomic Energy Research Establishment, and was done with an R.C.A. *EMC* console type electron microscope. It is published by permission of the Director, A.E.R.E.

Optimum Disturbing Field for Synchrotron Beam Ejection

Several methods have been suggested[1,2,3] for using disturbing magnetic fields to eject an electron beam from a synchrotron or betatron. Important differences exist in these methods in the angular distribution of these disturbing fields. Thus the 'orbit expansion' method[1,2] effectively applies a sudden decrease of field over the whole 360° of annulus, while the '+ − field' method[3] decreases the field over 180° of annulus, while increasing it over the other 180°. The considerations outlined in this communication lead to the suggestion of an 'optimum step field', that is, a disturbing field of angular length such that the required beam displacement is obtained with minimum reactive power in the ejector field coil.

Consider the motion of an electron of energy $E = 300\, H_0 r_0$ in the magnetic field:

$$\left.\begin{array}{l} H = (H_0 - \Delta H_0)\,(r/r_0)^{-n} \text{ for } -\theta_1/2 \leqslant \theta \leqslant \theta_1/2 \\ H = H_0\,(r/r_0)^{-n} \text{ elsewhere.} \end{array}\right\} \qquad (1)$$

The decrease in field, ΔH_0, causes an increase in equilibrium orbit radius of Δr_0, where, letting $K = \sqrt{1-n}$,

$$K^2\, \Delta r_0/r_0 = \Delta H_0/H_0. \qquad (2)$$

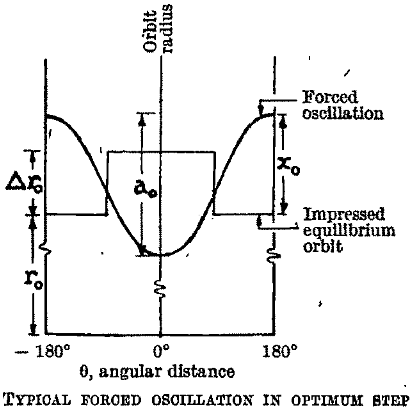

Fig. 1. Typical forced oscillation in optimum step field

Provided ΔH_0 is introduced so slowly that free oscillations are not excited, the motion of the electron is a forced one, repeating itself each revolution. Its maximum radial displacement x_0 from r_0 is given by

$$x_0 = \Delta r_0 \sin \tfrac{1}{2}K\theta_1/\sin K\pi\,; \qquad (3)$$

and the overall amplitude of the forced oscillation by

$$a_0/x_0 = (\sin K\pi)\,(\tan K\pi/2 - \tan K\theta_1/4). \qquad (4)$$

Now the reactive power required to build up the disturbing field, ΔH_0, in a fixed time is proportional to $\theta_1(\Delta H_0)^2$ and, therefore, using (2) and (3) we have, for the power required to produce a given x_0,

$$P = \tfrac{1}{2} P_1 (\sin^2 K\pi)\,(\theta_1/\sin^2 \tfrac{1}{2} K\theta_1), \qquad (5)$$

where P_1 is a constant. P is minimum when

$$K\theta_1 = 133^\circ\, 34', \qquad (6)$$

which gives for the minimum power:

$$P \doteq 1{\cdot}37\, P_1 (\sin^2 K\pi)/K. \qquad (7)$$

It will be seen that (6) defines an angle $\theta_1 \leqslant 360^\circ$ provided $0{\cdot}37 \leqslant K \leqslant 1$. If $0 \leqslant K < 0{\cdot}37$, however, 360° must be taken as the optimum attainable value for θ_1, and (7) is replaced by

$$P = \pi P_1. \qquad (8)$$

To assess the value of the above considerations, the power required to produce the same x_0 has been calculated for two other ejection methods. For the 'orbit-expansion' method we have, clearly, as in (8)

$$P' = \pi P_1 \;\ldots\; 0 \leqslant K \leqslant 1; \qquad (9)$$

while, for the '+ − field' method, the equivalent of equation 3 is $x_0 = \Delta r_0\,(\sec \tfrac{1}{2} K\pi - 1)$, which leads to

$$P'' = (4\pi/(\sec \tfrac{1}{2}K\pi - 1)^2) P_1 \;\ldots\; 0 \leqslant K \leqslant 1. \qquad (10)$$

These powers are compared in Fig. 2, from which the advantage of an optimum step-field is clear.

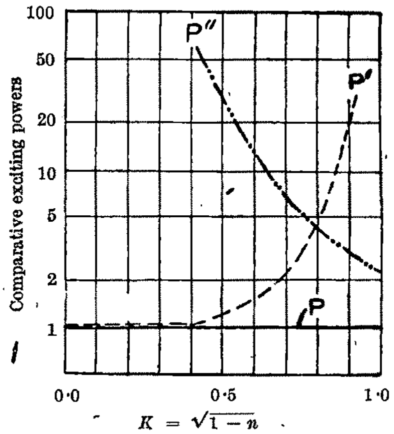

Fig. 2. Comparative powers for given displacement

In most cases, reactive power considerations will be the only important ones and the optimum step field will be used. However, in the particular case of using an external injection gun and extractor (say, a magnetic shunt[1]), both in the plane of the electron orbits, the forced oscillations are used to clear the injector during extraction. It will be seen from equations 4 and 6 that the overall amplitude of the forced oscillations, a_0, is $\geqslant x_0$ provided $1 \geqslant K \geqslant 0{\cdot}68$. In this range, therefore, the optimum step field gives the same clearance as the '+ − field', for in the latter case, although a_0 is always equal to $2x_0$, the undisturbed equilibrium orbit only clears the extractor by x_0. For $0 \leqslant K < 0{\cdot}68$ the clearance with the optimum field method is less than with the '+ − field' method, for example, at $K = 0{\cdot}55$ it is $0{\cdot}5x_0$. In general, however, sufficient clearance can be obtained still maintaining high power efficiency, by using a step field of less than optimum length.

This work was carried out by the Atomic Energy Research Establishment Group at the Telecommunications Research Establishment, Malvern, and acknowledgment is made to Dr. J. D. Cockcroft for permission to publish these results.

Structure of Graphite

THE recent communication in *Nature*[1] by J. Gibson directing attention to new extra lines in the X-ray powder diffraction pattern of graphite led us to re-examine a number of photographs of purified natural and artificial graphites taken some time ago. There appeared to be no extra lines in the positions observed by Gibson, although there were some exceedingly faint ones in other positions.

It seemed to us important to attempt to test the validity of Gibson's findings, because, if his extra lines were genuine, certain important modifications of the structure of graphite would be necessary. Our conception of the variations which may possibly occur in the graphite structure would permit the observation of weak extra lines at angles higher than that of the $10\bar{1}0$ reflexion from hexagonal graphite but would preclude any others, unless periodic inclusions are present. Now Gibson's strongest extra lines are precisely these 'forbidden' low-angle (high-spacing) deflexions.

If these structural variations are not present in appreciable proportions, the origin of the extra lines must be connected with the presence of impurities either in the specimen or in the spectrum of the X-radiation used in producing the pattern. To test the first possibility, Dr. Gibson very kindly sent us some of his purified (but not heat-treated) Ceylon graphite; its ash content was stated to be 0·07 per cent. A photograph was taken of this specimen, supported in a flat, 0·03-mm. thick, 'Cellophane' holder in an 11·5-cm. diameter Seeman–Bohlin focusing camera using cobalt $K\alpha$ radiation reflected from a bent quartz monochromator. No extra lines were seen other than weak rhombohedral lines. We also took ordinary Debye–Scherrer powder photographs in a 9-cm. camera using copper $K\alpha$ radiation reflected from a plane pentaerythritol crystal, and again observed no 'extra' lines other than those corresponding to the rhombohedral structure.

This suggested that the filtered radiation used by Gibson probably contained substantial amounts of wave-lengths other than cobalt $K\alpha$, and a more detailed examination of the θ values given by Gibson in his note confirmed this supposition. When the wave-lengths of the first six lines were calculated from the Bragg relationship assuming reflexion from the 0002 planes, it was seen that they agreed well with wave-lengths of various metals; reflexion of these same radiations from other graphite planes accounted for the remaining ten lines.

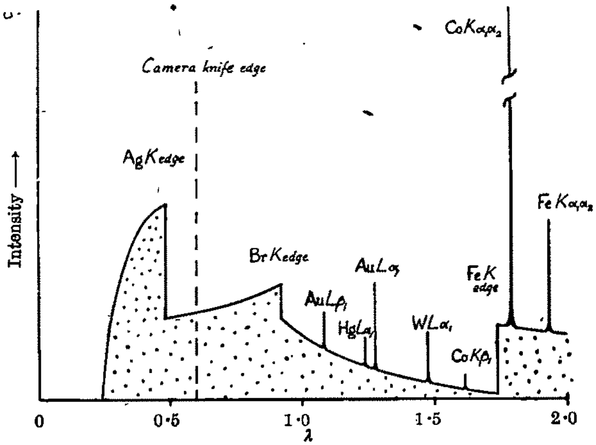
* Doublet.

† Calculated from the values of the cell dimensions of graphite obtained by Nelson and Riley[4].

‡ Taken from Siegbahn's "Spectroscopy of X-rays" (Oxford University Press, 1925).

It appears clear from the table that Gibson's extra lines can be attributed to the presence of small amounts of iron, gold, mercury and tungsten in the cobalt target plating. The fact that only the lines arising from the basal plane reflexions are doubled lends support to this conclusion, as these reflexions only are usually doubled in ordinary powder photographs of graphite[2]. It will be noticed that a number of lines which should be present have apparently not been observed by Gibson. In most cases this is due to their coincidence or close proximity with either strong cobalt $K\alpha$ lines (Au$L\alpha_1$ from $21\bar{3}1$, W$L\alpha_1$ from 0004, Fe$K\alpha$ from 0004, $11\bar{2}2$ and $11\bar{2}0$, Hg$L\alpha_1$ from $11\bar{2}0$ and $21\bar{3}1$) or with the impurity radiation lines themselves (Hg$L\alpha_1$ from 0004 and $11\bar{2}2$). The iron filter used to reduce the intensity of the cobalt $K\beta$ does not appear to have been chosen of optimum thickness. Moreover, the use of an aluminium screen in front of the photographic film is a practice which accentuates the effects of harder radiation[3] and does not in general reduce 'back-ground scatter'. The effect on the photographic films of the wave-length/intensity distribution of the radiation used is probably something like that shown in the accompanying figure.



PROBABLE EFFECTIVE SPECTRAL DISTRIBUTION OF THE RADIATION USED

For most X-ray diffraction work, carefully filtered radiation is perfectly adequate. However, it is clear from this work that for the detection of second-order effects, slight amounts of extra phases, or for the examination of disordered or amorphous substances, the use of crystal-reflected radiation is essential, if the introduction of spurious detail into the diffraction pattern is to be avoided.

It is interesting to observe here that with the ordinary 19-cm. diameter powder camera, together with a specimen rod of a pure substance giving well-spaced strong reflexions, it is a comparatively simple matter to test the purity of the filtered X-ray beam.

A RECENT communication by Gibson[1] sought to show that X-ray powder photographs of graphite contained 'extra' reflexions that could not be explained on the basis of the co-existence of the hexagonal and rhombohedral structures described by Lipson and Stokes[2]. It is of some importance that the crystal structure of graphite should be correctly specified[3], and, because of our experience in examining by X-ray methods graphites from many different sources, we have thought it useful to investigate the validity of the observations made by Gibson. Besides the particular problem of the structure of graphite, there are also involved some questions of X-ray technique on which comment appears called for.

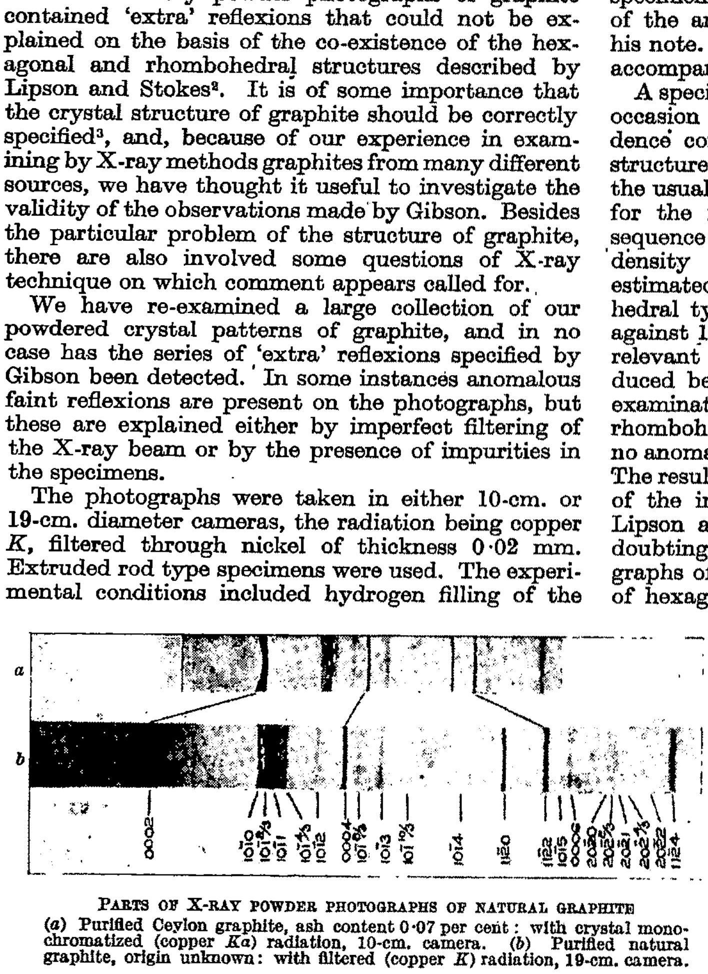
We have re-examined a large collection of our powdered crystal patterns of graphite, and in no case has the series of 'extra' reflexions specified by Gibson been detected. In some instances anomalous faint reflexions are present on the photographs, but these are explained either by imperfect filtering of the X-ray beam or by the presence of impurities in the specimens.

The photographs were taken in either 10-cm. or 19-cm. diameter cameras, the radiation being copper *K*, filtered through nickel of thickness 0·02 mm. Extruded rod type specimens were used. The experimental conditions included hydrogen filling of the camera to reduce background scatter, but not an aluminium screen, as it is considered that no advantage is to be gained from the use of even a thin screen with such materials as graphite. The photographic density of the films appeared in every way comparable with that of Gibson's, with the background clear enough to provide favourable conditions for detection of weak lines, should they occur. The change from cobalt to copper radiation cannot be regarded as significant, for we see no reason to suppose that reflexions appearing with one radiation are likely to be suppressed when the other is used. Most of the patterns showed a faint 0002β line, attributable to the imperfect filtering action of the nickel absorbing screen; the identification of this line is a simple matter.

In order that we could rule out the possibility that our samples of graphite did not include every variant, Dr. Gibson kindly sent us specimens of two of the powders which he had used. One of them was the purified natural graphite with ash content 0·07 per cent; the other was an artificial graphite of ash content 0·05 per cent. We were also concerned to avoid any remaining ambiguities concerning the character of filtered X-radiation, and so these two specimens and a few of our own have been examined with copper *K*α radiation obtained with a flat crystal monochromator of the type described by Lipson, Nelson and Riley[4]. With a 10-cm. diameter camera, hydrogen-filled during the photographic exposure, all specimens have given X-ray patterns showing none of the anomalous reflexions specified by Gibson in his note. One of these patterns is reproduced in the accompanying figure.

A specimen of graphite which we have recently had occasion to examine provides some additional evidence concerning the hexagonal and rhombohedral structures. The X-ray powder photograph contains the usual lines for both structures, but the reflexions for the rhombohedral form, characterized by the sequence *ABCABC* . . ., are of appreciably greater density than has been noted previously. It is estimated that as much as 25 per cent of the rhombohedral type of graphite occurs in this specimen, as against 10–15 per cent in most other specimens. The relevant part of the powder photograph is reproduced below. The significant feature of the X-ray examination is that, although so many lines for the rhombohedral structure appear of enhanced strength, no anomalous or forbidden reflexions can be detected. The result provides strong confirmation of the validity of the interpretation of the X-ray data given by Lipson and Stokes. There seems little reason for doubting that all features of X-ray powder photographs of graphite are explained by the co-existence of hexagonal and rhombohedral forms.

In conclusion, we would endorse the remarks made by Nelson and Riley in the accompanying letter. Filtered *K*-radiation certainly provides an effective 'monochromatic' beam for general purposes. Our experience is that it is reasonably satisfactory for the examination of graphites, provided the target material is carefully selected and the X-ray set is kept in good condition. But the limitations have to be recognized, and when structural details of the type in question have to be investigated, the final test must reside with a crystal-monochromatized beam.



PARTS OF X-RAY POWDER PHOTOGRAPHS OF NATURAL GRAPHITE
(*a*) Purified Ceylon graphite, ash content 0·07 per cent: with crystal monochromatized (copper *K*α) radiation, 10-cm. camera. (*b*) Purified natural graphite, origin unknown: with filtered (copper *K*) radiation, 19-cm. camera.

As Nelson and Riley point out, a reflexion of the intensity of the 0002 reflexion from graphite does, in fact, provide a good means of analysing the spectrum of the X-ray beam employed.

Phase-Contrast in the Photomicrography of Metals

The method of phase-contrast[1] has been successfully applied in this Laboratory to the 'vertical' illumination metallurgical microscope.

In the course of studies on the microstructure of alloy steels, heat-treated to show "intermediate transformation products"[2], photomicrographs of the ordinary type, such as Fig. 1, have been obtained from samples etched with nitric acid in alcohol. These show areas of two materials, the martensite representative of the transformed austenite and the "intermediate transformation product"; but owing to their similar light-reflecting properties, it is not always easy to distinguish them from one another, and the most prominent features are simply the black lines indicating their mutual boundaries.

Electron micrographs of the same specimen, such as Fig. 2, produced from negative ('Formvar') replicas[3], give higher resolution, but, in addition, show greatly improved contrast between the martensite and the "intermediate transformation product". The latter has been attacked more rapidly by the nitric acid, and its surface-level is therefore below that of the martensite; but whereas the electron microscope technique is very sensitive to this change in level, the normal light microscope does not appreciate it.

These characteristic differences in level should give rise to characteristic differences in phase in light reflected from the metal, and the phase-contrast method will convert such differences in phase into observable differences in light intensity. (A complicating factor is the possibility of differences in phase change on reflexion depending on the varying nature of the areas as distinct from their varying levels.)

A 'vertical' illumination microscope with specially designed phase-contrast modifications has been set up, and Fig. 3 is a phase-contrast photomicrograph obtained from it. There is a very clear distinction between the "intermediate transformation product" (dark areas) and the martensite (light areas), and the general correspondence between the tone values in this phase-contrast photomicrograph and those in the electron micrograph of Fig. 2 is noteworthy.

Fig. 1

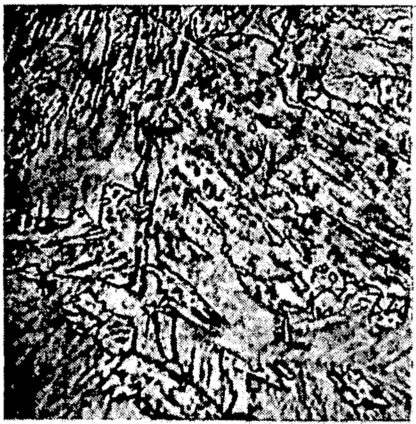

Fig. 2

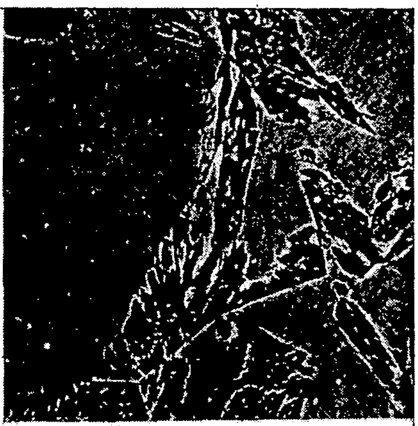

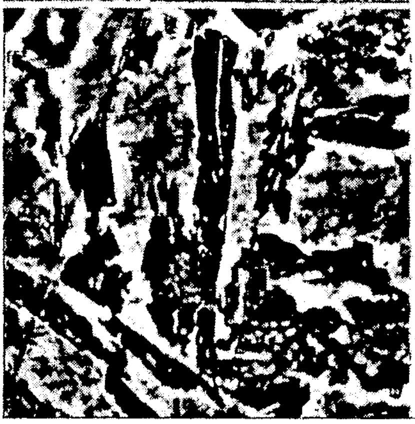

Fig. 3

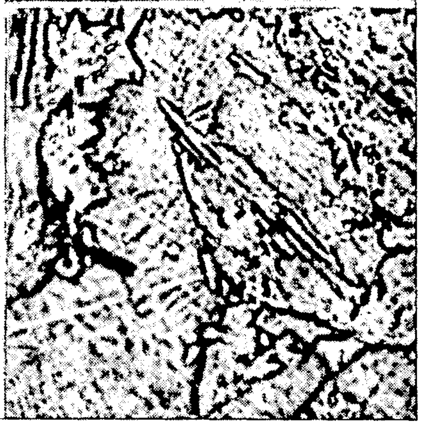

Fig. 4

Fig. 1. Normal photomicrograph
Fig. 2. Electron micrograph
Fig. 3. Phase-contrast photomicrograph
Fig. 4. Photomicrograph control for Fig. 3. × 1,600

Since contrast-levels can so easily be adjusted photographically by suitable choice of plates and printing papers, Fig. 4 is included as a 'control' on Fig. 3. It shows yet another area of the same specimen taken with the same objective lens (42-mm. oil immersion) and with the same photographic materials as the phase-contrast photomicrograph of Fig. 3, but *without* phase-contrast and at a somewhat reduced aperture.

Direct observation on the 'vertical' illumination phase-contrast microscope therefore provides valuable information previously only obtained indirectly through the agency of replicas and photographic means on the electron microscope. Such direct observation is a very valuable feature, and it is therefore felt that this development places in the hands of metallurgists and others interested in surface structures a new tool of considerable interest.

Further details will be published elsewhere.

The work described here has been carried out as part of the general research programme of the National Physical Laboratory, and this note is published by permission of the Director of the Laboratory.

The photomicrograph of Fig. 1 was prepared by Mr. J. L. Heslegrave and the electron micrograph of Fig. 2 by Mr. J. Trotter.

Felting of Animal Fibres

WHEN a mass of loose wool or fur is rubbed in presence of an aqueous solution of acid or alkali, a felt is produced because the surface scale structure of the fibres causes them to migrate in the direction of their root ends. In the preparation of rabbit fur for felting, it is customary to treat the tip ends of the fibres, before the skin is cut away, with a solution of mercuric nitrate in nitric acid. The process, known as 'carroting', has the effect of enhancing the felting power of the fibres, and similar results can be obtained with other oxidizing agents, such as hydrogen peroxide, in presence of suitable catalysts. In all cases, the essential reaction is disulphide-bond breakdown, which was believed to be beneficial[1] because the tip ends of rabbit fibres are coarser than the roots. After treatment, the tips of the fibres are much less resistant to deformation, with the result that they are able to follow the finer root ends through entanglements which would otherwise have obstructed further movement and felting.

Although the process of 'carroting' is centuries old, its exact purpose has only recently been recognized[1], and no attempt has been made, therefore, to enhance the felting power of fur fibres by using reducing agents, instead of oxidizing agents, to cause disulphide-bond breakdown in the tips. It has now been found that treatment with a 10 per cent solution of sodium metabisulphite in aqueous alcohol[2] for one hour at 50° C. is particularly effective, even with wool fibres, which are uniform in diameter along their length.

Locks of 58's Australian cross-bred wool were treated with sodium metabisulphite over various fractions of their lengths, starting from the tip, 'carded', and then felted (4-gm. samples) for 30 minutes in presence of soap in a model felting machine[3]. The results are given in Table 1, where the degree of felting is indicated by the value of the 'compression resistance', which is the ratio of the thicknesses of the felted pad under standard high and low pressures. Maximum felting is obtained when half the length of the fibres, starting from the tip, is treated with sodium metabisulphite.

TABLE 1

Reagent	Fraction of lock treated	Compression resistance
Sodium metabisulphite	None	0·717
	Tip ¼	0·814
	Tip ½	0·826
	Tip ¾	0·720
	Whole lock	0·609

It is obvious that such a high degree of entanglement as exists in a finished felt could not be brought about unless the root ends of migrating fibres are sufficiently rigid to force a way through entanglements made in earlier stages of the felting process[4]. This is, no doubt, the reason why the degree of felting is least when the whole fibre is treated with sodium metabisulphite. As, however, the flexural rigidity of intact wool fibres is low, it seemed likely that improved felting might be obtained by hardening the root ends of fibres instead of softening the tips. This deduction was confirmed by treating locks of wool with a solution of mercuric acetate ($0{\cdot}1M$) in acetic acid ($0{\cdot}1N$) for one hour at 25° C. Mercuric acetate is by far the most effective cross-linking agent for animal fibres[5], and the results obtained with wools which were cross-linked over various fractions of their lengths, starting from the root end, are given in Table 2.

TABLE 2

Reagent	Fraction of lock treated	Compression resistance
Mercuric acetate	None	0·717
	Root ¼	0·761
	Root ½	0·694
	Root ¾	0·545
	Whole lock	0·387

The highest degree of felting is obtained when about a quarter of the length of the fibres, starting from the root end, is treated with mercuric acetate.

As would be expected, there is a dramatic rise in the felting power of animal fibres when hardening of the root ends is combined with softening of the tips, and this principle is likely to form the basis of the 'carroting' processes of the future. At present, the best practical means of carrying out such processes seems to be to harden the whole fibre with cross-linking agents and then to soften the tip by means of reagents which cause disulphide-bond breakdown.

We are indebted to the International Wool Secretariat for grants in aid of the investigation.

Total Emission Noise in Diodes

C. N. SMYTH[1] has shown that the space-charge between anode and cathode in the cut-off region of a diode gives rise to a large input conductance $1/R$ at ultra-high frequencies. He has also put forward arguments that the space-charge behaves as an additional source of noise at ultra-high frequencies. Hence it might be worth while to measure the 'equivalent noise temperature' T_e of the conductance $1/R$, T_e being defined by

$$\overline{i^2} = \frac{4k\,T_e\,\Delta\nu}{R}, \qquad (1)$$

in which $\overline{i^2}$ denotes the mean square noise current in a frequency interval $\Delta\nu$ and k is Boltzmann's constant.

Measurements were carried out at 7·25 m. wave-length on a diode having an emitting cathode area of about 10 cm.[2] and an anode-cathode distance of 0·1 cm., using a saturated diode as a standard noise generator. In this way we were able to measure the input damping $1/R$ as well as the equivalent saturated diode current I_e, defined by the relation :

$$\overline{i^2} = \frac{4k\,T_e\,\Delta\nu}{R} = 2e\,I_e\,\Delta\nu, \qquad (2)$$

where e is electronic charge.

The results are shown in Figs. 1 and 2. In Fig. 1 $1/R$ is plotted against V_a, in Fig. 2 I_e against V_a for a heater voltage $V_f = 12$ V., as well as for $V_f = 8$ V. It is shown in Fig. 2 that the equivalent noise current I_e is much larger than the anode current I_a.

Measurements of the characteristic showed that the saturation currents for $V_f = 12$ V. and for $V_f = 8$ V. differed by a factor 50. $1/R$ and I_e are only slightly dependent upon the saturation current I_s ; a change in I_s by a factor 50 corresponds to a change in $1/R$ and I_e by about a factor 3.

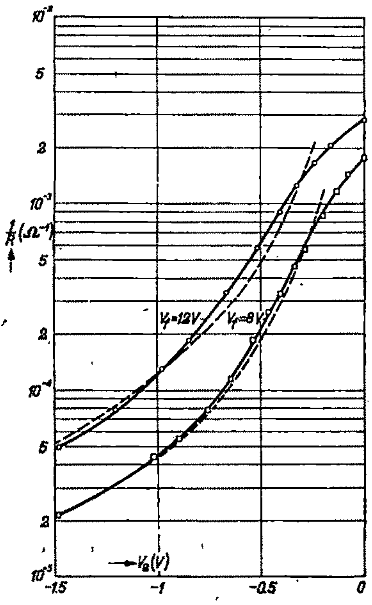

Fig. 1

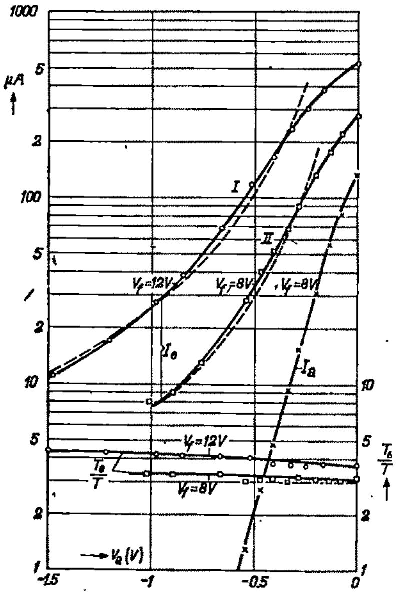

Fig. 2

Fig. 1. $1/R$ AS A FUNCTION OF V_a FOR HEATER VOLTAGES OF 12 V. AND 8 V.

Fig. 2. I_e, I_a AND T_e/T AS A FUNCTION OF V_a FOR HEATER VOLTAGES OF 12 V. AND 8 V.

$1/R$ and I_e are approximately proportional to V_a^{-2}. This follows directly from Figs. 1 and 2, in which dotted curves $C\,V_a^{-2}$ are drawn ; the values of the constant C are chosen such that each dotted curve coincides with the corresponding full-drawn curve at $V_a = -1{\cdot}0$ V. As T_e is proportional to $I_e R$, we should expect T_e to be approximately independent of V_a. This is shown in Fig. 2, in which T_e/T (T denoting normal room temperature = 290° K.) is plotted against V_a for $V_f = 12$ V. and for $V_f = 8$ V.. According to these curves, the average values of T_e at $V_f = 12$ V. and at $V_f = 8$ V. are approximately equal to 1,200° K. and 900° K. respectively; this nearly coincides with the actual cathode temperature.

Hence our final result is that the total emission noise may be described by assuming the 'equivalent noise temperature' T_e of the conductance $1/R$ to be equal to cathode temperature. It is to be expected from a theoretical point of view that this result will hold for a very wide frequency range, because $1/R$ and I_e are both proportional to the square of the frequency.

A fuller account of our investigations will be published elsewhere.

Polarization of Infra-Red Radiation

A METHOD of making thin selenium films with free surfaces has been devised, and this has enabled us to construct a pile of selenium films which polarize a beam of radiation falling on the plates at the appropriate angle. The transmitted beam is the one which is used, and a high degree of polarization (with very little loss of efficiency) is obtained with only three films. The films are not perfectly flat; since, however, they are only a few microns thick, this introduces no distortion in the transmitted beam, and is of service in eliminating the loss of polarization due to multiple reflexions. The films show a small absorption at a wave-length of 2 μ, but are otherwise transparent so far as we have examined them (about 7 μ).

Some interesting cases of pleochroism in sucrose have been reported by Ellis and Bath[1], who observed the absorption of radiation polarized by a Glan–Thompson calcite prism in the very near infra-red (up to 1·7 μ). This method restricts observation to the overtones of the molecular vibration bands which occur in this region. The selenium polarizer, however, can be used over a wide range of wave-lengths in the infra-red spectrum. We have made preliminary experiments to determine how the intensity of absorption depends on the orientation of the molecule with respect to the plane of vibration of the incident radiation. Marked effects have been found in the absorption spectrum of naphthalene (a crystalline material) and of nylon (an oriented film of a linear polymer). For example, in naphthalene, with the direction of propagation of the incident radiation perpendicular to the plane containing the *a* and *b* axes, and the electric vector parallel to the *b* axis, the absorption of bands at 3·3 μ, 2·1 μ, and 2·2 μ is considerably stronger than when the electric vector is parallel to the *a* axis. Other bands in this region are not affected. In the case of nylon, the absorptions between 3 μ and 3·2 μ corresponding to stretching the CH and NH bonds are more intense when the incident light vector is perpendicular to the direction of the stretched chains. This is in harmony with current ideas on the structure of nylon. We have also observed differences in the relative intensities of bands in the region 6 μ to 7 μ.

It is expected that the use of polarized infra-red radiation will be of service in identifying absorption frequencies with particular modes of vibration of the molecule, and in correlating the direction of valence links with the external surfaces of oriented materials.

A Spherically Symmetrical Non-Static Electromagnetic Field

WE have recently found the most general non-static solution of spherical symmetry satisfying the relativistic equations of electromagnetism, namely,

$$G_{\mu\nu} - \tfrac{1}{2}GJ_{\mu\nu} = -8\pi T_{\mu}^{\nu}, \quad (1)$$

where

$$T_{\mu}^{\nu} = -F^{\nu\sigma}F_{\mu\sigma} + \tfrac{1}{4}\delta_{\mu}^{\nu}F^{\alpha\beta}F_{\alpha\beta}, \quad (2)$$

$$F_{\mu\nu} = k_{\mu,\nu} - k_{\nu,\mu}, \quad (3)$$

$$F^{\mu\nu}{}_{,\nu} = J^{\mu}, \quad (4)$$

in the usual notation[1]. The line element is

$$ds^2 = -(1 - 2m/r)^{-1}\,dr^2 - r^2\,(d\theta^2 + \sin^2\theta\,d\varphi^2) + \dot{m}^2\,(1 - 2m/r)/f^2.dt^2, \quad (5)$$

where

$$f \equiv f(m) = m'(1 - 2m/r), \dot{m} \equiv \partial m/\partial t, m' \equiv \partial m/\partial r. \quad (6)$$

The surviving components of the tensor T_{μ}^{ν} are four:

$$-T_1^{\,1} = T_4^{\,4} = m'/4\pi r^2,\ T_1^{\,4} = m'^2/4\pi\dot{m}r^2,\ T_4^{\,1} = -\dot{m}/4\pi r^2. \quad (7)$$

If we interpret T_{μ}^{ν} as

$$T_{\mu}^{\nu} = \rho v_{\mu}v^{\nu},\ v^{\mu}{}_{,\nu}v^{\nu} = 0, \quad (8)$$

and define

$$\frac{d}{d\tau} \equiv v^1\frac{\partial}{\partial r} + v^4\frac{\partial}{\partial t}, \quad (9)$$

$$v^1 = \sqrt{f(m)/4\pi\rho r^2}, v^2 = 0, v^3 = 0, v^4 = -m'v^1/\dot{m}, \quad (10)$$

$$dm/d\tau = 0, dv^1/d\tau = 0, d(4\pi r^2\rho)/d\tau = 0. \quad (11)$$

Both ρ and $f(m)$ are arbitrary. We note that m is conserved along a line of flow.

It is interesting to note that there are several solutions of (3) and (4) consistent with (5). One solution is given by

$$k_1 = -\frac{m'}{\sqrt{(4\pi f)}}\cos^{-1}(\sin\theta\sin\varphi),$$
$$k_2 = 0,\ k_3 = 0, \quad (12)$$
$$k_4 = -\frac{\dot{m}}{\sqrt{(4\pi f)}}\cos^{-1}(\sin\theta\sin\varphi).$$

$F_{\mu\nu}$ and J^{μ} can be readily calculated. Results corresponding to (10) and (11) follow for this interpretation of T_{μ}^{ν}. All such solutions and their details will be published elsewhere.

The line element (5) was first published by one of us[2] some years ago. A line element equivalent to (5) but not obviously so was obtained by Mineur[3] several years earlier. No attempt, however, seems to have been made to obtain the electromagnetic interpretation of the line element in terms of k_{μ} and J^{μ}.

Existence of New Types of Wakes Behind a Moving Body

A QUESTION which to me seems very interesting was posed by Dr. Christopherson in *Nature* of March 8, p. 345: Can an approximate (numerical) computation establish either the existence or non-existence of a mathematical solution? He was describing a recent use of relaxation methods to find new types of wake behind a moving body, and expressed himself as satisfied that these exist. But the paper which recorded these computations also recorded failure to discover behind a 'planing surface' a motion of the fluid involving waves. This failure had not been expected, and Dr. Christopherson concludes (as I think, rightly) that it should be regarded as a null result from an ideal experiment.

For my own part, though I believe in the existence of finite wakes, I should do so with less confidence if the only evidence were the solutions which Miss Vaisey obtained on the basis of finite differences; for if the down-stream junction had been one of two streams impinging at a small angle, then (as was remarked to us by Sir Geoffrey Taylor) a small 'splash' would have been directed upstream from the junction, and this might have been so small as to escape detection (its thickness might have been smaller than our mesh-length). On that account, in the paper, an argument for the existence of finite wakes was based on the 'membrane analogue' of inviscid motion. I think that a case was made; but what I should consider a more convincing argument would be some *exact* solution for a finite wake—and I am hopeful of finding one.

As regards the motion behind a planing surface, while agreeing with the view expressed by Dr. Christopherson I should, perhaps, correct his statement that what appears to be non-existent is a motion in which the depth is the same far upstream and far downstream of the plane. What we have sought without success is a motion involving waves downstream but not upstream. I do not think it would have been difficult to find a solution involving stagnation on both sides of the plane, and the same depth far away from it; but this would have little importance, for it would also entail an infinite velocity at the trailing edge. It must be emphasized that our paper dealt with an *inviscid* fluid, in which results of this kind are acceptable mathematically, with other conclusions still less in accord with experience. All our solutions, for example, would *in theory* hold with the velocities reversed.

Our paper, being concerned with computation, did not seem to be the place for physical speculation; but for my own part I suspect that friction plays an essential part in the production of waves behind a barrier or trailing surface. Perhaps some day we shall be able to test this conjecture by computations which take account of viscosity. I should be hopeful if I were sure that the wave motions are 'stream-line', but I suspect that the time-variable enters, and I see little prospect of handling three independent variables—at least, until machines become available.

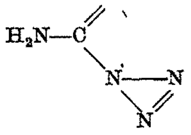
Coupling of Diazonium Complexes from an Aliphatic Base

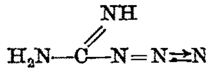
THE formation of diazonium complexes from unsaturated amines is not a unique property of the aromatic series. Many, but not all, unsaturated heterocyclic amines respond similarly[1]. With aliphatic amino-compounds, nitrous acid, under certain conditions, may give a diazo-grouping but not an ionizable diazo-derivative. In the literature it would appear that aminoguanidine is the only straight-chain compound so far recorded as being in line with the aromatic amines. Even in this example the tendency is to form an intermediate heterocyclic compound, and it is only under special conditions that a straight-chain diazonium derivative is obtained.

During some work on the action under different conditions of sodium nitrite on aminoguanidine, (*a*) a relationship has been found between the products formed, and (*b*) the nature of the resulting coupled-bodies also has been determined.

Thiele[2] treated aminoguanidine with sodium nitrite in the presence of free mineral acid and isolated a derivative which Hantzsch and Vagt[3] considered to be guanyl azide, with the structure shown in (I), but which in the light of modern resonance theory would probably be that in (II):



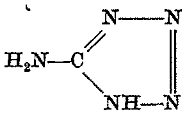
(I)



$$\mathrm{H_2N{-}\overset{\displaystyle NH}{\overset{\|}{C}}{-}N{=}N\rightleftarrows N}$$

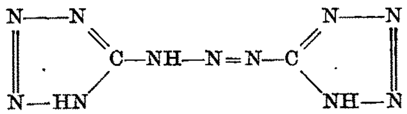
(II)

This azide, when treated with weak bases, isomerized to 5-amino-tetrazole:



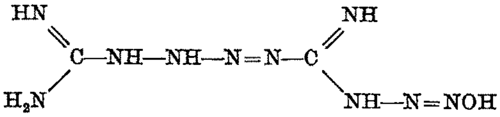
which when disazotized in the usual way gave a diazonium salt (*A*), which coupled with such intermediates as α- and β-naphthol to give azo compounds.

Hofmann and Hock[4] treated aminoguanidine with sodium nitrite in the presence of glacial acetic acid and isolated 1-3-ditetrazolyltriazene (*B*):



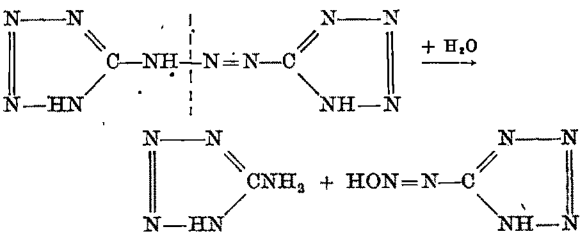
which when heated with a weakly alkaline solution of β-naphthol gave an orange-coloured solution.

The same workers[5] isolated 1-guanyl-4-nitrosoaminoguanylisotetrazene (*C*):

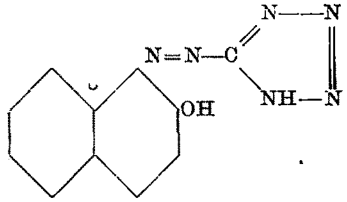


by the action of sodium nitrite on aminoguanidine in neutral solution. This also, under similar conditions, gave an orange-coloured solution with β-naphthol. This coloured compound was isolated from solution by Norris-Shreve, Carter and Willis[6], who showed that it possessed the properties of an azo dye.

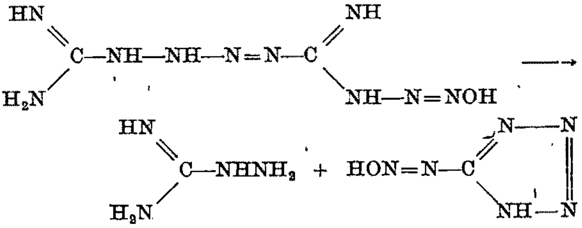
During the course of the present work, it was shown that the coloured compounds obtained with β-naphthol from each of the above three 'diazo' derivatives were identical in all respects. Their formation, however, proceeds differently. In *A*, the coupling takes place at ordinary temperatures with no evolution of nitrogen. In *B* and *C* the reaction is carried out at 80° C. In the case of *B*, splitting appears to occur at the $-\mathrm{NH}\vdots\mathrm{N}{=}\mathrm{N}-$ link, forming 5-amino tetrazole and diazotetrazole (diazonium hydroxide).



This diazotetrazole now couples with the β-naphthol in the α-position forming 1-2-3-4-tetrazole 5-azo-β-naphthol.



The case of coupling with 1-guanyl-4-nitrosoaminoguanylisotetrazene (*C*) is more complicated. Splitting takes place as in the case of *B* at the $-\mathrm{NH}\vdots\mathrm{N}{=}\mathrm{N}-$ link as indicated:



with the formation of aminoguanidine on one hand and diazotetrazole on the other, through ring closure as shown. The diazotetrazole couples, as in the case of *B*, if an intermediate is present. In the absence of a coupling intermediate, such as β-naphthol, the diazotetrazole loses two atoms of nitrogen, forming hydroxytetrazole.

To substantiate the structure of the foregoing β-naphthol complex, a series of reduction experiments were carried out on this substance. In all cases the products were found to be α-amino, β-naphthol and 5-aminotetrazole.

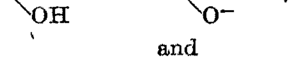
Relationships Between some Dissociation Constants

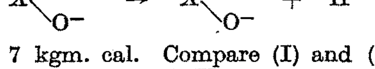
IN these Laboratories the fungistatic properties of ethylenic and acetylenic compounds have been studied recently[1]. Our results indicated that biological activity was connected with the presence of substituents that attract electrons strongly, and led us to a consideration of the dissociation constants of compounds which donate protons (that is, acids as defined in the broadest sense), since these constants form a basis for a comparison of the affinity for electrons of radicals and groups. During the course of this work, relationships were found between certain dissociation constants, which constants are conveniently expressed as ΔF $(= -RT.\log_e K)$[2] for the reaction $RH \rightarrow R^- + H^+$ taking place in dilute aqueous solution at 25° C. Although the relationships summarized below are of general application, space here does not permit them to be illustrated by long lists of examples, and so, as far as possible, only the values of ΔF (calories) for the seven acids, H_3PO_4 (I) + 2,900; $H_2PO_4^-$ (II) + 9,800; HPO_4^{--} (III) + 16,900; H_2SO_3 (IV) + 2,400[3]; HSO_3^- (V) + 9,800[3]; HSO_4^- (VI) + 2,300 and HOCl (VII) + 10,100[4,5], have been used in this discussion

(1) The values of ΔF for the two reactions



$$X\langle{}^{OH}_{OH} \rightarrow X\langle{}^{OH}_{O^-} + H^+$$

and



$$X\langle{}^{OH}_{O^-} \rightarrow X\langle{}^{O^-}_{O^-} + H^+$$

differ by 7 kgm. cal. Compare (I) and (II); (II) and (III); and (IV) and (V).

(2) The addition of a doubly bonded oxygen atom to the atom attached to a dissociating hydroxyl group decreases the value of ΔF by 7 kgm. cal.; for example, (V) and (VI). One of the two effects (1) and (2) in reverse should cancel out the other, and indeed (IV) and (VI) do agree within the limits of the experimental error.

(3) In the reaction $-Y-H \rightarrow -Y^- + H^+$, the combination of an additional proton with Y or the replacement of an atom directly attached to Y by another higher in atomic number by one unit decreases ΔF by 14 kgm. cal.; compare (III) and (VI). The difference, 14 kgm. cal., is so large that accurate measurement of both dissociation constants is usually difficult. However, the effect (3) can be reduced by combining it with (1) or (2), and the difficulty then disappears. The dissociation constant of a hydroxylic acid should, in fact, be unaltered if the atom attached to the hydroxyl group is moved back one place in the periodic table (ΔF changed by -14 kgm. cal.), and either: (*a*) two oxygen atoms are linked to the replacing atom by semi-polar double bonds $(+2\times 7)$ as in (V) and (VII); or (*b*) one oxygen atom $(+7)$ is attached and an extra proton is put on this oxygen atom $(+7)$ (examples are the pairs (I) and (IV) and (II) and (V)); or (*c*) two protons are added to oxygen atoms already attached to the replacing atom $(+2\times 7)$; (I) and (VI).

(4) In the reaction $-Y-H \rightarrow -Y^- + H^+$, the replacement of Y by an atom one higher in atomic number apparently decreases ΔF by 21 kgm. cal., at any rate when Y is carbon or nitrogen. This difference between the ΔF values is so large that it cannot be measured directly. However, ΔF for $AOH \rightarrow AO^- + H^+$ is greater than ΔF for $ANH_3^+ \rightarrow ANH_2 + H^+$. A comparison can be made with more than twenty different groupings for A, and the difference in the ΔF values is always close to 7 kgm. cal. This figure may be regarded as the net result of an increase in ΔF of 2×14 kgm. cal. due to the removal of two protons (effect 3) and a decrease of 21 kgm. cal. for the replacement of nitrogen by oxygen. This fourth effect is interesting because it suggests a means by which ΔF for carbon–hydrogen links can be estimated. For the dissociation of nitric acid, ΔF seems to be roughly $-1,000$ cal.[6]. From this by calculation for effects (3) and (4), ΔF for nitromethane should be $+13,000$ cal. The estimation of ΔF for nitromethane from that of nitramide $(+9,000$ cal.) leads to a figure of $+16,000$ cal. The experimental value of ΔF is $+15,000$ cal. The effect on the dissociation constants of pyridinium ions produced by substituents can now be used to throw light on problems of substitution in benzene derivatives.

This and other matters arising out of the discovery of these relationships will be discussed when a fuller account of this work is prepared for publication elsewhere.

Nature of the Tryptophanase Complex

IN a previous communication[1] we described th preparation of a cell-free extract of tryptophanas from *Esch. coli* and its resolution into a coenzym fraction and an apoenzyme.

The effect of various inhibitors was studied, a summarized below, and afforded information as t possible components of the enzyme complex.

Mepacrine. The inhibitory effect of mepacrine on the growth an tryptophanase activity of *Esch. coli* has already been announced[2] b Dawson, and this inhibition is antagonized by riboflavin.

Cyanide. *M*/50 potassium cyanide produces complete inhibition for 2 hr. and 93 per cent inhibition up to 18 hr.

Sodium Azide. A concentration of *M*/100 produces 50 per cent inhibition at 30 min.

Benzamide. *M*/1,000 produces 50 per cent inhibition, and this can be nullified by the addition of nicotinic acid.

Carbonyl Inhibitors. Hydrazine and hydroxylamine both give complete inhibition over the period of an hour, down to concentration *M*/1,000. Semicarbazide inhibits to 64 per cent at 30 min. with concentration *M*/100.

Dimedon is without effect on tryptophanase activity[3].

Carbon Monoxide. Produces 25 per cent inhibition at 30 min.

Hydrogen Sulphide. Produces 28 per cent inhibition at 30 min.

Sulphanilamide. (*a*) In culture. Complete bacteriostasis and hence non-production of tryptophanase at concentration *M*/43 (4 mgm./ml.). Using tenth dilutions, there was complete bacteriostasis at 24 hr. down to concentration *M*/4300 (that is, 40 μgm./ml.). (*b*) Viable washed cells. Sulphanilamide has no effect on preformed tryptophanase.

British Anti-Lewisite (*B.A.L.*), 2 : 3 dimercaptopropanol. At concentrations of *M*/10 and *M*/20 gives complete inhibition for 60 min., this effect decreasing with concentration until it is not manifest at all at *M*/1,000.

Effect of Verdoperoxidase. A preparation of verdoperoxidase from leucocytes was obtained by the method of Kjell Agner[4]. Although not a very active specimen, pronounced stimulation of tryptophanase activity was recorded. Catalase and polyphenoloxidase have both been found to be absent from our extract.

The dialysate from cell-free tryptophanase has been examined spectrophotometrically, and the type of absorption curve obtained corresponded most closely to that of pyridoxal phosphate. Spectrochemical investigation of an unpurified sample of apoenzyme revealed the presence of iron, but not of copper. A microbiological assay of both dialysate and apoenzyme has also been performed, using *Lactobacillus casei E*, and riboflavin has been shown to be present in both.

Reconstitution of Tryptophanase. Using inactive apoenzyme, the various possible coenzyme factors were added in turn and the effect noted. In this way we have been able to show that pyridoxal phosphate, riboflavin and diphosphopyridine nucleotide are each capable of reactivating the apoenzyme; stronger activation is obtained with pyridoxal phosphate plus diphosphopyridine nucleotide and with riboflavin plus the nucleotide, whereas maximum effect is obtained by the addition of all three.

Discussion. The study of the effect of various inhibitors on the activity of tryptophanase initially provided strong presumptive evidence for the nature of the enzyme complex. The mepacrine inhibition and its antagonism by riboflavin gave indication of the functioning of flavoprotein in the complex, this being substantiated by the subsequent identification of riboflavin as a coenzyme factor. The effect of cyanide, hydrogen sulphide and carbon monoxide suggests that a cytochrome-type of system is operating, though it is known from the work of Keilin and Harpley[5] that cytochrome *c* and cytochrome oxidase are absent from *coli*, and also that bands *b* and *c* of normal cytochrome are replaced by one band which lies at 560 mμ and which represents the α-band of non-autoxidizable hæmochromogen component b_1.

A component containing the aldehyde or carbonyl grouping seemed likely from the way in which characteristic carbonyl reagents inhibited tryptophanase activity, and this has been reconciled with the presence of pyridoxal phosphate. In a similar manner the inhibition produced by benzamide, and antagonized by nicotinic acid, could be related to interference with a pyridino component such as diphosphopyridine nucleotide.

The effect of verdoperoxidase is of considerable interest. It has been suggested by Keilin[6] and Kuhn[7] that verdoperoxidase might be considered as more or less modified cytochrome-*a* derivatives. In view of absence of the cytochrome-*c* – cytochrome oxidase system, the marked increase in production of indole from tryptophane by our cell-free enzyme system in the presence of verdoperoxidase is of significance. Since *B.A.L.* is an inhibitor of metal-containing enzymes, as shown by Webb and Van Heyningen[8], this is compatible with the presence of an iron-containing system such as verdoperoxidase.

We should like to express our gratitude to Dr. E. F. Gale for a gift of pyridoxal phosphate, to Prof. R. A. Peters for *B.A.L.*, and to the Medical Research Council for a grant-in-aid.

A Copepod Parasite of the Mussel New to the British Fauna

Mytilicola intestinalis is a worm-like copepod first found in 1902 by Steuer[1] in the intestine of the mussel *Mytilus galloprovincialis* from the Gulf of Trieste; since then, there have been a number of other records both from this mussel and *M. edulis*[2]. All these were from the Mediterranean area; but in 1939, Caspers[3] found it in mussels from the Bremerhaven–Cuxhaven area of the German North Sea coast, and, in February 1946, I found that mussels from the mouth of the River Blyth, Northumberland, were parasitized. More than 90 per cent of the Blyth mussels examined were found to be infected; in one case, 18 specimens were obtained from a single host.

All the records seem to have been obtained from estuarine zones: Caspers found, in his area, that while mussels from the estuaries were heavily infected, those from neighbouring purely marine zones were completely free: in the present case, mussels from Holy Island, the only purely marine bed on the Northumberland coast, were found to be uninfected. I hope to examine mussels from other estuaries in this area in due course.

Where the parasite was present, Caspers found that most mussels were infected, often heavily—he found 14 specimens in a single host. Finding it hard to believe that such a heavy infestation could have occurred in a short space of time, he considers that previously the parasite must have been overlooked. It is difficult to believe that the parasite could have been overlooked in the present case. Mussels from the Blyth have long been used in this Department as experimental material, often as a source of crystalline styles; as the parasite is quite large, adults being more than 1 cm. long, and fairly obvious because of their hæmoglobin, the search for the styles should have revealed their presence. But it would be very interesting to know whether, in fact, the parasite is a recent arrival to Great Britain; knowledge of its presence and, equally important, its absence, from estuarine mussels of other parts of the country would be invaluable, and I would be very grateful for information on this point.

The parasite should be very useful for teaching and other purposes, for the ease with which living *Mytilus* can be sent through the post means that, probably for the first time, a living parasitic copepod will be easily available to inland laboratories; mussels from the Blyth may be obtained from the Dove Marine Laboratory, Cullercoats, Northumberland.

Copper in Diatoms

Work undertaken in this Laboratory suggests that certain species of diatoms, which are the normal constituents of the slime film which forms upon a submerged surface in marine waters, contain copper, far in excess of the amount usually considered lethal for unicellular Algæ. (Half to one part per million is usually sufficient to remove algal growths from reservoirs.) Large colonies of marine diatoms were gathered freshly during the spring maximum of 1946, from a raft located in Chichester Harbour. Sixteen samples were examined: Nos. 1–12 inclusive were species which live in frondose colonies of mucous filaments, 5–10 cm. in length; samples Nos. 13–16 inclusive were species which grow either upon mucous stalks or embedded within a flat film.

After collection, the material was examined carefully and sorted into monotypic samples, care being taken to remove any contaminants such as filamentous seaweeds. The selected material was washed several times with filtered sea water, and examined for copper, using sodium diethyldithiocarbamate as an indicator. All samples gave a positive reaction, while samples 3–11 were submitted further to a quantitative estimation. The quantitative determination of copper was effected by the use of the absorptiometer method described by Haywood and Wood[1], with some special modifications. The selected material was washed free from salt and dried in a vacuum desiccator for 48 hours. Weighed portions of 0·5 gm. were wet-ashed; ammonium citrate was added in order to inhibit any iron that might be present, and strong solution of ammonia added, sufficient to produce an alkaline reaction. The mixture was then filtered to remove the siliceous skeletons of the diatoms, and the volume adjusted. Sodium diethyldithiocarbamate was added to a measured quantity of the mixture, which was allowed to stand for 15 minutes. The copper complex developed a yellow coloration, which was extracted by shaking with carbon tetrachloride, and estimated on a Hilger 'Spekker' absorptiometer.

The results showed that the diatoms contained from 31 to 164 parts per million of copper (weight/weight). The copper content of the sea water in which the diatoms lived was 0·007 mgm. per litre (7 parts per thousand million). It is not known in which form the copper is contained, but it is likely that it forms either an additive compound with the protein or alginin molecule within the diatom cell, and is thrown down as a coagulate or precipitate, or that it plays a functional part in the chromatophores.

Evidence from work upon cultures of diatoms without their siliceous frustules[2] indicates that the organisms can tolerate copper far in excess of that allowed by the range of solubility of copper in sea water of pH 7·92–8·2, which probably does not exceed 0·5 parts per million. It appears that the diatom forming so large a part of the slime which develops upon an underwater surface may be considered as a potential reservoir of copper, and in this way may play an important part in preventing the settlement of other and more sensitive fouling organisms.

Acknowledgment is made to the Board of Admiralty for permission to publish the foregoing work, which forms part of a general investigation in progress in this Laboratory on the anti-fouling problem relating to ships.

The New Lava from Hekla

On April 10 I received from Dr. Jóhannes Áskelsson of Reykjavik a specimen of the new lava from Hekla. Dr. Áskelsson states that the eruption began on March 29 at 7 a.m. (Icelandic time), and several lava streams began to flow in different directions. The specimen he sent was taken from the surface of the moving lava of a stream flowing east from the northern end of the Hekla ridge. It is a typical *aa* or block lava.

The rock is a dead black, highly slaggy basalt in which a few fresh white feldspars are entangled. In thin section the bulk of the rock turns out to be a brownish-black glass holding numerous swallow-tailed feldspar microlites, a few micro-phenocrysts of labradorite (Ab_1An_1), and still fewer of pyroxene and olivine.

This lava is identical with previous flows from Hekla, as I have ascertained by direct comparison with material collected by Sir George Steuart Mackenzie in 1810[1], which is preserved in the Hunterian Museum of the University of Glasgow. It is also identical with the Selsundhraun (*hraun*, Icel.=lava), a Recent flow 10 km. south-west of Hekla, of which I possess an unpublished analysis. This analysis agrees very closely with H. S. Washington's analysis of a Hekla lava from Nafrholt[2], and with Recent lavas from the Vatnajökull region[3]. All these magmas are slightly over-saturated with silica notwithstanding the early crystallization of a little olivine. It may therefore be concluded that the Recent basalt lavas of Iceland are very uniform in composition, and that there has been little or no change in that respect during the historical period.

RADIO AIDS TO MARINE NAVIGATION

ONE of the earliest applications of radio wave transmission was the introduction of a service whereby ships could be informed of their position under conditions in which ordinary visual observations or dead reckoning were not very reliable. For many years past, radio direction-finding stations on shore have supplied bearings to ships making special signals for the purpose; while many forms of direction-finder suitable for installation in ships have also been available, and could be used for observing the bearings of fixed radio beacons, which can easily be identified by the simple code signals emitted at regular intervals. During the past seven years, the growth and development of radio technique has been so rapid and so extensive that not only has a great deal of advance been made in the field of radio direction-finding as such, but also there has been devised and developed a number of alternative systems of using radio waves for fixing the position of a ship, whether it be in the open sea, near a coast or approaching a harbour. There are, in fact, so many possible systems of radio aids to marine navigation that it has become quite a difficult problem to decide which are the best or most appropriate for various applications. In order to reduce the number and variety of equipments to be carried by ships navigating in various parts of the world, it is clearly desirable that there should be some measure of international agreement on the matter.

It was with the view of providing scope for a full discussion of the value of these radio navigational aids, and of discovering to what extent they meet the requirements of the navigator and shipowner, that the Ministry of Transport organised an international meeting in London in May 1946 (see *Nature*, **157**, 689; 1946). The meeting was attended by some 120 delegates from twenty-three different countries, and a complete record of the proceedings of the meeting with its many lectures, demonstrations and visits has recently been compiled in two volumes by the Ministry of Transport and published by H.M. Stationery Office*.

The first volume provides a record of the proceedings of the conference with a full report of the discussions that followed the introductory lectures on the various systems, these lectures being given chiefly by the British naval officers and Government scientific workers who had been closely associated with the developments described.

The second volume contains the full text of the scientific and technical documents presented at the meeting, and comprises, in effect, a very full and up-to-date handbook dealing with the whole problem of marine navigation by means of radio transmission and reception. After introductory chapters on the needs of the mariner for navigational aids, and on radio wave propagation as it affects them, the volume goes on to examine in detail all the radio navigational aids in existence or under development. One section deals with all aspects of radio direction finding, both from ship and from shore, and including the different types of radio beacon. Another section covers hyperbolic systems of navigation, including Loran, Gee, Decca and other names familiar to many in the Services during the War. A large section is devoted to marine radar in all its forms, as a ship-borne instrument, as a shore installation for harbour supervision and in the form of radar beacons. This section also includes a specification for a ship-borne radar set, drawn up by combining a knowledge of the user's needs with a knowledge of the technical possibilities. This should prove of great value to the radar manufacturer and the shipowner, because both will know that a set conforming to this specification will be in every way satisfactory.

The development of transmitting compasses for association with radio navigational aids is dealt with, as is also the question of the provision of special charts in order to facilitate the work of the navigator in using the various aids. In the later portions of the volume an appreciation, with considerable technical detail, is given of the various devices discussed, and an important chapter speculates on the probable future trends of development.

This whole volume, which is well illustrated with diagrams and photographs, is essentially technical, and it contains a large amount of information unobtainable anywhere else. It will present many with their first picture of the far-reaching developments in radio navigational aids as a result of the War, and of the application of these developments to the safer and more efficient operation of ships at sea. It should prove of wide interest, and invaluable as a text-book to all who are in any way concerned with radio aids to navigation.

The publication of these two volumes is very opportune, and was in good time to pave the way for the continuation of the discussions at the recent international meeting in the United States of America.

ROLE OF STARCH IN LIGHT-INDUCED STOMATAL MOVEMENT, AND A NEW REAGENT FOR STAINING STOMATAL STARCH

By Dr. O. V. S. HEATH

**Research Institute of Plant Physiology,
Imperial College of Science and Technology,
London**

THE mechanism of the movement of stomatal guard cells in response to the stimulus of light, although under investigation for nearly a century, is still in doubt. The classical view[1] that such movements are due to changes of turgor has received support from many workers, who have found by plasmolytic methods that with stomatal opening the osmotic pressure in the guard cells increases[2-6]. More recently, the possible collaboration of a 'wall mechanism' in opening the stomata of *Cyclamen* and *Tradescantia* has been disproved[7], so that a turgor mechanism alone must be concerned; but how the changes in turgor are produced is still uncertain. Mainly owing to the work of Lloyd[8], Hagen[9], Loftfield[10] and Sayre[5] it is very generally accepted that they are due to hydrolysis or condensation of starch in the guard cells, probably brought about by enzyme action governed by pH changes in response to light. A careful examination of these and other relevant papers, however, shows that nearly all the evidence for such a mechanism is based on the observation of diurnal changes in starch content and stomatal aperture under natural conditions. These observations leave little doubt that, under such conditions, pore size and starch content are to a large extent, though by no means completely, negatively correlated. A similar inverse relation is shown where change of aperture is experimentally induced by altering the water relations of the leaf[2], or by immersing detached pieces of leaf or epidermis in various solutions[11–14]; but such data are not necessarily relevant to the problem of a light response. Where stomatal movement has been experimentally induced by changes of lighting conditions, at other than the natural times, the evidence for a correlation between starch content and stomatal aperture is not convincing[8,15]. The correlation of diurnal trends is an unsafe basis for a causal theory, especially in this case, since it has been shown that in cherry laurel[16] and *Pelargonium*[17,18] there is a diurnal rhythm of stomatal movement even under conditions of constant illumination. The diurnal rhythm of stomatal starch, which has not been shown to be due to light, may well provide the motive power for such autonomous stomatal movements.

---

* International Meeting on Radio Aids to Marine Navigation, May 1946. Vol. 1. Record of the Meeting and Demonstrations. 2*s*. 6*d*. net. Vol. 2. Radio Navigation: Radar and Position Fixing Systems for Use in Marine Navigation. 5*s*. net. (London: H.M. Stationery Office, 1946.)

Much of the uncertainty as to the relation between stomatal aperture and starch content arises from difficulties of estimation. Both stomatal apertures and guard cell starch show great variation between leaves and even on the same part of a single leaf. The measurement (usually by Lloyd's[8] method) of a sufficient number of stomata to give a satisfactory mean is tedious and seldom attempted, and errors in sampling procedure are probably common; for starch content no quantitative measure has been devised or seems possible, and subjective errors must be considerable. Furthermore, previous investigators have laboured under the great disadvantage of being unable to observe both aperture and starch simultaneously in the same stomata, because the aqueous iodine–potassium-iodide reagent used to stain the starch causes stomatal closure. This source of inaccuracy has now been overcome, for I have found that the reagent described below stains the starch very satisfactorily and causes no stomatal closure even in strips of epidermis that have been in absolute alcohol for a few days only. It has a very high refractive index, and excellent images may be obtained, either for visual work or photomicrography, by mounting the material in the reagent. The reagent is made by dissolving 2·5 gm. of iodine in 100 c.c. of phenol, containing the minimum amount of water necessary to make it liquid at room temperature and an excess of potassium iodide. The water-in-phenol solution may be conveniently obtained by leaving the stopper out of a bottle of pure phenol. The use of this reagent has made it possible to reduce subjective errors since photomicrographs showing both aperture and starch content may be compared. Photomicrographs of *Pelargonium* stomata have been taken which show approximately the same average starch content with relatively wide and relatively narrow apertures, in epidermal strips taken at the same time of day under conditions of light and darkness respectively. Here the possibility of diurnal rhythms in starch and aperture being concerned is eliminated. Photomicrographs from other experiments give evidence of increases in starch content without appreciable change of aperture, and even of decreased starch with decreased aperture.

Although the comparison of such photomicrographs reduces subjective errors and their publication will enable other workers to judge for themselves, the difficulties of taking representative samples and estimating mean values remain. If stomatal movement can be induced by light in the complete absence of starch, the matter rests on a more secure basis. I have been unable to find any starch (or chloroplasts) in the guard cells of onion stomata (*Allium cepa*, L.) either open or closed, thus confirming the observations of Parkin[19]. The investigations of Loftfield[10] using Lloyd's[8] method, showed that under natura conditions the stomata of the onion were motile but again an autonomous diurnal rhythm might have been concerned or a response to some external factor other than light. It has now been shown by porometer experiments that onion stomata respond in the normal way to light, and therefore this species at least has a light response which does not depend upon a starch $\rightleftharpoons$ sugar mechanism.

In view of the very diverse character of the numerous stimuli to which stomata respond it seems improbable that a unique mechanism is concerned, except to the extent that all responses must be due to turgor changes, and each type of stimulus will require separate investigation. For the present, only the response to light is under consideration, and here the evidence for a starch $\rightleftharpoons$ sugar mechanism seems inadequate.

This work will be published in detail elsewhere.

THE INVERNESS-SHIRE EARTHQUAKE OF DECEMBER 25, 1946

By Dr. A. T. J. DOLLAR
Department of Geology, University of Glasgow

AT about 17 hr. 2 min. (G.M.T.) on Christmas Day, 1946, an earthquake of maximum intensity VI (C. Davidson scale), accompanied by sounds, originated close to Spean Bridge in Inverness-shire, and was felt throughout much of central Scotland. Associated with it were at least two fore-shocks and one after-shock.

Postal reports received in response to appeals through newspapers, questionnaire-cards and radio broadcasts show that the disturbed area included the eight shires of Ross, Inverness, Perth, Argyll, Edinburgh, Clackmannan, Stirling and Renfrew. The region enclosed by a first approximation to isoseismal IV (C. Davison scale) is about 3,500 square miles. Extreme points from which such reports have been received, to date, are Muir of Ord in the north, Glasgow in the south, Edinburgh in the east and Tobermory, Isle of Mull, in the west.

The fore-shock of December 24, 1946, associated with the main quake, was felt not only in Inverness-shire and Argyll, but also as far south as Fenwick, Ayrshire.

The epicentre of this earthquake lies in the Inverness–Oban seismic zone, which includes the fracture-system of the Great Glen fault. Interest attaches to the fact that the recent tremors indicate stress-relief in a part of this zone where only one other earthquake of the same order of intensity has been recorded hitherto[1]. This latter was noticed at Gairlochy, Spean Bridge and Roy Bridge, over a period of six seconds, between 22 hr. and 23 hr. (G.M.T.) on August 22, 1924, when it attained a maximum intensity of IV (C. Davison scale).

Regarding the most recent activities at foci in the same zone, adjacent to Spean Bridge, records indicate that tremors originated near Inverness in September[2] and October 1901[3] and near Oban in both December 1925 and May 1941. Thus, between 1901 and 1947 foci have been active in the sequence: Inverness, Spean Bridge, Oban, Oban, Spean Bridge, suggesting a return of stress-relief to the central region of the zone after previous manifestations of this relief in the north, centre and south of the zone, respectively.

Times and durations noted in the epicentral region lead to the conclusion that the quake of December 25, 1946, began about 17 hr. 2 min. (G.M.T.) as a rumbling sound of low pitch which continued for about two seconds. This was followed by three sharp tremors, occurring over a period of about three seconds, the first of which exceeded the intensity of either of the others. The last tremor was followed by a further rumbling sound which became inaudible after about three seconds.

Close to the epicentre, effects of the three main tremors were compared to those of sudden explosions, such as the detonations of hand grenades. In a surrounding zone only one tremor was noticed, generally preceded, but not always followed, by a sound. Beyond this zone a weak tremor was felt, usually unaccompanied by any sound.

Some observers described sounds heard about the epicentre as being similar to the deep rumbling of a heavy vehicle passing over a bridge, or thunder, or gunfire at a distance. Others compared them to the oaring of wind, or to the noise of a train in a tunnel. At places remote from the epicentre, the sound was said to possess a harsh, rasping quality.

The intensity of this earthquake appears to have exceeded that of August 22, 1924, in the same locality (namely, IV (C. Davison scale)), for on this recent occasion not only were the chairs of several seated observers noticeably moved at Gairlochy and Spean Bridge, but also a plaster ceiling was thrown down in Achnacarry at the east end of Loch Arkaig; a chimney-pot dislodged from a house at the north-east end of Loch Laggan; two heavy shop-safes moved in Fort William, and windows, doors and rockery rattled at many places in the area. These, nd similar phenomena, are consistent with a maximum intensity of about VI (C. Davison scale). Further, the position and form of the central disturbed area, and distribution of intensities within it, uggest a close association of this earthquake with the Great Glen fault-system. On the other hand, resent information suggests there was no significant sympathetic movement in the Highland Boundary fault-system at or about the time when these recent Spean Bridge disturbances took place.

A weak fore-shock connected with this earthquake appears to have occurred at about 17 hr. 20 min. (G.M.T.) on November 19, 1946, and a second one close to 24 hr. (G.M.T.) on December 23, 1946. The latter, which was noticed in Inverness-shire, Argyll and north Ayrshire, consisted of two tremors lasting about four seconds and three seconds respectively, separated by an interval of about two seconds.

The after-shock of January 5, 1947, would seem to have taken place at about 09 hr. 35 min. (G.M.T.), when a slight rumble was heard in West Glen Roy and Glen Spean, having a duration of about three seconds.

INDUSTRY AND RESEARCH

CONFERENCE AT BIRMINGHAM

THE first of the regional conferences on "Industry and Research" sponsored by the Federation of British Industries was held at Birmingham on March 25. The morning session, over which Sir Ernest Canning, vice-president of the Federation, presided, was devoted to "Research and Economic Recovery", and Sir Ernest, in opening the Conference, emphasized the vital importance of research, not merely in the evolution of new materials, processes and products, but also in the improvement of existing processes and products. He pointed out that it is a vital factor in promoting the more effective use of materials, labour and power, thus saving coal and other fuels; and while in the short term we must all work harder, the only long-term method of restoring our pre-war standard of living lies in the persistent application of the scientific method and scientific advances to our industrial technique and life. We cannot equip ourselves for the highly competitive struggle in the world's markets which in two or three years will follow the sellers' market if we postpone the prosecution of industrial research until the time when the application of its results is essential to strengthen our competitive power.

In his paper on "Industrial Research and the National Economy", Sir William Larke commented on the document "Economic Survey for 1947" that in industry alone resides the power of making good the shortages and the responsibility of obtaining maximum production from the resources of fuel, raw materials and man-power which the Government is largely responsible for making available for industry. He urged that the scientific method must be applied throughout, starting at the level of the boards of directors. Sir William referred particularly to the possibilities in the saving of fuel by technical investigation and control, the economies in the use of raw materials and the reduction of waste often achieved by technical research, and the contribution of technological investigation of processes and machine operation to the increase in output per man-year. These are short-term measures for immediate application, but the long-term measures, including fundamental research, are in some ways an even more important factor. Sir William believes that the technical colleges have a more important part to play than in the past, and he emphasized the need for a spirit of inquiry and the development of research-mindedness as a national characteristic.

In the second paper at this session, Dr. J. W. Jenkin dealt with Midland industries and their research needs. These industries are exceedingly varied and multifarious; but there are some common factors, and whether the work be mechanical or scientific, real progress can only come from a ruthlessly objective study of all relevant facts and creative thinking to find relations between them and to devise the crucial experiments. There appears to be a need for a closer link between the scientific work characterizing the newer industries and the engineering inventiveness common in the older. This can often be supplied by making the same persons responsible both for the research results and their translation into practice. The bridging of the gap between the discovery and its commercial exploitation, the development stage, should not be left as a spare-time activity of those primarily responsible for administration, production or sales. Men are needed with wide sympathies to direct research away from over-emphasis on a restricted field of technology into closer liaison with development.

Sir Edward Appleton presided over the second session of the Conference, which dealt with industrial research in the Midlands. He commented on the increasing readiness of many scientific workers in universities and technical colleges to place their knowledge at the disposal of industry, but at the same time thought that the encouragement of co-operative action through the research associations is the most effective means of supplying the particular scientific knowledge which industry requires. Mr. F. G. W. King, technical director of the Dunlop Rubber Co., Ltd., contributed a well-documented paper on Midland research organisations, activities and facilities, in which he suggested that since most of the industrial research in this large and varied region is carried out in the laboratories of the large firms, although related contacts spread all over the country, investigation of methods of increasing productivity, particularly the skilled study of flow production, and close co-operation between research units and their related groups in firms, research associations and universities are required, in addition to further research. Such co-operation should be facilitated by fuller documentation of the broad fields of the research, to give a general idea of the problems studied, and he suggested that the research secretariat of the Federation of British Industries might help in the organisation of such documentation. Research, moreover, would only be fully effective if its results were known and appreciated by other experts and skilled workers in the industry. Appendixes to Mr. King's paper include an analysis of industries in the Birmingham region, and lists of industrial research in progress in technical colleges and universities, either in the region or outside the region, when specially related to its industries. The information relating to the universities was taken mainly from the "Notes on Current Scientific Researches in the United Kingdom" prepared for the Royal Society Empire Scientific Conference last year.

The concluding paper of the Conference, by Mr. J. C. Pearce, dealt with the smaller Midland firm and its application of research. Mr. Pearce suggested that the firm not large enough to provide one full-time or part-time technical man to act in liaison with outside developments should treat its research association as a source of information and apply for information as and when required. It should give the staff of the Association opportunities of assessing the nature of its work and problems so that replies can be suited to its ability to give effect to them. The research associations should treat this information from individual firms as strictly confidential, but use it to build up that part of the current research programme dealing with experimental work directed towards the solution of specific problems common to the industry as a whole or to sections of it. Mr. Pearce believes that the major functions of a research association, namely, the application of new knowledge through development and the dissemination of knowledge by intelligence activities, has been least satisfactorily solved.

In the discussion Mr. L. E. Lines, repudiating the suggestion that young industrial scientific workers should be excused military service, said that Great Britain is suffering from seeking too much security. Dr. Quarrel pointed out that this year we shall have only one fifth of the number of scientific recruits which was available to industry in 1938, and only one half of the average number for the war years. Sir William Akers, in summing up, said that some of the observations indicated that in certain directions planning by the Government has been very incomplete, and asked whether we should not now put all the technically and industrially fit people into the economic war.

OIL PLANTS IN EAST AFRICA

THE plan for mechanized production of ground nuts in East Africa described in the recent Whit Paper (Cmd. 7030) and the inherent importance o all oleaginous crops to-day give added interest to a informative and well-documented review of oil plant in East Africa by A. Glendon Hill, director of th East African Agricultural Research Institute (*E. Afr Agric. J.*, 12, 140; 1947). It deals with ground-nuts sesame and sunflower.

Ground-nuts. One of the most valuable of oil plants with an oil content of nearly 50 per cent in th shelled nuts, it is widely grown by natives in Eas Africa, mainly for their own food; though it ha not hitherto attracted the European farmer to an extent. In addition to oil, the nuts are rich in protein (about 30 per cent), so that after extraction o the oil the press cake forms a valuable cattle food Mr. Glendon Hill thinks this cake may in future b largely used for manufacture of artificial wool suc as 'Ardil'. The main ground-nut areas of East Afric are the western, central, lake and southern province of Tanganyika, the eastern province of Uganda, an the Nyanza and coast provinces of Kenya. Only small proportion of the crop is exported—21,000 ton in 1942. In 1936, 290,000 acres in Tanganyika an 167,000 acres in Uganda were under ground-nuts and in 1944 it was estimated there were 400,00 native growers in Tanganyika.

Types and varieties, soils and manures, cultivatio harvesting, diseases and pests, and crop economic are described. There are a great number of varietie which can be grouped into three main types, of whic the 'bunch' or 'upright' is the most desirable, a exemplified by Virginia Bunch, which is earl drought-resistant, gives good yield and oil conten but has hard shell. Spanish Bunch is even earlier, but with smaller yield. The ground-nut responds markedly to plant selection, which has been done in East Africa for some years with occasional notable success; for example, in evolving wilt-resistant strains. As it is not a self-fertile plant, selection and isolation of new strains is comparatively easy. Selection has been mostly directed to high yield and kernel percentage, with resistance to rosette disease; but not, so far as is known, to evenness in ripening—lack of which often causes serious trouble in harvesting—or to long dormancy and high oil content. In Uganda, bunch types are encouraged, but selection is proceeding with creeping types owing to their resistance to locusts. Selection has resulted in higher yielding varieties in some areas; but owing to the varying behaviour of different selections depending on season, final choice is difficult. In Nigeria, selection over five years resulted in 25 per cent yield increase in bunch type and 16 per cent in creeping type. Work with existing East African types is thought to be better than with imported varieties.

The best soils are light, sandy, well-drained loams, not too rich in organic matter; addition of lime and phosphate is often beneficial. The ground-nut fits in well with several different rotations, including cotton and maize. Fairly close spacing to keep the ground well covered is important, and weeds are often allowed to grow for this purpose. Yields per acre vary enormously according to conditions: from 200 to 2,200 lb. unshelled on native farms, though the average is nearer 600 lb., which is slightly less than the yield obtained in the United States. Mechanized farming in Queensland gives 3,600 lb. unshelled.

Sesame (simsim, ufuta, gingelly, bene, or til) has also high oil content, usually about 50 per cent, but sometimes much higher, with about 20 per cent protein and 18 per cent carbohydrate. Calcium content in the undecorticated product is remarkably high (1 per cent, mostly in the seed-coat), while phosphorus is 0·7 per cent. The main sesame areas in East Africa are: southern province of Tanganyika, northern province of Uganda, and Nyanza province of Kenya. It is mostly grown by native farmers for their own use, and the average yield is 350–400 lb. per acre. Care has to be taken not to contaminate with wild sesame (*S. radiatum* or *Ufuta mwitu*), which contains a substance toxic to cattle. There are many varieties, but the principal types are white and black. In Uganda, selection has aimed at high-yielding white-seed types for export, and has resulted in some improvement; as also in Tanganyika. Soils and climate, cultivation, harvesting, storage, pests, etc., are described. From the economic point of view, the yield from sesame is only about one third that of ground-nuts, and it is a major crop only where soils are sticky and make ground-nut harvesting expensive. It does not interest European farmers greatly.

Sunflower. As is well known, this crop covers vast areas in the U.S.S.R., and to a less degree in the Argentine, the Balkans, and China. It is not grown to any large extent in Africa. The best known in the past have been the giant types with heads 12–22 in. across, but easily sensitive obviously to wind and rain. A dwarf type has been introduced in Britain and elsewhere, such as the Pole Star, Southern Cross, Jupiter, and Mars. Attempts are being made to obtain seed of these varieties for trial in East Africa; but whether it is economically feasible there depends on world prices. Some notes on cultivation, etc., are given.

CHANK MARKING EXPERIMENTS AT TUTICORIN

FOR the purpose of ascertaining the migrations and growth-rate of the chank, marking experiments were begun in 1931 by the Madras Fisheries Department*. Since then about 5,000 chanks have been marked and liberated on the chank beds of Tuticorin. It was thought that there might be a migration of chanks from those beds to the Ceylon beds on the other side of the Gulf of Mannar. The experiments have shown that such migrations do not take place; but there are movements of chanks from one bed to another in the immediate vicinity. The greatest distance covered by any marked chank was nine miles.

There is marked variation in observed rates of growth, some specimens showing very little increase over long periods, while others have grown as much as 23 mm. in length in 23 months. The reason for this disparity is not known, but the suggestion is made that it may be due to variations in hydrological and other conditions on the different beds. This is a fairly safe guess, but it is no more than that. Much more work will have to be done and the data handled much more carefully and expertly before a sound knowledge of the bionomics of the chank can be acquired. It should not be necessary to state, for example, that of the 5,000 odd chanks that have been marked "only *about* 259 were recovered". Chanks are by no means minute animals, and the exact number recovered by the investigator must surely be known and should be recorded and reported upon with equal accuracy. In the absence of such accuracy little reliance can be placed upon any results obtained or conclusions reached.

Moreover, no scientific investigator should send out a paper in which only the local (common) name of the organism under investigation is given. Presumably the chank referred to in this paper is the gastropod *Turbinella pyrum*, Linn., but nowhere is this stated.

---

* Preliminary Study of the Chank Marking Experiments at Tuticorin. By K. Chidambaram and M. Mukandan Unny. A paper read before the Zoological Section of the Indian Science Congress, January 1947.

FORTHCOMING EVENTS

Monday, May 12

Farmers' Club (at the Royal Empire Society, Craven Street, Strand, London, W.C.2), at 2.30 p.m.—Mr. Martin Jones: "Ley Farming and the Livestock Population".

Institution of Post Office Electrical Engineers (at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W.C.2), at 5 p.m.—Mr. W. H. Leech: "The Work of the Sub-Marine Section during the War".

Society of Public Analysts and other Analytical Chemists, Biological Methods Group (in the West Hall, Royal Society of Medicine, 1 Wimpole Street, London, W.1), at 6 p.m.—Symposium on "The Production and Care of Laboratory Animals", Part 3. Dr. J. I. M. Jones and Dr. Eric C. Wood: "Housing"; General Discussion on all subjects.

Tuesday, May 13

Electrical Association for Women (at the Connaught Rooms, Great Queen Street, London, W.C.2), at 10.30 a.m.—Fourteenth Annual General Meeting.

Zoological Society of London (at Regent's Park, London, N.W.8.), at 5 p.m.—Scientific Meeting.

Institution of Electrical Engineers, Radio Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Discussion on "Future Trend of Component Design for the Services" (to be opened by Dr. G. W. Sutton and Mr. E. M. Lee).

Illuminating Engineering Society (at the Institution of Mechanical Engineers, Storey's Gate, St. James's Park, London, S.W.1), at 6 p.m.—Annual General Meeting; at 6.30 p.m.—Dr. N. A. Halbertsma: "International Relations in Illuminating Engineering".

Society of Instrument Technology, North-West Section (at the College of Technology, Manchester), at 7.15 p.m.—Annual General Meeting; Dr. J. Yule Bogue: "The Measurement of Non-Cyclical Biological Phenomena".

Wednesday, May 14

British Glaciological Society (in the Department of Geography, Downing Place, Cambridge), at 5 p.m.—Discussion on "Glaciological Research in the Antarctic".

Geological Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Scientific Papers.

Royal College of Surgeons (at Lincoln's Inn Fields, London, W.C.2), at 5 p.m.—Prof. F. Wood Jones, F.R.S.: "The Hallmarks of Humanity" (Arris and Gale Lecture).

Royal Meteorological Society (at 49 Cromwell Road, South Kensington, London, S.W.7), at 5 p.m.—Prof. C. Störmer: "Mother-of-Pearl Clouds".

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 5 p.m.—Mr. Alfred C. Bossom: "Economic Reconstruction, 8, Britain's Economic Future".

British Association for the Advancement of Science (at the Royal Institution, 21 Albemarle Street, London, W.1), at 5.30 p.m.—Prof. E. D. Adrian, O.M., F.R.S.: "The Sense of Smell" (Alexander Pedler Lecture).

Institution of Electrical Engineers, Transmission Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Dr. Waldemar Borgquist: "Recent Research and Development Work in Sweden on High-Voltage A.C. and D.C. Power-Transmission".

Royal Statistical Society, North-Eastern Group of the Industrial Applications Section (at the Newcastle Chemical Industries Club, 18 Lovain Place, Newcastle-upon-Tyne), at 6.30 p.m.—Mr. Glen Wortley: "The Use of Statistical Methods in Steel Production".

Wednesday, May 14—Friday, May 16

Iron and Steel Institute (at 4 Grosvenor Gardens, London, S.W.1).—Annual General Meeting.

Wednesday, May 14

At 10 a.m.—Symposium on "The Hardenability of Steel"; at 8.30 p.m. (at the Institution of Civil Engineers, Great George Street, London, S.W.1).—Dr. C. Sykes, F.R.S.: "Steels for Use at Elevated Temperatures" (Second Hatfield Memorial Lecture).

Thursday, May 15

At 9.55 a.m. (at the Institution of Civil Engineers).—General Meeting.

Friday, May 16

At 10.30 a.m. (at the Institution of Civil Engineers).—General Meeting.

Thursday, May 15

Institution of Mining and Metallurgy (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 4 p.m.—Annual General Meeting; Prof. W. R. Jones: "Geographic Changes in Mineral Producing Centres" (Presidential Address).

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Prof. P. M. S. Blackett, F.R.S.: "The Magnetic Field of Massive Rotating Bodies".

Chemical Society, Sheffield Section (joint meeting with the Sheffield University Chemical Society, in the Chemistry Lecture Theatre, The University, Sheffield), at 5.30 p.m.—Prof. J. B. Speakman: "Some Relationships between the Structure and Properties of Natural and Synthetic Fibres".

Royal Statistical Society, Tees-side Sub-group of the Industrial Applications Section (at the Cleveland Scientific and Technical Institute, Corporation Road, Middlesbrough), at 6.30 p.m.—Mr. W. L. Stevens and Mr. J. T. Richardson: "Statistical Control and Factory Costs".

Institution of Structural Engineers, Lancashire and Cheshire Branch (in the Reynolds Hall, College of Technology, Manchester), at 7 p.m.—Annual General Meeting.

Royal Society of Tropical Medicine and Hygiene (at Manson House, 26 Portland Place, London, W.1), at 8 p.m.—Discussion on "Amœbiasis" (to be opened by Dr. C. M. Wenyon, F.R.S.).

Friday, May 16

British Rheologists' Club (joint meeting with the Chemical Society, at the Washington Singer Laboratories, University College of the South-West, Exeter), at 2.15 p.m.—Discussion on "The Chemistry and Rheology of Clay Systems" (to be opened by Dr. G. Nagelschmidt and Mr. H. H. Macey).

Chemical Society, Manchester Section (joint meeting with the Local Sections of the Society of Chemical Industry and the Royal Institute of Chemistry, in the Chemistry Lecture Theatre, The University, Manchester), at 6 p.m.—Dr. G. M. Dyson: "A New Notation for Organic Chemistry".

Sheffield Metallurgical Association (joint meeting with the Royal Institute of Chemistry and the Microchemistry Group of the Society of Public Analysts, in the Chemistry Lecture Theatre, The University, Western Bank, Sheffield), at 6 p.m.—Scientific Papers.

Institution of Electronics, N.W. England Section (in the Reynolds Hall, College of Technology, Manchester), at 6.45 p.m.—Mr. A. Levins: "Radar Navigation".

Institute of Economic Engineering (at Cowdray Hall, 1a Henrietta Place, London, W.1), at 7 p.m.—Mr. A. W. Willsmore: "Practical Problems of Production Control".

Women's Engineering Society (at 35 Grosvenor Place, London, S.W.1), at 7 p.m.—"Women in Post-War Engineering".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Pasture Research Officer for Kenya—The Director of Recruitment (Colonial Service), Colonial Office, 15 Victoria Street, London, S.W.1 (May 17).

Lecturer in Neurology at Manchester Royal Infirmary—The Registrar, The University, Manchester 13 (May 19).

Lecturer in Chemistry and a Lecturer in Biology—The Clerk to the Governing Body, Battersea Polytechnic, London, S.W.11 (May 21).

Bacteriologist—The Secretary, Glasgow Royal Infirmary, 135 Buchanan Street, Glasgow, C.1 (May 22).

Assistant Lecturer (Grade III) in Mechanical Engineering, Assistant Lecturer (Grade III) in Civil Engineering, and Assistant Lecturer (Grade III) in Fluid Mechanics—The Registrar, The University, Liverpool (May 23).

Lecturer or Senior Lecturer in Electro-Technics—The Registrar, The University, Manchester 13 (May 24).

Senior Clinical Photographer—The Secretary and Registrar, The University, Bristol (May 24).

Lecturer in Civil Engineering—The Secretary, Queen's University, Belfast (May 24).

Assistant Keeper in Entomology in the Manchester Museum—The Registrar, The University, Manchester 13 (May 26).

Assistant Lecturer (Grade III) in the Department of Geology—The Registrar, The University, Liverpool (May 27).

Chief Photographer—The House Governor, King's College Hospital, Denmark Hill, London, S.E.5 (May 30).

Professional Officers in the Veterinary Branch of the Department of Agriculture and Lands, Southern Rhodesia—The Secretary, Office of the High Commissioner for Southern Rhodesia, 429 Strand, London, W.C.2 (May 31).

Analytical Chemist, and a Physical Chemist, in the Senior Scientific Officer grade in the Chemical Research Laboratory of the Department of Scientific and Industrial Research—The Secretary, Civil Service Commission, 6 Burlington Gardens, London, W.1, quoting No. 1866 (May 31).

Research Fellowship in Pure Science, and a Research Fellowship in Arts—The Secretary, University of Durham, 38 North Bailey, Durham (May 31).

Senior and Junior Research Fellowships—The Director, Atomic Energy Research Establishment, Harwell, Didcot, Berks. (May 31).

Lecturer in Civil Engineering, a Lecturer in Mechanical Engineering, and a Lecturer in Engineering Drawing and Design, in the University of Adelaide—The Secretary, Universities Bureau of the British Empire, 24 Gordon Square, London, W.C.1 (May 31).

Ramsay Memorial Fellowship for chemical research—The Joint Honorary Secretaries, Ramsay Memorial Fellowships Trust, University College, Gower Street, London, W.C.1 (May 31).

Reader in Pathology—The Secretary and Bursar, Royal Veterinary College and Hospital, Royal College Street, London, N.W.1 (May 31).

Curator and Deputy Curator for Horniman Museum, London Road, London, S.E.23, and a Curator for Geffrye Museum, Kingsland Road, London, E.2—The Education Officer (Estab. 2), County Hall, London, S.E.1 (May 31).

Lecturer in the Department of Bacteriology—The Registrar, The University, Liverpool (May 31).

Senior Entomologist and Assistant to carry out investigations into the control of midges in Scotland—The Secretary, Scientific Advisory Committee, Department of Health for Scotland, St. Andrew's House, Edinburgh 1 (May 31).

Chair of Physiological Chemistry, and an Assistantship in Electrical Engineering—The Secretary of the University Court, The University, Glasgow, W.2 (May 31).

Assistant Lecturer (Grade III) in the Department of Geography—The Secretary, University College, Gower Street, London, W.C.1 (May 31).

Lecturer and Chief Assistant in Public Health—The Registrar, The University, Leeds 2 (May 31).

Leverhulme Studentships in Chemical Engineering—The Secretary, University College, Gower Street, London, W.C.1 (June 1).

Coke Research Fellowship—The Registrar, The University, Sheffield (June 1).

Lecturer in Bacteriology in the Dental School—The Registrar, The University, Manchester 13 (June 2).

Assistant Lecturer in Physics, and an Assistant Lecturer in Mathematics—The Registrar, University College of South Wales, Cathays Park, Cardiff (June 8).

Assistant Civil Engineers for the Directorate General of Works—Under-Secretary of State (S.2(h)), Air Ministry, Cornwall House, Stamford Street, London, S.E.1.

Engineer (British) in the Recording Section of the Research Department of the B.B.C.—Engineering Establishment Officer, Broadcasting House, London, W.1.

Senior Assistant in the Department of Metallurgy—The Principal, Central Technical College, Suffolk Street, Birmingham 1.

Senior Laboratory Steward in the Chemistry and Biology Department—The Registrar, Municipal College, Portsmouth.

Senior Technician in the Department of Anatomy—The Secretary, St. Mary's Hospital Medical School, London, W.2.

Senior Technician in the Pathological and Bacteriological Laboratory—The Medical Superintendent, Dudley Road Hospital, Birmingham 18.

Physical Chemist to conduct research on corrosion problems—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W.1, quoting 'Chemistry Department'.

Research Manager, and Chemists and Physicists on the research staff—The Director, Paint Research Station, Waldegrave Road, Teddington, Middx.

TECHNICAL COLLEGES AND INDUSTRIAL RESEARCH

IN his paper "Industrial Research and the National Economy" at the Midland Regional Conference of the Federation of British Industries on March 25, Sir William Larke stressed the important part which the technical colleges of Great Britain should play in the conduct of technical research. Mr. F. E. W. King, in a review of the Midland research organisations at the same Conference, commented on the comparative neglect of research by the technical colleges in the past, and suggested that the implementation of the recommendations of the Percy Report on Higher Technological Education should do much to remedy this position. More recently, at the Scottish Regional Conference of the Federation of British Industries, on April 25, Dr. W. M. Cummings also referred to the assistance which the technical colleges could give to industry, both in the way of technical research and in consulting work.

Dr. Cummings went on to urge the need for closer contact and better mutual understanding between the technical colleges and industry in Britain, and although his remarks related more particularly to chemical industry in Scotland, it is clear from the report on "Industrial Research in Technical Colleges", to which Sir William Larke referred in his paper at Birmingham, that much of what Dr. Cummings said is true of all subjects and throughout Great Britain. This report, by a special sub-committee of the Industrial Research Sub-Committee of the Federation of British Industries which was appointed "to consider the results of a survey on the industrial research activities of Britain's technical colleges and the Ministry of Education's future plans for industrial research in technical colleges; to report on the possibility of co-operation by industry and the form such co-operation might take", shows that, of the fifty-seven technical colleges selected from approximately two hundred by the Ministry as likely to provide positive answers, thirteen were not carrying out research, twenty-nine, including the majority of the senior technical colleges, were carrying out some research, and in only fifteen colleges were more than five persons engaged in research. About ten of the colleges possess special equipment of value for industrial purposes; all have close links with industry, and all but two possess satisfactory libraries. About 250 research workers, of whom about 160 are staff, were reported in the returns in this category, as against 72, of whom 52 are staff, in the returns from the twenty-five colleges in the second category.

The overall picture gained from the survey of the most active colleges is one of progressive development, handicapped by inadequate facilities and equipment, and by lack of staff. Moreover, in only seven of the fifty-seven colleges questioned do research scholarships exist, although there are grants from the Department of Scientific and Industrial Research to individual investigators and a few endowments from industry. Again, where there is close contact with local industry, it is normally through heads of departments, who act from time to time in a consultant capacity. Frequently, testing for local industry is carried out by technical colleges, often with specialized equipment for the purpose. Development work in assisting in the application of the results of research is limited mainly to the special war-time requirements of local firms, and contacts with the research associations and the Department of Scientific and Industrial Research are limited and spasmodic.

Commenting on the position revealed by the survey, the Sub-Committee, which consisted of Sir Robert Pickard (chairman), Dr. W. T. K. Braunholtz, Sir Arthur Fleming, Mr. Edward Meigl and Dr. B. J. A. Bard as secretary, considers that the amount of research carried out, and the extent to which the technical colleges are assisting local industry in the way of research, development or advice, are inadequate when measured either in terms of the resources and potentialities of technical colleges or the requirements of industry. Moreover, it holds that industry is not, and has not been, made sufficiently aware of the facilities that exist in technical colleges, or the assistance they can provide in the solution of industrial problems and in the application of scientific knowledge for the benefit of local industry. More particularly, since the imparting of knowledge cannot be separated from its advancement, if teachers are to maintain their enthusiasm, and the right type is to be attracted to the profession, the Committee urges that opportunity for research by the teaching staff should be a *sine qua non* in all senior technical colleges, and that opportunity should simultaneously be provided for graduates and students to participate in original investigations related to local needs and interests.

On the scope of such research the Committee recognizes that the primary responsibility of the technical college is to train men for technical positions in industry, and that accordingly any research prosecuted should bear some relation to this objective. The training of men for research posts in industry, however, is not necessarily outside the function of the technical college; and on the other hand, carrying out industrial investigations may assist members of the staff of the technical college to keep up to date in their knowledge of industrial practice and thus relate their teaching more closely to industrial needs. So far as long-range fundamental research is concerned, the Committee believes that such research is best carried out at a university or independent institution, or by an industrial research association; although on occasion such investigations may be suitable for technical colleges if they are adequately staffed and equipped.

As to actual research for local industry, the Committee endorses the views expressed by the Ministry of Education last year in Circular 94; but it suggests that investigations of which a manufacturing concern offers to bear the full cost, with a proviso prohibiting or restricting publication of results, should be considered with regard to the possible benefit to the college. Similarly, in regard to consultation with local industry, the Committee endorses the principles laid down in the statement "Principles suggested for a Code of Practice in respect of consulting and similar work accepted by members of whole-time academic staff" which was approved and issued last year by the Board of the Institute of Physics and the Council of the Royal Institute of Chemistry.

The Committee believes that the plans for encouraging research in the technical colleges outlined in the Ministry of Education's Circular lay a sound foundation, and most of the colleges have plans in hand for expanding their research effort. It is, nevertheless, considered that industry can contribute to the success of research work at technical colleges, and that this in turn will benefit industry itself. Industry should take increasing interest in the technical college, not only as a place where staff can be trained, but also as a centre which may be of supplementary assistance to the research activities of the industry and the private consultant in the solution of both general and particular industrial problems. Accordingly, the report recommends that industrial concerns with their own research departments should, wherever possible, place research work with their local technical college, and consult the college when an outside opinion or specialized advice within its competence is required. They should also provide financial help and equipment where required, to increase the capacity for service to industry, arrange for interchange of staff, for vacation and refresher courses and works visits from time to time, encourage the organisation by the college of a reference library and information service related to its field of activity, and generally develop the closest possible relations for their mutual benefit, including active participation on the governing body.

Each trade association should ascertain which technical colleges in Great Britain can be of assistance to the industries it represents, and should assist financially in the provision of equipment or personnel where necessary, as well as maintain contact with regional education councils and local education authorities.

The Industrial Research Secretariat of the Federation of British Industries, the Committee suggests may well play a constructive part in bringing industry and technical colleges into closer contact for the solution of industrial problems; and the two regional conferences which the Federation has organised since this report was signed are steps in the right direction. The Secretariat can act to some extent as a clearing house, though the Intelligence Division of the Department of Scientific and Industrial Research should be equally effective, and care should be taken to avoid overlapping and duplication of effort. The Federation's Industrial Research Secretariat would rightly welcome any approach from a technical college to obtain information or make research or industrial contacts, or with regard to the initiation of staff exchange schemes; indeed, there should be a wide field in which there is little risk of duplicated effort. Moreover, the appendix (dated January 1, 1947) listing technical colleges with research activities and facilities likely to interest industry indicates that in the way of information much co-operative effort is still required to fill the gaps in systematic knowledge.

The information in this list was supplied by the Association of Principals of Technical Institutions. It is somewhat fuller than that contained in the lists of industrial research in technical colleges and at the universities appended to Mr. J. G. King's paper on Midland research organisations read at the Midland Regional Conference of the Federation last March, which was derived mainly from the Federation's own records or from the "Notes on Current Scientific Researches in the United Kingdom" prepared for the Royal Society Empire Scientific Conference last year; but neither list is complete, and the approval with which the "Notes" were received at the Empire Scientific Conference shows how warmly such an authoritative and comprehensive compilation would be welcomed. Naturally it could never be entirely up to date, but if maintained by the appropriate bureau it should do much to assist contact between industry and the technical colleges and also the universities, and especially to help the technical colleges to plan their own research.

The report of the Federation of British Industries Sub-Committee is chiefly of value as indicating the approval by an important section of industry of certain current trends of opinion in educational and professional opinion, as reflected, for example, in the Ministry of Education Circular and in the Code of Practice issued by the Joint Council of Professional Scientists; but beyond showing that the Federation is aware of the possibilities of the educational work it could undertake in promoting contact between the technical colleges and individual firms, and that it is prepared to use those opportunities to the full, the report contains little in the way of constructive proposals. Moreover, there are some important omissions. There is no reference to recent developments, such as refresher courses, which can indeed prove as valuable to the teacher in the technical college as to the staff of an industrial firm. The Joint Research Council established in Manchester, too, may well become, as Dr. W. H. Cummings suggested at Glasgow, the prototype of what is required in other regions to facilitate contacts between both technical colleges and the universities and local industry.

On the proposals of the Percy Report on Higher Technological Education the Committee makes no comment, and its survey of the relations between technical colleges and the universities, seems to be somewhat superficial. The Percy Committee missed an opportunity when it concerned itself exclusively with the needs of engineering and failed to compare the needs and experience, for example, of the engineering and chemical industries, and the present report takes rather too narrow a view of the training of the staff in the technical colleges. The only really satisfactory way for such teachers to keep up to date in the industrial technique of their particular subject is for the teacher to return to industry for substantial periods. The conduct of subsidized *ad hoc* investigations for industrial firms in the laboratories of a technical college is unlikely of itself to meet that need, yet the report gives no indication of the views of the Committee as to how such interchange should be encouraged. Satisfactory as the report may be so far as it goes, and rightly as it emphasizes the opportunities for research which the technical colleges could offer, on the whole the Committee has approached the subject too timidly, and has failed to define sufficiently clearly the relative functions of the universities and technical colleges; it has overlooked the importance of free interchange between the technical colleges and the universities, and between both these and industry, and has confined itself to the general point that research could be carried out more extensively at the technical colleges, without indicating the character of the investigations which it is reasonable to expect the technical colleges to be equipped to pursue. There is little attempt to define clearly the conditions on either side for closer co-operation. By contrast, Prof. Edmund Giffen's inaugural lecture at Queen Mary College, London, on "Engineering Research in the University" (Oxford University Press, London, 1946. 1*s.* 6*d.* net) is marked by clear thinking on fundamental aspects. One would have welcomed comments from the Federation of British Industries' Sub-Committee on Prof. Giffen's suggestions, and more particularly on the scheme he proposes for co-operation between the universities and research associations. Such a scheme should be equally applicable to the technical colleges and to fields other than that of engineering; but the inherent weakness of the research association movement itself renders further industrial contact essential if the technical college is to reap the full benefit of intimate contact with the most recent advances in industrial practice and technique. Here the joint research council on the lines of that at Manchester might contribute something, and it is to be hoped that the promised report from the Parliamentary and Scientific Committee on schools and colleges of technology in Great Britain in relation to scientific and technical man-power will take the matter a stage further, and deal more imaginatively and constructively with these important questions.

NEW LIGHT ON VESALIUS

A Prelude to Modern Science

Being a Discussion of the History, Sources and Circumstances of the "Tabulae Anatomicae Sex" of Vesalius. By Charles Singer and C. Rabin. (Publications of the Wellcome Historical Medical Museum, New Series, No. 1.) Pp. lxxxvi+58+6 plates. (Cambridge: At the University Press, 1946.) 45*s.* net.

DR CHARLES SINGER has celebrated his seventieth birthday by the publication of one of his most important contributions to the history of science. The works of Vesalius have attracted more attention, and have been more intensively scrutinized, than those of any other anatomist, and it might well be thought that there was nothing more to be said. It is true that we still await an English translation of the "Fabrica", but even this monumental and baffling task is approaching completion in the United States. Now Dr. Singer has raised Vesalian commentary to so erudite a plane that his successors must perforce master the technique of the higher criticism if their labours are to command attention and respect.

In this work Dr. Singer has secured the collaboration of Dr. C. Rabin—a name new to students of the history of science. He is assistant to the professor of Arabic in the University of Oxford, specializing in comparative Semitic philology, and the contribution to the volume of such a scholar obviously adds much to its content and importance. Dr. Singer himself, however, has devoted many years to the study of Latin anatomical and medical terms which had a Semitic origin. The plan of this "Prelude to Modern Science" includes the following sections: (1) character and purpose of the "Tabulae Sex", printed in 1538; (2) Vesalius and the schools of Louvain and Paris; (3) Italian predecessors of Vesalius; (4) Galenic physiology and its Latin presentation; (5) certain anatomical elements of the Tabulae (for example, reliance of Vesalius on animal anatomy, rete mirabile, etc.); (6) Renaissance anatomical vocabulary; (7) Semitic elements in the Tabulae; (8) translation of and commentary on the Tabulae; (9–12) general, Greek, Arabic and Hebrew indexes and reduced facsimiles of the six plates of the Tabulae.

The authors regard the "Fabrica" of Vesalius, published in 1543, as "the first great achievement of modern observational science. It opens a new scene as with the quick rise of a curtain, for it is suddenly, essentially and brilliantly modern—modern in appearance, modern in outlook, modern in method, modern in its art and in its technique. And modern, too, in what it omits no less than what it includes. It is a startling apparition in the very midst of that imitative world of the revival of classical learning which still pervades its language." Yet the Tabulae Sex, printed only some five years earlier, is quite different in outlook, and is inspired by Galen and medieval tradition even to the extent of grafting the rete mirabile of an ungulate on to the arterial system of man. The explanation of this contrast constitutes a 'Vesalian problem', of which the authors produce a convincing solution. They point out that by the sixteenth century medicine was deeply committed to the acceptance of hypothetical entities "the separate existence of which no one could verify and, therefore, no one would deny". It had become, indeed, highly astrological. A very young man such as Vesalius was at the time could scarcely fail in his early work to be influenced by current obsessions; but his reaction to the call of factual anatomy, as embodied in the later "Fabrica", "gave in a trice a new and far more positive basis to medical thought. In the course of a very few years medicine was to become anatomical. Observational science was thus born with the shortest of birth pains."

One of Vesalius' most inspiring successes was his exploitation of the graphic method of teaching anatomy, and if he did not initiate this method he was the first to demonstrate that it was an indispensable adjunct to the study of animal structure. It is generally accepted that the figures in the "Fabrica" were the work of Calcar, a pupil of Titian. The present authors agree that the three skeletons of the Tabulae "are certainly by Calcar", but that they compare so unfavourably with the corresponding figures of the "Fabrica" that it is "unlikely" that Calcar played more than a minor part in the illustration of that work. "With these plates [of the Tabulae] Calcar effectively disappears from the anatomic scene, nor does he, in doing so, shroud himself in a cloud of glory." It is suggested that the artist of the "Fabrica" "was a young man, unknown to fame, who died before the book was printed".

The authors give us a detailed and enlightening picture of the early days of Vesalius and of the forces which moulded him during his stay in Belgium, France and Italy. Thus in the thirties his early researches had as their driving motive the verification of Galen; but in the forties he had realized that his Paris masters, Guenther and Sylvius, "were almost indifferent to dissection and were enthusiasts only for what Galen had written". Therefore, to achieve his purpose he must put his own hand to the business. Nevertheless, as the authors point out, the break with Galen took longer than he would have us believe, and it is only in the "Fabrica" that he is revealed as a discoverer, and as a "modern man of science with a rovingly enquiring mind and the habit of presenting his own findings in pictorial form". In this connexion an examination of Galenic physiology is called for and given, and we have an admirably clear and informative statement of Galen's views on the movements of the blood, illustrated by a useful diagram.

The failure of Vesalius to admit that his descriptions are often based on animal and not on human anatomy has been revealed by a number of authors, but never so critically as in the present work. It is an almost inexhaustible topic of discussion, and the authors attack it in no carping spirit, but with a sympathetic understanding of the difficulties of the period. They point out that, but for the unfortunate element of deception involved, the animal approach to human anatomy should be counted for righteousness in those who practised it, and that when the Padua professors abandoned the comparative method the greatness of their school faded with it. They admit that Vesalius must certainly have dissected far more animals than men, but add that certain anatomical features are more profitably investigated in animal bodies than in human. Many structural details were examined at first hand by Dr. Singer himself in his critical and fascinating attempt to determine how much of the "Tabulae" and "Fabrica" is to be assigned to animal, and how much to human, anatomy. More remains to be done under this head, and Dr. Singer's results are too striking to remain without companions. The following are the main points so far elucidated: rete mirabile; position and form of the heart; branches of the aortic arch; the caval systems; posterior intercostal vessels; relative levels of kidneys and renal vessels; lobes of the liver; genital organs of both sexes; prostate gland; asymmetry of spermatic veins; segments of sternum.

The introductory matter concludes with a scholarly essay of twenty-one pages by both authors on the anatomical vocabulary of the Renaissance and the Semitic elements in the "Tabulae". The modern history of anatomical terminology may be said to have begun in three works by Joseph Hyrtl, published in 1879, 1880 and 1884, of which the second is the most important. All, however, now need revision, and the present essay points to its authors as the source from which this comprehensive revision should come. They have already done much, but as the "Tabulae" do not include the viscera the entire field has yet to be covered before a substantial vocabulary of medieval anatomy can be attempted. In the meantime, the general index of the present work, combined with the text, provides us with an analysis of medieval Latin medical and anatomical terms, many of which are still employed, of the greatest value and interest.

Probably most students who are not masters of Eastern languages will value particularly Part 8 of the work, which is an English translation of the "Tabulae Sex", accompanied by 343 exhaustive annotations, and photographic reproductions of the six plates and Latin text. Of the "Tabulae" two complete sets of the original issue are all that have survived, but there are three facsimile editions, only one of which, however, is readily procurable. Now all interested can possess this excellent facsimile copy, which for the purposes of research is as good as the original, and for which we must express our thanks to the authors and also to the Wellcome Historical Medical Museum for undertaking the responsibility of production.

The book has been admirably printed and bound, but exception must be taken to the abominable backing of the six plates. The general editor of the series, Dr. E. Ashworth Underwood, informs us that this was the only material at the printer's disposal, and it was therefore either that or nothing.

Drs. Singer and Rabin are to be warmly congratulated on an addition to Vesalian literature which will surely rank as a classic in times to come.

F. J. COLE

PHYSIOLOGICAL EMBRYOLOGY

Einführung in die Physiologische Embryologie
Von Prof. F. E. Lehmann. (Lehrbücher und Monographien aus dem Gebiete der exakten Wissenschaften, 5.) Pp. 414. (Basel: Verlag Birkhäuser, 1945.) 38 Swiss francs.

THE years between the two World Wars saw a very rapid accumulation of experimental data bearing on the mechanism of development in many groups of animals, particularly the echinoderms and the vertebrates. By the end of the 1930's, most experimental embryologists felt the need for a synthesis, and the elaboration of a theoretical structure by which the facts could be held together in an illuminating way. The disturbances of the War necessitated a slackening in the pace of experimental work, and the leaders of most of the major schools of experimental embryology took the opportunity to try their hand at producing the necessary system of thought. Spemann, whose work provided the original inspiration for much of the recent progress, led off with his "Experimentelle Beiträge zu einer Theorie der Entwicklung" in 1936; then from America we were offered Weiss' "Principles of Development" in 1939, and Child's "Patterns and Problems of Development" in 1941; from Britain, Waddington's "Organisers and Genes" in 1940 and Needham's monumental "Biochemistry and Morphogenesis" in 1942; from Belgium, Dalcq's "L'œuf et son Dynamisme Organisateur" in 1941 and Brachet's stimulating "Embryologie Chimique" in 1944. We are still waiting, not too patiently, for a similar thorough treatment from the point of view of the Swedish school of Runnström and Hörstadius.

It is in the setting of this series of works that Lehmann's "Einführung in der Physiologische Embryologie" will be studied. Prof. Lehmann is known as one of the earlier of Spemann's pupils, and for the last twenty years a steady stream of interesting and very thorough papers have issued from his laboratory in Switzerland, mostly devoted to the analysis of organiser action in the Amphibia. Two thirds of his book are devoted to this group of animals. In the remaining third he discusses the recent work, mainly Swedish, on the echinoderms. This restriction of his field enables Prof. Lehmann to describe the experimental data in considerably greater detail than was possible in most of the books mentioned above, and his work thus provides a summary of facts which will be very useful to the student.

In other respects the results of this policy of exclusion are not so happy. Although the two groups chosen by Lehmann are undoubtedly those in which our knowledge is fullest, yet there are many suggestions of considerable importance to be derived from studies on other animals. Moreover, the epigenetic system of the echinoderm egg is so different from that of the amphibian that a mere discussion first of one and then of the other produces rather two separate monographs than one unified book. The two systems can scarcely be brought into fruitful relation without some account of the spiral-cleaving invertebrates and the Prochordates; while the most direct illumination of the difficult problems in amphibian embryology must be derived from the birds and fish rather than from a group so far removed as the sea-urchins.

Our understanding of the epigenetic processes by which the organism is formed is still at a fairly early stage. The end-results are living animals, organs and tissues. These cannot yet be fully comprehended in physical or chemical terms; and it is thus impossible that a purely physico-chemical theory of development could be adequate. Nevertheless, the theoreticians of experimental embryology are presented with a choice—they may choose to emphasize the more specifically 'biological' aspects of their subject-matter, or they may decide to try to formulate concepts which, as it were, lead towards the realm of physico-chemical ideas. Much of the recent work has been inspired by the second tendency. Although Prof. Lehmann faithfully summarizes this, and indeed speaks highly of its value, his most characteristic ideas seem to belong rather to the former trend. This impression may be partly due to the arrangement of his matter, which he divides into the purely descriptive, the 'entwicklungsmechanisches', and the physiological, a scheme which means that the treatment of each question, instead of proceeding steadily from the biological towards the physico-chemical, is broken into separate parts located in different chapters. This dislocation tends to diminish the field to which the more physico-chemical ideas are applied. Similarly, Lehmann relies to some extent, as any author dealing with this material must do, on such essentially unclear notions as 'fields', gradients, and so on. But he sets this aspect of his theories in the centre of the stage, and goes out of his way to emphasize its organismic character by the frequent use of long German phrases full of overtones —"plastisches Blastemfeld" instead of plain 'field', "Organisatorblastem" for organiser, and such expressions as "topogenetischen begrenzte Selbstorganisation", "kombinative Einheitsleistung", and so on. This type of approach is one which does not appeal to the reviewer as much as does that of some of the other recent works; but it represents a necessary corrective to any possible over-confidence in the complete adequacy of biochemical embryology in its present state.

C. H. WADDINGTON

THE MAGNETIC FIELD OF MASSIVE ROTATING BODIES*

By PROF. P. M. S. BLACKETT, F.R.S.
The University, Manchester

Summary

IT has been known for a long time, particularly from the work of Schuster, Sutherland and H. A. Wilson, though lately little regarded, that the magnetic moment P and the angular momentum U of the earth and sun are nearly proportional, and that the constant of proportionality is nearly the square root of the gravitational constant G divided by the velocity of light c. We can write, in fact,

$$P = \beta \frac{G^{1/2}}{c} U,$$

where β is a constant of the order of unity.

For the first time, the magnetic field of a star, 78 Virginis, has recently been measured (Babcock, 1947). Using the best estimate available for its mass, radius and rotational velocity, the calculated value of the magnetic field agrees with its observed value. We have, therefore, a rough verification of the equation above for three bodies, the earth, sun and 78 Virginis, and covering a range of P and U of more than $10^{10}:1$, though only of 2,000 : 1 in measured field. It is therefore considered that the above equation must be taken seriously as a possible general law of Nature for all massive rotating bodies.

If white dwarfs are collapsed forms of stars like the sun, then they should have the same angular momentum and so, according to the equation above, the same magnetic moment. Owing to their small size, they will have a surface magnetic field of the order of 10^6 gauss. It is suggested that magnetic fields of this order may be in part the cause of the large breadth of the Balmer lines in many white dwarfs, and of the complete absence of any lines in some very dense ones. The various alternative theories of the magnetic field of the earth and sun are discussed. It is suggested tentatively that the balance of evidence is that the above equation represents some new and fundamental property of rotating matter. Perhaps this relation will provide the long-sought connexion between electromagnetic and gravitational phenomena.

1. The Magnetic Field of the Earth, the Sun and a Star

While considering the possible influence of the magnetic fields of stars in the galaxy on cosmic ray phenomena, I noticed two results which seemed to me of great physical interest. The magnetic moments P of the earth and the sun are nearly proportional to their angular momenta U, calculated from the expression

$$U = \frac{2}{5} \omega M R^2 \quad . \quad . \quad . \quad (1)$$

for a uniformly dense sphere of mass M, radius R and angular velocity ω. This proportionality can be seen from the figures in Table 1.

TABLE 1

Body	Mass M (gm.)	Radius R (cm.)	Angular velocity ω (sec.$^{-1}$)	U	H_P (gauss)	P	P/U
Earth	$6{\cdot}0 \times 10^{27}$	$6{\cdot}37 \times 10^8$	$7{\cdot}3 \times 10^{-5}$	$7{\cdot}1 \times 10^{40}$	0·61	$7{\cdot}9 \times 10^{25}$	$1{\cdot}11 \times 10^{-15}$
Sun	$2{\cdot}0 \times 10^{33}$	$6{\cdot}97 \times 10^{10}$	$2{\cdot}9 \times 10^{-6}$	$1{\cdot}12 \times 10^{49}$	53	$8{\cdot}9 \times 10^{33}$	$0{\cdot}79 \times 10^{-15}$

Measured values of the polar magnetic fields are also given. These are related to the magnetic moments by the expression

$$H_P = 2P/R^3. \quad . \quad . \quad . \quad . \quad (2)$$

It has long been known that the directions of rotation and of the magnetic moments of the two bodies are similarly related; in fact, in both bodies, the south magnetic poles are near the north geographical poles.

It was natural to compare the mean ratio $(P/U)_1$ of the magnetic moment to angular momentum of these two astronomical bodies with the similar ratio

$$(P/U)_2 = e/2mc = 0{\cdot}88 \times 10^7 \text{ cm.}^{1/2} \text{ gm.}^{-1/2} \quad (3)$$

for a Bohr magneton. We have

$$(P/U)_1/(P/U)_2 = 1{\cdot}08 \times 10^{-22}, \quad . \quad . \quad (4)$$

and one recognizes immediately that this numerical value is close to that of the well-known non-dimensional ratio

$$G^{1/2}\, m/e = 4{\cdot}90 \times 10^{-22} \quad . \quad . \quad (5)$$

of the gravitational mass of an electron to its charge in E.S.U. We can thus write

$$(P/U)_1 = \beta \frac{G^{1/2}\, m}{e} (P/U)_2, \quad . \quad . \quad (6)$$

where β is a small numerical constant of magnitude about 1/4; whence with (3) we find for the relation between the magnetic moment and angular momentum of both astronomical bodies

$$P = \beta \frac{G^{1/2}}{2c} U. \quad . \quad . \quad . \quad (7)$$

The simplicity of this result, either in the form (6) or (7), suggested that it must have some profound physical significance.

Stimulated thus to study the voluminous literature concerning the origin of the magnetic fields of the earth and sun, I found to my surprise that the essence of these facts had been known for many years, but had, for various reasons, dropped lately out of notice. A survey of this earlier work will be given in the next section.

Seeking a further test of equation (7), I thought at once of the possibility that the magnetic field of some rapidly rotating star might be measurable. I am indebted to Prof. S. Chandrasekhar for giving me early news of the first measurement of the magnetic field of a star that has ever been made. The measurements by Babcock[1] on 78 Virginis have now been published and give a polar field of 1,500 gauss. To calculate P and U we require its mass, radius and angular velocity. From statistical evidence on stars of similar type, the probable values of these quantities in terms of the values for the sun are found to be $M = 2{\cdot}3$, $R = 2{\cdot}0$, $\omega = 25$ (see Section 4). Table 2 gives the resulting data for the star.

TABLE 2

Body	M	R	ω	U	H	P	P/U
78 Virginis	$4{\cdot}6 \times 10^{33}$	$1{\cdot}4 \times 10^{11}$	$7{\cdot}3 \times 10^{-5}$	$2{\cdot}6 \times 10^{51}$	1500	$2{\cdot}1 \times 10^{36}$	$0{\cdot}81 \times 10^{-15}$

We find again about the same ratio for P/U, showing that (7) holds not only for the earth and sun but also for 78 Virginis. The relation between the directions of the rotation and the magnetic field is not known. This further support for the validity of (7) suggests, on one hand, that it must be taken seriously as a possible new general law of Nature, and on the other, that a more rigorous test of its validity must be made, taking into account the variation of density and possibly also of rotation inside the bodies.

---

* Paper presented before the Royal Society of London on May 15.

2. Previous Theories of the Magnetic Field of the Earth and Sun

Though the main dipole field of the earth is known to be of internal origin, how it is produced is still obscure. A critical discussion of the extensive literature is given by Chapman and Bartels[2] (1940). The earlier surveys by Schuster[3] (1912), Brunt[4] (1913) and Swann[5] (1923) are still of great value. Possible theories of the sun's field are discussed in a recent paper by Cowling[6] (1945).

Theories of the main field of the earth or sun may conveniently be divided into two classes, which may be called *specific* and *general* theories.

A *specific* theory is one which attributes the magnetic properties of a rotating body to the specific properties of the matter of which it is composed; in such a theory the magnetic moment of a massive body would depend on the specific electrical, magnetic, thermal and mechanical properties of its material, and so is likely to have quite different values for bodies in different physical conditions.

The first theory of this kind, that the earth is ferromagnetic, has long been abandoned, since the internal temperature of the earth is almost certainly well above the Curie points of any materials likely to be present. The obvious alternative is to assume the existence of an electrical conduction current in the earth. The difficulty is to find a mechanism which will maintain it. To explain the sign of the field, a positive current must flow from east to west or a negative one from west to east.

A recent attempt by Elsasser[7] (1939) attributes the current to thermo-electric E.M.F.'s arising from temperature differences in the fluid core due to convective motions. The essential asymmetry required to produce a net circulation around the axis is attributed to the action of Coriolis forces on the convecting masses. In a subsequent paper Elsasser[8] (1941) discusses the relation between the main large dipole field of the earth and the irregular part which amounts to a few per cent of the main field. The origin of both is held to be in the central core of molten metal of radius about 0·55 *R*.

A rather similar theory by Frenkel[9] (1945) introduces in addition a self-excitation mechanism, such as had been considered by Gurevich and Lebedinsky[10] (1945) to be the origin of the magnetic field of sunspots. The first theory involving a self-excitation or dynamo mechanism was put forward by Larmor[11] (1919) and was elaborated in detail by Cowling[12] (1933) and shown to fail to explain either the magnetic field of sunspots or the main fields of the earth and sun. Cowling[6] (1945) showed, too, that thermal effects due to convection in the rotating sun give the right sign but in magnitude only 10^{-7} of the observed field. He also shows that the time of electromagnetic decay of the sun's general magnetic field is 10^{10} years, so that the field might be a relic from a different primeval state. But Lamb (for example, see Chapman and Bartel, ref. 2, vol. 2, p. 704) had shown long ago that the decay of currents in the earth would be far too quick to allow the field to be explained as a survival.

A *general* theory is one that attributes the dipole field to some general property of rotating matter. Already in 1891, Schuster[13], suspecting from the appearance of the solar corona that the sun might have a magnetic field, had put the question, "Is every large rotating mass a magnet ?"

The only obvious atomic effect of a general character is that of magnetization by rotation, that is, the gyro-magnetic effect. This gives the right sign, but a moment 10^{10} too small (ref. 2, p. 705). But, as Schuster showed[3], any such uniform magnetization gives a total moment proportional to the volume of the sphere and so a surface field which is independent of the radius. Thus any such theory can be excluded.

In a series of papers, Sutherland[14] (1900–8) assumed that the earth's magnetic field is due to its possession of a positive volume charge compensated by a negative surface charge. He calculated the charge density required and showed that it implies electric fields inside the earth of the order of 10^8 volts per cm. He also noticed that the separation of charges, as calculated from the observed magnetic field of the earth, had about the same magnitude as would occur if gravitation were explained, on the basis of Lorentz's pre-relativity theory (for example, ref. 3), as due to a slight difference between the electric forces between two protons, two electrons, and an electron and a proton. This is, in essence, an early recognition of the numerical result explicitly stated later by Wilson[15] (1923), which expresses in a rather different way the result already given in section 1.

In 1912, Schuster gave a survey[3] of the possible theories and their difficulties, and studied in some detail one similar to that of Sutherland, depending on the assumption of unequal forces between like and unlike atomic particles. Brunt[4] (1913) surveyed many different theories and also showed that the separation of positive and negative charges in the sun's gravitational field could not produce more than 10^{-15} of the sun's magnetic field.

H. A. Wilson[15] (1923), following a suggestion of Schuster[3], showed that one obtained the right order of magnitude for the fields of the earth and sun if one assumed that a moving mass element *M*, measured in gravitational units, has the same magnetic effect as a moving negative charge *Q* measured in E.S.U. The measure *M* of the mass of a body in gravitational units is defined by the equation $F = M_1M_2/r^2$ for the gravitational force between two masses. Comparing this with the expression $F = Gm_1m_2/r^2$, where m_1 and m_2 are measured in grams, we have $M = G^{1/2}m$, whence the gravitational unit of matter amounts to $G^{-1/2} = 3,870$ gm.

Wilson's hypothesis, expressed formally, amounted to the assumption that a mass element *m* gm., or *M* gravitational units, when moving with velocity *v* gives, at a distance *r*, a magnetic field,

$$H = -\frac{M}{cr^3}[v.r] = -\frac{G^{1/2}m}{cr^3}[v.r] \quad . \quad . \quad (8)$$

in analogy to the non-relativistic expression for the magnetic field of a moving charge *Q* E.S.U., which is:

$$H = \frac{Q}{cr^3}[v.r]. \quad . \quad . \quad . \quad . \quad (9)$$

From (8), we find by integration that the magnetic moment *P* of a sphere of mass *M* and uniform density ρ, radius *R* and angular velocity ω, is given by

$$P = \frac{1}{5}\frac{G^{1/2}}{c}\omega MR^2. \quad . \quad . \quad (10)$$

We note that (1) and (10) together give (7), apart from the constant β. The surface magnetic field at the pole is, from (2),

$$H_P = \frac{2}{5}\frac{G^{1/2}}{c}\frac{\omega M}{R}, \quad . \quad . \quad . \quad (11)$$

or expressed in terms of the density ρ

$$H_P = \frac{8}{15}\pi\frac{G^{1/2}}{c}\omega\rho R^2. \quad . \quad . \quad . \quad (11a)$$

Wilson showed that (11) gave the right ratio for the field of the sun and the earth, but numerical values about three times too great.

An alternative way of expressing this result is that the earth's magnetic field is such that would be produced if it possessed a volume negative charge density σ, given in terms of the mass density ρ by

$$\sigma \cong G^{1/2}\rho. \quad . \quad . \quad . \quad (12)$$

Angenheister[16] (1925) also stressed the fact that the assumption of an electric charge density proportional to the mass density gives nearly the correct ratio for the magnetic field of sun and earth. He clearly recognized the physical difficulties of assuming the existence of *real* charges of such a magnitude, and of the large electric fields which must accompany them, in an electrically conducting material such as the earth's core.

Wilson[15] (1923) made a laboratory experiment with a swinging iron bar to test his hypothesis that a moving mass produces a magnetic field. He showed experimentally that the field given by (8), assuming that m is taken as the mass of the earth and v the relative velocity of the iron bar, did not exist. Other arguments against the hypothesis are given in Section 5.

It was probably this disproof of the existence of the field given by (8) which led to the later lack of interest in the approximate validity for the sun and earth of the result expressed by (7). This difficulty about translational, as opposed to rotary, motion had already been discussed by Schuster in 1912, and will be taken up again in Section 5.

Schlomka[17] (1933) has treated in some detail a theory based essentially on Schuster's hypothesis of unequal long-range Coulomb forces between like and unlike particles.

Haalck[18] (1937–38) attributes the required charge separation not to a difference in the Coulomb forces between electrons and nuclei, but to the short-range forces between electrons and molecules, that is, to the forces responsible for the elastic properties of materials. He assumes that such forces would lead to a charge separation proportional to some power of the radius, with a maximum at the earth's centre.

Swann[19] (1927) worked out an elaborate theory based on a small arbitrary modification of the electro-dynamical equations, chosen so as to give the required magnetic field without the unwanted electric field. However, Swann's fundamental hypothesis was that the magnetic field of a rotating body was proportional to $\rho\omega^4 R^4$ rather than to $\rho\omega R^2$ as given by (11a). This was adopted to avoid the difficulty of translational motion by assuming that the magnetic field due to a mass element depended on certain time derivatives of its velocity, and so is zero for uniform translational motion. Swann chose this particular form since it does give correctly the ratio of the field of the sun and the earth. But it also predicts relatively large fields for rotating bodies on a laboratory scale, and these were later shown by Swann and Longacre[20] (1928) not to exist, thus refuting the theory at least for small bodies. Other objections to Swann's theory are that it is unlikely that the vector quantity P will depend on an even power of the vector ω, and that the theory in no way gives the correct numerical value of the magnetic moment except by the introduction of arbitrary parameters.

The Case for a General Theory.

Chapman and Bartels[2] (1940, vol. 2, p. 707) discuss these various theories in some detail but do not give much prominence to the particular parts of the work of Sutherland, Schuster, Wilson and Angenheister, which together establish the results already given. They sum up on the whole against a theory of the type here called a *general* theory and in favour of a *specific* theory of some type; but they do not find that any then existing specific theory is tenable. Their main reasons for the rejection of a general theory lay in the facts of the obliquity of the magnetic and rotational axes, which is 4° for the sun and 12° for the earth, and the existence of the secular variation. For the earth this means that a field amounting to some 10 per cent of the main symmetrical field would remain to be explained even if a general theory served to explain the main field. It seems to me, however, that, given a general explanation of the main field, then the convective motions, etc., that must exist in the earth's interior may well be found to modify the main field sufficiently to produce the observed field.

It is surely far more difficult to find a specific theory that will give the two striking results: (*a*) that the magnetic momenta of the sun and the earth are nearly proportional to their angular momenta—the range of variation of both being more than 10^8 to 1; and (*b*) that the constant of proportionality is nearly $G^{1/2}/c$, than it is to explain a deviation in the directions of the two axes and the existence of the secular variation.

It seems extremely unlikely that the approximate validity of equation (7) could be accidental. Its simplicity, involving as it does only the two macroscopic constants G and c, is in striking contrast to the complexity and arbitrary character of all special theories hitherto put forward, and their failure so far to provide a quantitative explanation either of the field of the earth or of the sun, far less of both.

The occurrence only of the constant $G^{1/2}/c$ multiplying the angular momentum U seems to exclude, except by way of a remarkable number of numerical accidents, the possibility that any specific properties of the rotating body, other than its size, mass and rotation, can determine its magnetic field.

If P does depend only on the macroscopic quantities M, R, ω, G, c, then dimensional considerations can be used to find the possible functional forms. Restricting our consideration to cases where P is proportional to M, we find that P can be put in the form

$$P \propto G^{1/2}c^{-1}\omega M R^2 f(\omega R/c). \quad . \quad . \quad (13)$$

For $f(\omega R/c)$ = constant, this gives our original expression (7). Since P must vary as an odd power of ω, the next likely expression is given by taking $f(\omega R/c) = (\omega R/c)^2$, giving

$$P \propto G^{1/2}c^{-3}\omega^3 M R^4. \quad . \quad . \quad . \quad (14)$$

Now our original expression gives both the observed variation of P with M, ω and R and the rough correct numerical magnitude, while the second gives neither one nor the other. It will be noticed that the second expression differs from the first by the factor $(\omega R/c) = v/c$, when v is the peripheral velocity. It is, of course, probable that at very high peripheral speeds a relativity correction involving $(v/c)^2$ would have to be introduced.

3. The Angular Momentum of a Star

As has already been explained, the approximate validity of (7) was first noted by comparing the magnetic moments of the earth and sun, assuming both to have uniform density. This, however, is far from being the case, especially for the sun, so it is necessary to take into account the central condensation of these bodies when calculating their angular momentum U.

It is convenient to introduce the ratio

$$k = I/I_0 \quad . \quad . \quad . \quad . \quad . \quad (15)$$

of the moment of inertia of a given centrally condensed sphere to that of a sphere of the same radius, angular velocity, and with a uniform density equal to the mean density of the centrally condensed sphere. Then, instead of (1), we have

$$U = \frac{2}{5}k\omega MR^2. \quad . \quad . \quad . \quad (16)$$

For the earth and major planets k is known from the work of Jeffries[21] (1924, 1937). For the sun and other stars, its value must be calculated assuming some given stellar model. First, we have the Emden polytropic gas spheres for which Eddington[22] (1926) quotes the density distributions for three values of the index n. Then there is the more recent point convective model of Cowling[23] (1935) for which new numerical calculations have been made by Blanch, Lowan, Marshak and Bethe[24] (1941) and Marshak and Blanch[25] (1946).

From their density distributions the values of k have been calculated roughly by graphical integration, leading to the figures given in Table 3, together with the ratio of the central density ρ_0 to the mean density $\bar{\rho}$.

TABLE 3. CENTRAL DENSITY ρ_0 AND RELATIVE MOMENT OF INERTIA k OF STELLAR BODIES

	$\rho_0/\bar{\rho}$	$k = I/I_0$
Uniform sphere	1·00	1·00
Polytrope $n = 2$	11·4	0·40
,, $n = 2·5$	24·1	0·28
,, $n = 3$	54·3	0·20
Point convective model	79·3	0·14
Earth	3·3	0·88
Jupiter	?	0·66

There is thus considerable uncertainty in the value of k for the sun. In what follows, we will assume the value 0·16 as the mean for the point convective model, and the polytrope with $n = 3$.

Non-uniform Rotation.

From considerations of stability it appears probable that the angular rotation of a gaseous stellar body cannot be uniform, but it is likely to increase inwards (see discussion by Milne[26], 1930, p. 241). On the other hand, it is known that the surface rotation of the sun is about 40 per cent slower at the poles than at the equator. Though so far there appears to be no certain way of estimating the magnitude of this effect, it is convenient to introduce a quantity defined by

$$\eta = U/U_c,$$

where U is the true angular momentum, and U_0 is the angular momentum calculated from the observed peripheral equatorial velocity, taking into account the variation of density but not the variation of the angular velocity. Then we know that η is of the order of, but probably rather greater than, unity.

I am indebted to Prof. Cowling for informing me that the mean period of rotation of the whole mass of the sun is very uncertain, but is probably not shorter than ten days, though it may be actually more than twenty-five days. This gives a limit of η between 2·5 and, say, 0·7.

We have therefore the following expression for the angular momentum of a rotating celestial body:

$$U = \frac{2}{5}k\eta\omega MR^2, \quad . \quad . \quad . \quad (17)$$

and so, with (2) and (7)

$$H_P = \frac{2}{5}\beta G^{1/2}k\eta\omega M/Rc, \quad . \quad . \quad . \quad (18)$$

where ω is the observed angular velocity of the surface at the equator. For a few stars the values of M and R are known accurately, but in general they have to be deduced statistically. The values of k and η can, of course, only be derived from some theoretical model of the interior of the star.

4. The Magnetic Field of a Rotating Star

4.1. *Babcock's Measurements on* 78 *Virginis*

It has long been known that many stars are rotating much faster than the sun, and so, on our hypothesis that equation (7) has general validity, should have large magnetic fields. But it is only quite recently that the magnetic field of any star except the sun has been measured. This has been achieved by H. W. Babcock[1] (1947) for 78 Virginis (spectral type $A2$), and, as has been explained in Section 1, it is satisfactory to find that within the rather large error of the measurement of the magnetic field and the statistical uncertainty of the estimation of the mass, radius and angular velocity, the results are in agreement with expectation, though the relation between the directions of the magnetic field and rotation is not known.

The rotational velocity of stars is measured by the broadening of spectral lines due to the Doppler effect of the light from different portions of the disk. A general account of the method is given by Elvey[27] (1930), Rosseland[28] (1936, p. 202) and Becker[29] (1942, p. 66). Stars of early spectral types O, B and A and early F are usually found to be in rapid rotation, with a most frequent peripheral velocity of about 100 km./sec., compared with the 2 km./sec. peripheral velocity of the sun (type $G0$). A small fraction have velocities of more than 200 km./sec. (see Table 4). The rotations seem to disappear rather suddenly between $F2$ and $F5$ types, and no observable rotations, that is, with peripheral velocities more than, say, 20 km./sec., have been observed for later spectral types. A few stars of the early types have, however, fine spectral lines, and this is interpreted as indicating that their rotational axes are parallel to the line of sight. It is only on such stars that the Zeeman effect can at present be measured.

Babcock's measurements on 78 Virginis give a polar field of 1,500 gauss. He assumes a peripheral velocity of 60 km./sec., and compares these figures with the field of 53 gauss and velocity of 2 km./sec. for the sun, concluding that the field is proportional to the peripheral velocity. This, however, lacks physical plausibility.

To test equation (7) we need M, R and ω. From tables given by Becker[29] (1942, p. 64) for the different spectral classes, we find for a star of type $A2$ that $M = 2·3$ and $R = 2·0$ in terms of values for the sun. From data on rotation given by Becker (p. 69) and reproduced in Table 4, the median peripheral velocity for A type stars appears to be about 100 km./sec. rather than the value of 60 km./sec. assumed by Babcock. The angular velocity ω must therefore be twenty-five times that of the sun, that is, nearly the same as for the earth.

TABLE 4. DISTRIBUTION OF ROTATIONAL PERIPHERAL VELOCITIES FOR STARS OF EARLY SPECTRAL TYPES, BECKER[29] (1912)

Velocity (km./sec.)	Type *O, B* (%)	Type *A* (%)	Velocity (km./sec.)	Type *O, B* (%)	Type *A* (%)
25	—	13	150	15	12
50	27	17	175	—	8
75	—	11	200	4	7
100	53	10	225	—	4
125	—	14	250	1	1

Assuming that k and η have the same values for the sun and 78 Virginis, the ratio of their polar fields, according to (11), should be proportional to $\omega M/R$, and so should have the value 29, whereas the observed value is 28. Considering the statistical nature of the data for the star shown clearly in Table 4, the closeness of the above agreement must be considered quite accidental. The direction of the magnetic field was determined, but not, of course, the direction of rotation. So no comparison of the signs of P and U is possible for this star.

4.2. *Collected Data for the Earth, Sun and 78 Virginis.*

In Table 5, we have given collected data for the three bodies. For the earth, the component along the axis of rotation of the dipole moment as given by Chapman[30] (1943) is used.

TABLE 5. RATIO P/U ALLOWING FOR CENTRAL CONDENSATION

	Magnetic moment $P=\frac{1}{2}H_PR^3$	k	Angular momentum $U=\frac{2}{5}k\omega MR^2$	$\frac{P}{U}$	$\beta=\frac{P}{U}\div\frac{G^{1/2}}{2c}$
Earth	$7{\cdot}9\times10^{25}$	0·88	$6{\cdot}22\times10^{40}$	$1{\cdot}30\times10^{-15}$	0·30
Sun	$8{\cdot}9\times10^{33}$	0·16	$1{\cdot}80\times10^{48}$	$4{\cdot}9\times10^{-15}$	1·14
78 Vir.	$2{\cdot}1\times10^{36}$	0·16	$4{\cdot}2\times10^{50}$	$5{\cdot}0\times10^{-15}$	1·16

Quite recently, one uncertainty, that of the nature and magnitude of the sun's dipole field, has been cleared up. Hale's early measurements showed a much more rapid decrease of H with height in the sun's atmosphere than would correspond to the field of a dipole. However, the work of Thiessen[31] (1946) seems finally to have established the existence of a dipole field for the sun, and gives a value for the polar field of 53 ± 12 gauss.

In the last column of Table 5 are given the values of β, calculated from (7) by inserting the observed values of P and U and taking $G^{1/2}/2c = 4{\cdot}31 \times 10^{-15}$ cm.$^{1/2}$ gm.$^{-1/2}$. It will be noticed that β is nearly unity for the sun and 78 Virginis, but about 0·3 for the earth; the latter fact had been originally noticed by Wilson[15] (1923). Alternatively, β can be obtained directly from the expression

$$\beta = \frac{5}{2} H_P Rc/k\omega MG^{1/2}. \quad . \quad . \quad . \quad (18a)$$

This equation is convenient as showing the effect on β of errors in the various quantities.

It is noteworthy that the close proportionality between P and U for the earth and sun, found on the assumption of uniform densities (Section 1), is destroyed by taking into account the central condensation of the sun and the stars.

In Table 6 the observed relative values of H_P for the three bodies are compared with the values calculated from (7), assuming that the angular momenta are calculated from equation (1) for uniform density, and equation (16) for centrally condensed spheres.

TABLE 6. OBSERVED AND CALCULATED POLAR FIELD

	H_P (observed)		Uniform density	Central condensation	
	gauss	relative	$\frac{M\omega}{R}$	k	$\frac{M\omega R}{R}$ (rel.)
Earth	0·61	1·0	1·0	1·0	1·0
Sun	53±12	86	121	0·16	20
78 Vir.	1500	2450	3500	0·16	550

4.3. *Possibility of Further Tests on Stars of the Main Sequence.*

Clearly, further measurements of the magnitude and direction of the magnetic field of highly rotating stars are of great importance to test the theory. Babcock[1] (1947) has stated that it might be possible to find the relation between the directions of H and ω on a visual binary. As shown in Table 4, some stars of the early spectral classes, rather similar to 78 Virginis, have rotational velocities about 2·5 times as high (see also Struve[32], 1930, Westgate[33], 1933, 1934). Such stars should therefore have a polar field of about 4,000 gauss.

The maximum magnetic field is set by the Roche Limit giving the maximum angular velocity ω_m for stability. This is given by

$$\omega_m = 1{\cdot}52\, G^{1/2}\,\bar{\rho}^{1/2}, \quad . \quad . \quad . \quad . \quad (19)$$

where $\bar{\rho}$ is the mean density (Jeans[34], 1928, p. 246). This suggests that angular rotations up to some four times that of 78 Virginis are possible, thus giving a maximum field for this type of star of about 6,000 gauss. If we insert ω_m from (19) in (11a), we see that the maximum possible field H_m of a star is proportional to $\bar{\rho}^{3/2} R^2$. From the variation of $\bar{\rho}$ and R with spectral type (ref. 1, p. 62), we see that H_m varies rather slowly with spectral type along the main series. Relative to the value for the sun (G0), we find $H_m = 1{\cdot}2$ for (M0) and 0·5 for (B0) type. These later types, though apparently not normally rotating fast, are capable dynamically of giving greater fields than early types.

The most satisfactory test would, of course, be on a star for which the magnitude and direction of both the magnetic field and angular velocity could be measured directly, rather than having to rely on a statistical argument for the determination of the rotation, as for 78 Virginis. It seems that this might, in principle, be done by measuring both the Zeeman effect and the Doppler effect of the light from the nearly eclipsed edge of the rear component of an eclipsing binary. But probably the experimental difficulties would be very great.

4.4. *The White Dwarfs.*

The white dwarfs should also have a large field if they are rotating with comparable angular velocities to the sun, owing to the high values of the ratio M/R on which the field depends (equation 11). The values for several white dwarfs of this ratio, which is also the ratio governing the red shift, are between twenty and thirty times that of the sun (Russell[35], 1945, p. 760), and so should give a field of about 1,300 gauss. If, however, for example, the dark companion of Sirius has the same angular velocity of rotation as Sirius itself, that is, eight days, its magnetic field would be about 5,000 gauss.

It has been suggested by Kuiper[36] (1941) that possibly white dwarfs have angular *momenta* comparable with that of the sun, as would be expected if they are formed by the collapse of such stars. Now Sirius B has nearly the same mass as the sun but only a fiftieth of its radius. If its angular momentum is equal to that of the sun, so will be, according to our hypothesis, its magnetic moment. Consequently its magnetic field will be 50^3 times as great; that is, its equatorial field will be 3×10^6 gauss.

Now the most prominent lines in the spectra of white dwarfs, and often the only lines, are the hydrogen Balmer series. These lines are, however, much broader than for normal main sequence stars. This greater breadth is generally ascribed to pressure broadening, that is, to the Stark effect due to atomic collisions, which should be exceptionally great in these stars owing to the high pressure associated with the very intense gravitational fields. It appears from the discussion by Kuiper[36] (1941) that a rough quantitative explanation on these lines is possible.

It is, however, interesting to note that a magnetic field of a few million gauss will also produce a broadening of the observed magnitude. For the double Zeeman separation of a normal triplet of the wave-length of $H\gamma$ is nearly 2×10^{-5} A./gauss, so the breadth of the Zeeman pattern should be about 60A. It must be remembered that owing to the Paschen–Back effect the Balmer lines will give nearly the normal triplet. Since the polar field is twice the equatorial field, this calculated breadth will approximately represent the double width to half intensity of the light from the star as a whole. Sirius B itself seems to have rather finer Balmer lines than 60A., and also some metallic lines. However, a number of white dwarfs, for example, 40 Eridani B and Wulf 1346 have Balmer lines of widths of about 50A. (Kuiper[36], 1941). Thus it cannot be considered unplausible to suppose that the line widths of white dwarfs are markedly greater than main sequence stars, not only because of a large Stark effect but also in part because of a large Zeeman effect. The comparison given by Kuiper of the spectra of 40 Eridani B with a comparison star shows that the line width of the latter, probably to be attributed to pressure broadening, would be enough to obscure the typical double-triplet structure of a Zeeman pattern in the white dwarf.

Many of these stars show a rather fine central core to the broad Balmer lines which is difficult to explain as due to Stark effect; and it is possible that this is caused by the undisplaced components of the Zeeman pattern, which will be the same all over the disk.

It is perhaps significant that most of the white dwarfs which are believed to be still smaller than Sirius B show no Balmer lines at all (Wulf, 489, 457, 219) or very shallow ones (AC. 70, 8247). One star, Ross 627, is anomalous in this respect, as it has rather fine lines but is nevertheless believed to be very dense.

In the spectrum of (AC. 70, 8247) there are two shallow lines more than 100 A. in breadth and centred on 4480 A. and 4140 A. If these are identified with $H\gamma$ (4341) and $H\delta$ (4102) and their breadth attributed to Zeeman effect, the required magnetic field is about 10^7 gauss. Taking Kuiper's estimate (ref. 36, p. 234) of the radius as 0·004 of that of the sun, the magnetic moment and so the angular momentum of the star relative to the sun will be $(10^7/25) \times (0{\cdot}004)^3 = 0{\cdot}024$. It is, however, possible that the observed shallow lines do not represent the whole absorption line but only the finer central core. In this case the real breadth will be considerably larger than 100 A., and so the angular momentum also will be larger—thus bringing it nearer to that of the sun.

Clearly, polarization measurements on the spectra of the white dwarfs are urgently needed, and calculations of the line profiles which would result from the combination of the Zeeman effect in large fields with pressure broadening.

I am indebted to Prof. H. H. Plaskett for pointing out that there is one white dwarf, Wolf 489 (see ref. 36, p. 211), which lends support to the explanation of the broadening by Zeeman rather than Stark effect. This star is unusual in being of a later colour type ($G8$) and so should show strong lines of ionized calcium. In fact, it shows no lines at all. Since Ca$^+$ lines are very much less influenced by the Stark effect than hydrogen lines, it is difficult to explain their absence as due to the Stark effect. Thus the Zeeman effect, to which the H and Ca$^+$ lines are equally sensitive, provides a more plausible explanation.

Since the Zeeman breadth $\Delta \lambda_Z$ is proportional to the surface magnetic field and so, according to (2) and (7), to U/R^3, while the Doppler breadth $\Delta \lambda_D$ is proportional to the peripheral velocity and so to $U/M.R$, the ratio $\Delta \lambda_Z/\Delta \lambda_D$ is proportional to M/R^2 and so is independent of the rotation. For very small and dense stars the Zeeman breadth becomes greater than the Doppler breadth. For Sirius B, $\Delta \lambda_Z$ is about twenty times $\Delta \lambda_D$. The two breadths will be equal for a star of about the sun's mass, which has a radius about five times that of Sirius B. The period of rotation of Sirius B, if it has the same angular momentum as the sun, is fifteen minutes, and its peripheral velocity 100 km./sec. Owing to the high density, the limiting period set by the Roche limit is about forty seconds.

4.5. *The Major Planets.*

Another interesting possibility is that Jupiter might have a measurable field. Take the value of k as 0·66, as given by Jeffries[21], with $R = 7{\cdot}0 \times 10^9$ cm., $\bar{\rho} = 1{\cdot}35$, $T = 9{\cdot}8$ hours, we find from (18a) that the polar field is about 30 gauss, using the value of β for the earth, and 120 gauss with the value for the sun. Probably such a small field would be unmeasurable, as the only spectral lines available are apparently the absorption bands of methane and ammonia; the low temperature 150° abs. would, however, help by making the lines narrow.

5. Theoretical Discussion

5.1. As has already been explained, early attempts to explain the magnetic field of the earth on the lines of a general theory tentatively assumed that the earth was in some way electrically charged. Since the earth has a very small external electric field, it was necessary to assume that the net charge was zero, and so a separation of positive and negative charges within the earth was postulated. To explain the sign of the magnetic field, it was necessary to suppose that the negative distribution was displaced outwards. A special case of such a distribution (Sutherland[14], 1904) is that of a uniform positive volume charge combined with negative surface charge of equal total magnitude.

A charge separation theory of this type has the great merit of explaining very simply the existence of a magnetic field due to a rotating body, and the absence of a magnetic field due to pure translational motion. Provided, however, that the normal laws of electro-magnetism are assumed, it is quite impossible to believe in the existence of a real charge-separation of the required magnitude. This is given by (12), and for the earth is of the order of 10^{-3} E.S.U., or 10^6 electrons per unit volume. But such a charge distribution implies an electric field inside the earth of the order of 10^8 volts/cm., which is greater than the dielectric strength of any known material. In the sun its non-existence is still more obvious. Since the conductivity both of the central core of the earth and of the ionized matter in the sun are relatively high, any such charges which were produced by any static E.M.F. would very rapidly be conducted away. Chapman[37] (1928) and Cowling[6] (1945) have calculated that the conductivity of the matter at the sun's centre is of the same order as that of copper at normal temperature.

Actually there will, of course, be some separation of positive and negative charges in an ionized gas in a gravitational field, due to the large difference in mass between the electrons and the positive ions. Pannekoek[38] (1922) and Rosseland[39] (1924) have treated this question (see ref. 22, 1926) and have proved from the Maxwell–Boltzmann equation that a charge density of magnitude

$$\sigma_e = G\rho\mu/e, \quad . \quad . \quad . \quad . \qquad (20)$$

when μ is the mass of the positive ions and e is the electronic charge, will be produced by the tendency of the electrons to move to regions of higher gravitational potential.

For the sun, the mean molecular weight is about 2·2 in terms of the hydrogen atom. Comparing (20) with (12), we see that the ratio of the charge density and so the electric field, due to this separation of electrons and ions in the gravitation field, to the charge density and electric field necessary to explain the magnetic field of the earth, is about 10^{-17}. Essentially the same result was obtained earlier by Brunt[4] (1913) in a less general form. The sign of the charge distribution is the same as that required to explain the magnetic field, that is, the negative charge is outermost.

Cowling[40] (1929) has pointed out that when an ionized medium in a gravitational field is moving at right angles to a magnetic field, then the electric field due to the separation of the charges is considerably greater than that given by (20). It is still, however, far too small to explain the observed magnetic moments.

If the normal electro-magnetic equations are assumed valid, it is clear that no adequate real charge separation can exist. Thus some alteration in the fundamental equations seems inevitable. Further, it is difficult to believe that any possible alteration of the electro-dynamical equation can allow the existence of a real charge density in the earth and sun of the required magnitude. Still, it is possible that the charge separation theories of Schuster, Schlomka and others, which depend on the hypothesis of lack of exact equality between protons and electrons, etc., may repay further study.

Another type of alteration of the electro-magnetic equation is that proposed by H. A. Wilson, who postulated that a mass in moving with velocity v, even though electrically neutral, produces a magnetic field given by (8).

This hypothesis, however, is certainly untrue, if v is interpreted as a relative translational velocity. For example, an observer in an aircraft moving at 500 km./hr. relative to the earth can be considered as at rest with the earth moving past him at the same velocity. Thus, according to (8), he should observe a magnetic field of the order of 1 gauss and with a direction quite different from the actual field of the earth. Again Wilson disproved this relation by a laboratory experiment.

There is also, of course, a theoretical objection to the existence of any magnetic field associated with the translational motion of a neutral mass. For the normal Lorentz transformations for free space show that the magnetic field given by (8) can only exist if the assumed 'neutral' mass has an electric charge $Q \sim G^{1/2}m$; this contradicts the assumption that the mass is uncharged.

We must conclude, therefore, that a neutral mass with a pure translational velocity does not produce a magnetic field according to (8). However, for the purpose of explaining equation (7), it may not be necessary to assume that (8) is true for pure translational motion. If, for example, the velocity of a mass element δm is interpreted as that velocity relative to an observer which is produced by the absolute rotation of the body, then one can use (8) to explain (7) without necessarily concluding that a neutral mass in pure translational motion produces a magnetic field. We conclude, therefore, that equation (8), with an additional multiplying factor β, may possibly provide a tentative explanation of (7), provided v is defined as the relative velocity due to rotation as measured with reference to the inertial frame of the universe, that is, by the equation $v = [\omega.R]$, when ω is the measured absolute rotation and R the radius vector from the centre of gravity.

It is not, however, clear to me whether it is, in fact, possible to retain (8) for rotational motion and deny it for translational motion without some far-reaching alteration in the electro-magnetic and dynamical equations. No difficulty occurs in the application to a single rigid rotating body, but how to avoid difficulties in connexion with the orbital motion of, say, the planets or a double star is not so clear. As has already been pointed out, this difficulty does not occur on the hypothesis of a real charge separation. For here we have two equations of type (9), one with Q and H positive and one with them negative. It is the cancellation of the magnetic fields from the opposite charges which give a magnetic field for rotational but not for translational motion. The problem is whether one can obtain the same result with the single equation (8). If this proves impossible, then one may be forced back on some theory equivalent to the assumption of virtual electric charges, that is, charges which produce a magnetic field but not an electric field. A hint of how this might be done may possibly be obtained from considering the field of the neutron.

At the time of the first attempt to explain the magnetic field of the earth, no magnetic fields were known except those associated with a movement of electric charges or with a time variation of electric intensity. This is no longer the case, since it is now known that the neutron has a magnetic moment. This amounts to 1·80 Bohr nuclear magnetons, and the magnetic moment and spin vectors (angular momentum) are opposite in direction, as they are for the earth or sun. In some current meson-field theories, the difference between the magnetic moments of the neutron and proton are attributed to the existence of virtual mesons, thus bringing in virtual but not real electric charges. Possibly this might be taken as a hint that the magnetic field of a massive rotating body might be attributed to such a virtual charge separation. The observed linear variation of H with ω shows that such a virtual charge separation cannot be the result of the rotation but must be a property of a massive body at rest.

Since the ratio P/U for a neutron is about 10^{-3} of that for a Bohr atomic magneton, it can be seen from (6) that there is no obvious numerical relationship between P/U for a massive body and P/U for a neutron, unless one quite arbitrarily introduces such a non-dimensional ratio as $e^2/hc = 1{\cdot}16 \times 10^{-3}$.

It seems at present impossible to find an explanation of the fact that $\beta \cong 0{\cdot}3$ for the earth and about unity for the sun and 78 Virginis. The screening effect of ferromagnetic materials in the earth's crust could not possibly give an effect so large as 1 per cent. It is, of course, possible that the fault lies with the values of k and η assumed for the sun and 78 Virginis. If the products $k\eta$ were in reality three times as large as assumed, the discrepancy would be removed. But so also would be the attractive feature that β is nearly unity for the sun and 78 Virginis.

An alternative possibility is that the difference is due to some small effect of the *specific* properties of terrestrial or stellar matter, superimposed on the *general* mechanism responsible for the existence and order of magnitude of the main field. One might, perhaps, attribute the difference of the value of β to, say, the proportion of free electrons in the matter, or to the ratio of protons to neutrons.

Clearly the experimental result (7) and its hypothetical explanation (8) are to be considered as holding only for the non-relativistic case. When peripheral velocities comparable with c occur, modifications are clearly to be expected.

In general, it seems very probable that a satisfactory explanation of equation (7) will not be found except within the structure of a unified field theory. In this connexion equation (6) may be of special significance in view of the important part that the non-dimensional rate $G^{1/2}m/e$ must play in any such theory.

5.2. *The Magnetic Field of an Asymmetric Body.*

We have implicitly assumed so far that the static magnetic field given by (7) for a sphere must ultimately be expressible as an integral over all parts of the body. Though equation (8) represents one differential form which gives the observed result for a sphere, apart from the numerical factor β, we must inquire if there are likely to be solutions of a different type. For the following reasons this seems unlikely. First, the fact that, for a sphere, H is found experimentally to vary as ρ (see equation (11a)), implies that H must be expressible as the vector sum of contributions δH from each mass element considered separately. For if, for example, δH for a mass element depended not only on δm, but, say, also on the gravitational potential at the element, then H for the whole body would not be a linear function of ρ. If, therefore, we assume that each mass element gives an independent contribution to the total field, then (8) appears the only form which will give the observed linear dependence of H on ω.

It is possible, of course, that the correct solution is of the form of (9) rather than (8), where δQ is interpreted as some form of virtual charge taking both positive and negative values. If this is so, then δQ for any volume element may depend on the whole configuration of the body, as it would for a real charge separation, and not only on δm.

Until this question is settled, it is not possible to calculate the magnetic field of an asymmetric body, such as a massive ellipsoid rotating, say, about its shortest axis. This is of importance in connexion with possible laboratory experiments, as it might prove technically easier to measure the alternating field which one would expect from such an asymmetrical body, rather than the static field of a symmetrical one.

The general question then arises as to whether one can, in fact, extrapolate (7) and (8) to the laboratory scale. Though (7) holds experimentally roughly over a range of U of more than $10^{10}:1$ for the three astronomical bodies, does this justify the necessary extrapolation of $10^{28}:1$ from the earth to the case, say, of a bronze sphere of 1 metre diameter rotating at 100 r.p.s., which should give a field of about 10^{-8} gauss (see next section).

The physical conditions of the material of such a laboratory sphere differ so widely from that of the earth, not only in respect of size, but also of temperature, pressure and tension, ratio of gravitational to centrifugal forces, etc., that little can be concluded until a consistent theory of (7) has been found.

It may be noted that the separate ranges of R, ω and ρ for the three astronomical bodies are about $220:1$, $25:1$, and $14:1$, respectively. The extrapolation to a laboratory sphere involves an extrapolation of $1:10^{-7}$ for R, and $1:10^{7}$ for ω.

5.3. *Possibility of Laboratory Test.*

Assuming that the extrapolation is justified, we can calculate the maximum field from a sphere of given material. Giving β the value 0·30 as for the earth, the polar field of a rotating sphere is found from (11a) to be—

$$H_P = 1{\cdot}07 \times 10^{-15}\rho\omega R^2. \quad . \quad . \quad (20)$$

In this expression we have to insert the maximum possible value ωm rad./sec. consistent with the maximum safe tensile stress S gm./cm.^{2}; using for this the value for a disk given by Svedberg (1940), which can be put in the form

$$\omega m = 50\, S^{1/2}\rho^{-1/2}R^{-1}, \quad . \quad . \quad (21)$$

we find

$$H_P = 5{\cdot}4 \times 10^{-14}S^{1/2}\rho^{1/2}R. \quad . \quad . \quad (22)$$

We thus see that $H_P \propto R$, hence the advantage of a large body rotating correspondingly slowly. Taking $\rho = 8$, and, for example, $S = 3{\cdot}0 \times 10^6$ gm./cm.^{2} or 43,000 lb./sq. in., we find:

$$H_P = 2{\cdot}6 \times 10^{-10}R. \quad . \quad . \quad . \quad (23)$$

For a 1-metre sphere ($R = 50$ cm.), the maximum speed is 100 r.p.s. and $H_P = 1{\cdot}3 \times 10^{-8}$ gauss. For a 10-metre sphere, the speed is only 10 per sec. and the field is $1{\cdot}3 \times 10^{-7}$ gauss. If it should turn out that the correct value of β to take is that for the sun rather than that for the earth, these fields would be multiplied by three.

If an asymmetrical body of the same maximum linear dimensions were used, then one would obtain a smaller field than that given by a sphere; but the fact that it would be alternating might permit detection of this smaller field more easily than is possible for the static case.

The only experiment which appears to have been carried out to attempt to detect the magnetic field of a rotating body is that of Swann and Longacre[20] (1928), who spun a copper sphere of 10-cm. radius at 200 r.p.s. According to (20) the field should be about 10^{-9} gauss. The experimental method was only sensitive enough to show that no field so large as 10^{-4} gauss was produced.

BRITISH ECLIPSE EXPEDITION TO BRAZIL

IN consequence of the aeroplane disaster at Dakar in the early hours of April 13, the British expedition to observe the total eclipse of the sun of May 20 at Araxa in Brazil has been cancelled.

The programme approved by the Joint Permanent Eclipse Committee of the Royal Society and the Royal Astronomical Society comprised four items.

The profiles of the chromospheric lines were to be observed using a Michelson echelon grating. The apparatus devised provides for a succession of short exposures at several points of the sun's limb to study the variation of profile and intensity with height above the sun as the moon successively masks off the lower layers. Some indication was hoped for of transition from photospheric temperatures to the high excitation temperatures now attributed to the coronal regions.

The corona was to be photographed in its own green monochromatic radiation through a large aperture (13·5-cm.) Fabry–Perot étalon to gain information on internal motions or rotation and to determine the profile of the green line accurately, also with a view to temperature assessment. The plates of the étalon had a separation of just over 1 mm. and were aluminized to give a resolving power of some 400,000. The coronal image would be crossed by arcs of circular fringes the displacement or distortion of which would reveal the motions. These two instruments were designed by Dr. J. A. Carroll, now deputy for research and development to Controller of the Navy and scientific adviser to the Board of Admiralty, during his occupancy of the chair of natural philosophy at Aberdeen.

In addition, it was planned to determine the darkening towards the limb by using one of the infra-red photo-cells, developed at the Admiralty Research Laboratory, with suitable recording gear.

Observations to measure solar radio noise at a frequency of about 60 megacycles/sec. were also planned with the collaboration of the War Office and Ministry of Supply, apparatus having been prepared by Dr. J. S. Hey and Major S. J. Parsons.

Dr. Carroll had been asked to take charge of the expedition, its organisation and preparation by the Joint Permanent Eclipse Committee, assisted by Dr. A. Hunter from the Royal Observatory, Greenwich, and one or two others, depending on what could be organised in the time available. During the period of preparation, he succeeded Mr. A. P. Rowe in the chief scientific post at the Admiralty, and it was impracticable for him to give the time required for preparation of, and participation in, the expedition as originally contemplated. The specialized nature of the equipment made assistance hard to find. Dr. Alan Baxter, who had been on Prof. Carroll's staff in Aberdeen, was familiar with it and had participated substantially in its design and development there for use in Omsk in 1936, but he had become a principal scientific officer in the Royal Naval Scientific Service. The Board of Admiralty took the view that, in the circumstances, it was reasonable that they should advance pure scientific research by making their scientific officers' services available to the expedition. The remaining expert optical member required for the team was Mr. J. H. Strong, of the Spectroscopy and Astrophysics Department of the Imperial College of Science and Technology.

During the last few months of 1946 and the first three of 1947, the equipment was assembled, modified and tested by this team in a room made available at the Admiralty Research Laboratory and with assistance from the Laboratory's workshops. The intention was that the gear and three observers, Dr. Baxter, Dr. Hunter and Mr. Strong, should proceed by sea in time to give them a clear month on the site, they being joined about ten days before the eclipse day by Dr. Carroll and Major Parsons. Various factors, among them the fuel crisis in Britain, caused the last ship which could be relied upon to reach Rio de Janeiro in time to be one due to sail on March 11. This was only known a few days beforehand, and it was barely possible to complete testing, dismantle all instruments, pack them and get them on board, particularly as the fuel cuts and the weather had seriously slowed up the later stages of the work. However, the gear, with the exception of the Fabry–Perot étalon and certain parts of an image rotator used in the echelon spectrograph, was dispatched, and arrangements made for the three observers to go out by air a month later. In attempting landing at Dakar while the airfield there was fog-bound, the aeroplane carrying the observers broke up, Dr. Baxter being killed instantaneously, Mr. Strong receiving injuries which at first were thought not dangerous but later proved fatal (see p. 667). Dr. Hunter escaped with severe cuts and abrasions. An emergency party was tentatively arranged to fly out and carry on if the apparatus with Dr. Baxter was intact, but on word being received that the étalon plates were smashed and the image rotator parts missing, it was clear that the optical observations must be abandoned; and since the radio observer was dependent on assistance and facilities to be provided from the rest of the expedition, that part of the programme had to be abandoned too.

OBITUARIES

Dr. Alan Baxter and Mr. John H. Strong

The aeroplane disaster at Dakar on April 13 cost the lives of two young men of science, who were to take part in the observations of the total solar eclipse on May 20 (see p. 666).

In Dr. Baxter, the Royal Naval Scientific Service has lost one of its most valuable younger members. Born in 1910, he was educated at Manchester Central High School and the University of Manchester. He graduated with honours in mathematics and in physics, proceeded to research in microphotometry and X-rays under Prof. (now Sir Lawrence) Bragg, taking his M.Sc. in 1932 and a Ph.D. in 1935. In 1934 he joined the staff of the Natural Philosophy Department of the University of Aberdeen, later becoming a lecturer in physics. He had a conspicuous talent for perceiving the critical features of an experiment or proposed design of apparatus and a genius for simple investigation of essentials. This made him a very valuable member of the Admiralty scientific staff during the War. At Aberdeen he became interested in physical optics and astrophysics and carried out at a temporary observatory just outside the city of Aberdeen during the winters of 1937 and 1938 continuous spectrophotometric observations of the variable star Algol. The analysis of the results strongly suggested a more complex structure for Algol than a binary system; the advent of war prevented complete working out and publication of the results.

Baxter returned to Aberdeen for a time after the War, but found the Naval Scientific Service attractive to him and entered it as a permanent officer in 1946. He married in 1937 and is survived by his wife and two young daughters. He was a very welcome colleague, liked and respected, and his premature loss is deeply regretted.

Mr. John Strong was born in 1924 and educated at the Latymer Upper School and the Imperial College of Science and Technology, South Kensington. He graduated with honours in physics in 1944 and was appointed a demonstrator in the Spectroscopy and Astrophysics Department under Prof. H. Dingle and Sir George Thomson. He was carrying out research on a new type of arc source for spectroscopic analysis and was measuring the temperatures of various regions of the arc by means of the cyanogen bands. He was interested in interferometry and in astrophysics, and the eclipse observations offered excellent experience in his chosen field of research, which fitted him to be a valuable member of the observing team; and the Imperial College gladly agreed to make his services available. He was keen, energetic, eager and quick to learn.

It is particularly regrettable that what should have been valuable experience for these young men, from both of whom substantial contributions to science could confidently be expected, should have ended so tragically.

J. A. Carroll

Mr. W. J. Bean, M.V.O., I.S.O.

It is with deep regret that we have to record the death of William Jackson Bean, formerly curator of the Royal Botanic Gardens, Kew, who was known to every cultivator of hardy trees and shrubs by his standard three-volume work, "Trees and Shrubs Hardy in the British Isles". His death occurred on April 19 after a rather protracted illness, when within a few weeks of his eighty-fourth year. Born on May 26, 1863, in a village at the foot of the Yorkshire Wold, near Malton, his love for plant life was inherited, as for three generations his forbears had functioned as nurserymen. He was educated at Holgate School, York, and at the age of sixteen entered the famous gardens at Belvoir Castle to receive his early training in horticulture. At twenty years of age he entered the Royal Botanic Gardens, Kew, as a student gardener, and was quickly earmarked for promotion. After serving as sub-foreman in the Palm House and Orchid Houses, he was appointed foreman of the Temperate House, a position he occupied for several years before being transferred to the Arboretum as foreman in 1892.

During all this time and for several succeeding years, Bean contributed many articles to the horticultural press, chiefly *The Garden* and *The Gardeners' Chronicle*, while in 1890 he collaborated with the late William Watson in the writing of a book on "Orchids, Their Culture and Management". He was appointed assistant curator at Kew in 1900, with special charge of the Arboretum and Arboretum Herbarium. During the next few years he was sent abroad on various missions connected with arboriculture, chiefly to the United States of America and countries of Southern Europe.

At the instance of the late Sir William T. Thiselton-Dyer, Bean was entrusted with the preparation of a book descriptive of the Royal Botanic Gardens, Kew, and the work done there, which was published in 1908. It was in 1908 that he began serious work on the first two volumes of his great book on trees and shrubs, which took several years to complete; the third volume was prepared after his retirement. He also contributed many articles to the *Kew Bulletin of Miscellaneous Information*, mostly descriptive of his several journeys abroad and on new trees and shrubs. He was also a member of the committee appointed by King George V to advise on the trees in Windsor Great Park; was a member of the Floral Committee of the Royal Horticultural Society, and helped with the work of the Roads Beautifying Association from its inception.

Many honours came his way. In 1918 he was awarded the Victoria Medal of Honour by the Royal Horticultural Society, and in 1923 the same Society awarded him the Veitch Memorial Medal; later he was made an honorary member of the Society. In 1925, Bean was made a companion of the Imperial Service Order, and a few years later he received the membership of the Victorian Order for his work connected with the trees at Windsor. When Mr. Ernest Moore, the artist, was preparing for his exhibition of portraits of famous Yorkshiremen, Bean was selected as one of the number. The portrait was later purchased by Major Reginald Loder and presented to Kew. Bean retired in 1929, since when he lived in Kew within a stone's throw of his old office, spending a good deal of time in the Gardens and Herbarium, mostly at work. In his early days he found his recreation in cricket; later he played both lawn-tennis and golf.

Personally, I feel the loss of Mr. Bean very greatly. We were associated in one capacity or another for nearly forty years. For several years I was his subordinate in the Arboretum and succeeded him as foreman. I was then transferred to the museums where we had adjoining offices, he as assistant curator, I as an assistant in the museums. Later he became curator and I keeper of museums, positions which brought us into daily contact; and throughout the whole of the time we spent together never a disagreeable word passed between us. I last saw him in September 1946, when he was far from well. He had been a widower for many years and leaves one son and one daughter, to whom our sympathy is extended.

W. DALLIMORE

Prof. B. A. McSwiney, F.R.S.

MAY I please supplement the obituary notice in *Nature* of May 3 as follows: McSwiney, a Cork man, entered Trinity College, Dublin, in 1912, and I first met him when assigned to my section of a practical class for first-year medical students. He joined the O.T.C. and in September 1915 was commissioned as a Surgeon Sub-Lieutenant R.N.V.R., and served in H.M.S. *Staunch*. He graduated in 1916 and afterwards completed his medical course and received the Sc.D. degree. In anatomy and physiology we were both grateful pupils of Prof. A. F. Dixon and Sir William Thompson. The latter was drowned when the *Leinster* was sunk in 1918. He was on his way back to his post as scientific adviser to the Ministry of Food in London. Thompson was a pioneer in the study of nutrition; he and his assistant, Dr. Caldwell, fed themselves on a rigid diet for weeks on end, performed all necessary analyses and then varied the diet and noted the changes—this asceticism on top of arduous teaching work.

W. R. G. ATKINS

WE regret to announce the following deaths:

M. Edouard Chatton, formerly professor of zoology in the University of Montpellier, *Correspondant* for the Section of Anatomy and Zoology of the Paris Academy of Sciences, on April 23.

Prof. P. L. R. Lespieau, titular member of the Section of Chemistry of the Paris Academy of Sciences, on April 21, aged eighty-two years.

Mr. G. H. Tipper, formerly of the Geological Survey of India, on April 23.

Commander H. D. Warburg, formerly superintendent of tides, Admiralty, on May 7, aged seventy-eight.

NEWS and VIEWS

Royal Society: New Foreign Members

Prof. P. Karrer

PAUL KARRER, professor of chemistry in the University of Zurich, is one of the world's leading organic chemists. A pupil of Ehrlich, his work, beginning on chemotherapeutic problems, has since ranged over a wide field of organic chemistry. In particular he has achieved outstanding success in the study of substances of biological importance, notably in the vitamin field, and his work has played a large part in the spectacular successes of organic chemistry during the last twenty years. Karrer's work on the carotenoid pigments and the structural elucidation of vitamin A has been the basis of our present knowledge of the group, and mention may also be made of his constitutional work on the structure and synthesis of vitamin B_2 (riboflavin) and the vitamins E. Notable contributions, too, have been made by him to the chemistry of plant colouring matters of the anthocyanin type, and to our knowledge of the nature and mode of action of various co-enzymes. His laboratories have for long been a centre of attraction for workers from many countries. The brilliance of his achievements was recognized in 1937 by the award of a Nobel Prize. In addition to furthering chemistry by his research, Karrer has made a notable contribution to teaching through his text-book of organic chemistry, which enjoys a world-wide reputation.

Prof. H. C. Urey

PROF. H. C. UREY is known internationally for his great contributions to physical chemistry, and for his human approach to the problems of the social implications of science. His discovery of deuterium (heavy hydrogen) in water was recognized by the award of a Nobel Prize; but most important of all, this work established his interest in the problem of isotope separation. His development of chemical exchange, distillation and other methods of separation of isotopes has enabled American firms to market such materials as N^{15} as commercial commodities. Urey was one of the first in the United States to recognize that atomic weapons could be made, and his influence was crucial in the early history of the American project. He was identified closely with development at Columbia University of the diffusion process for separation of the uranium isotopes, and he visited Great Britain in this connexion at the height of the War. The menace to civilization presented by the discovery of atomic explosives was a challenge to Urey's social conscience, and after the War he devoted himself wholeheartedly to the public dissemination of information designed to impress the problem on the people of America and the rest of the world. Since the War ended, Urey has joined the new Institute which has been established in the University of Chicago to carry out academic researches in nuclear physics.

Prof. Øjvind Winge

PROF. ØJVIND WINGE has a record of extraordinary versatility and success in genetics and cytogenetics. In his early work with the fish *Lebistes reticulatus* he established the partial sex-linkage of a large group of genes determining the male polymorphism of the species. This was the first demonstration of the genetic activity of the pairing segment of the sex chromosome. Later he established genetic sex-determination in plants, and elucidated the nature of polyploidy. One remarkable success based on keen observation and appropriate experimentation was to demonstrate the balanced lethal situation established in the 'ever-sporting Stocks'. He has contributed much to the clarification of linkage groups in *Pisum*, and his recent work proving sexual reproduction in the yeasts is of fundamental importance for the genetics of micro-organisms.

James Alfred Ewing Medal Awarded to Sir Clifford Paterson, O.B.E., F.R.S.

On the joint recommendation of the presidents of the Royal Society and the Institution of Civil Engineers, the Council of the Institution of Civil Engineers has awarded the James Alfred Ewing Medal for 1946 to Sir Clifford Paterson, for specially meritorious contributions to the science of engineering in the field of research. The medal is awarded annually and was founded in 1936 in memory of Sir Alfred Ewing. Sir Clifford Paterson is in charge of the Research Laboratory of the General Electric Co., Ltd., Wembley, Middlesex. His contributions to the science of engineering in the field of research have extended over forty-five years. His work has been particularly outstanding in the development of new sources of illumination, in the study of their use and in their precision measurement. This work was carried out at the National Physical Laboratory until 1919 and later continued after he had joined the General Electric Co. More recently he has co-ordinated the work of numerous teams in connexion with outstanding developments in the use of high radio frequencies, thus making possible many of the vital new weapons of defence and offence. The production of special devices and particularly of new valves in quantity, at many stages of the War, kept our Services ahead of those of the enemy.

Royal Aeronautical Society Awards

The following medals have been awarded by the Council of the Royal Aeronautical Society:

Simms Gold Medal: awarded annually for the best paper read in any year before the Society on any science allied to aeronautics, such as meteorology, wireless telegraphy, instruments, to Prof. L. Aitchison, professor of industrial metallurgy, University of Birmingham;

George Taylor (of Australia) Gold Medal: awarded annually, at the discretion of the Council, for the most valuable paper submitted or read during the previous session, to Prof. A. R. Collar, Sir George White professor of aeronautical engineering, University of Bristol;

Wakefield Gold Medal: awarded annually to a member or non-member, to the designer of any invention or apparatus tending towards safety in flying, to Mr. Edwin Link, inventor of the 'Link trainer';

Society's Silver Medal: awarded, at the discretion of the Council, for an advance in aeronautical design, to Mr. W. G. Garter, chief designer, Gloster Aircraft Co., Ltd., for his work on the development and design of jet-propelled aircraft.

*R.*38 *Memorial Prize:* offered annually for the best paper received by the Society on some subject of a technical nature in the science of aeronautics, preference being given to papers which relate to airships, to Mr. J. K. Hardy, of the Royal Aircraft Establishment;

Edward Busk Memorial Prize: offered annually for the best paper received by the Society on some subject of a technical nature in connexion with aeroplanes (including seaplanes), to Mr. J. Smith, chief designer, Vickers Armstrongs, Ltd., Supermarine Works.

University of Glasgow: Freshwater Biological Laboratory and Insect Field Station

Important additions to the facilities available at the University of Glasgow for research and teaching in the field have recently been made available by the erection of two former Government huts on the shores of Loch Lomond, on a site kindly provided by Sir Iain Colquhoun, Bt., of Luss, and only some twenty miles distant from the University. The freshwater work is under the care of Dr. H. D. Slack, lecturer in freshwater biology, who has charge of one hut together with a motor-boat and dinghy. For the first time, continuous investigations can be carried out on the biology of freshwaters in Scotland, and the great size and exceptional depth of Loch Lomond render it an admirable site for such work. A generous gift of money by Sir Harold Bowden, Bt., for entomological research over a period of seven years, with particular reference to the biology of midges, is responsible for the erection and equipment of the second hut, and for the appointment of two research assistants who work under the direction of Mr. J. A. Downes, lecturer in entomology. The money is being shared with the Department of Natural History, University College, Dundee (University of St. Andrews), where the biology of *Monomorium* together with certain aspects of the midge problem are being studied by Prof. A. D. Peacock and assistants. This opportunity of co-operation between two Universities is particularly appreciated. The work of both centres is being co-ordinated with that of the Committee on the Control of Midges appointed by the Department of Health for Scotland. The Insect Field Station is also being used as a centre for the teaching of insect ecology. The University of Glasgow is thus in the fortunate position of being able to conduct field classes in freshwater biology and in insect ecology at Loch Lomond, and also to avail itself of the rapidly increasing facilities for marine biology available at the Millport Laboratory of the Scottish Marine Biological Association on the Clyde.

Further Education

It is the custom to greet a new magazine by asserting, often with more courtesy than truth, that it will fulfil a long-felt need. No such formula need apply to *Further Education*, published by the Turnstile Press, 10 Great Turnstile, London, W.C.1 (1*s*. 6*d*. monthly). The field which it covers is only beginning to be opened up, for a recognition of the need for further education too seldom troubled the education administrators of the last generation. The War did much to disclose the need and (what was more unexpected) did something to give it satisfaction. Many thousands of men and women in the Forces made their first acquaintance with 'serious pleasures', and have returned to civil life seeking the extension of that experience. The Education Act of 1944 envisaged a wide post-war enlargement of educational activity, and in its recent pamphlet, "Further Education", the Ministry set forth for the benefit of local education authorities many ideas and projects worthy of experiment and development. By March 31, 1948, local education authorities are obliged, with minor exceptions, to submit their schemes of further education to the Ministry. Many of them have already begun, and even the backward authorities will have something to promise, if not to display, by the appointed day.

Further education may henceforth hope to enjoy something better than the status of a lesser mandated territory. But a sentimental ardour for its benefits is not enough. What are especially required during these next few years are practicable schemes, reliable progress reports, and a brisk exchange of ideas. The first number of *Further Education* reveals a realistic purpose in providing these requirements, and is not afflicted by that sense of piety which so often besets ventures which want to advance human progress. In writing or talking about further education it is better to be hard-boiled than half-baked, and one of the characteristics of this new magazine is its preoccupation with ways and means. Its editor, Mr. J. Mackay Mure, is a fervent educationist, and his management of the paper's policy is an assurance that it will keep both feet on the ground. From the first number, it is plain that he intends to take full advantage of the terms of reference embodied in the paper's title. Further education has as much to do with vocational training as with the pursuit of culture, and the more we can be led to considering them as part of a common way of life the sooner shall we discern their relevance to each other. One final merit of this new monthly must be mentioned, and that is the lively quality of most of its articles. Nowhere has the boll-weevil of jargon made greater ravages than in educational journalism, and it is a welcome relief to find it entirely absent from these pages.

The Ray Society

THE annual general meeting of the Ray Society, now in its hundred and third year, was held on March 21. During the past year the Society lost by retirement owing to ill-health the services of its two senior officers, Sir Sidney Harmer, president since 1931, and Dr. W. T. Calman, secretary since 1919. Resolutions were passed unanimously thanking them for their distinguished services to the Society. Prof. F. E. Weiss having expressed the wish to retire from the office of honorary treasurer, his resignation was accepted with regret. Mr. A. D. Cotton resigned as vice-president. It was announced that Dr. Ben Dawes' volume on "The Trematoda of British Fishes" is ready for distribution, and, owing to the greatly increased costs of publication, this will form the issue to subscribers for the two years 1944 and 1945. The volume for 1946 will be Dr. Berrill's volume on "British Tunicates", but unexpected difficulties have caused delay in sending this work to press. A volume on Pennant's travels in Europe, edited by Prof. G. R. de Beer, is, however, nearly ready for press, and other works on a wide variety of subjects relating to the natural history of the British Isles are in active preparation. The following were elected officers and new members of council: *President*, Prof. G. R. de Beer; *Hon. Treasurer*, Mr. A. C. Townsend; *Hon. Secretary*, Dr. Errol I. White; *Vice-presidents*, Prof. F. E. Weiss, Mr. M. A. C. Hinton, Mr. E. R. Martin and Lieut.-Colonel Seymour Sewell; *Members of Council*, Mr. A. H. G. Alston, Dr. J. W. Evans, Mr. H. R. Hewer, Dr. George Taylor and Mr. Brian Vesey-Fitzgerald.

New British Ornithological Magazine

THE first issue of the new *Wild Birds Magazine* has appeared as a bi-monthly (until the paper ration increases) under the editorship of Mr. Eric Hardy and published from Friars Lodge, Friars Lane, Richmond, Surrey. There are illustrated articles dealing with bird-life at Manchester sewage farm (L. L. Turner), observations at the Yorkshire Naturalists' Union's new bird ringing and observation station at the Spurn by J. Lord, on a heronry (F. A. Lowe), birds of North Devon (N. V. Allen), Dungeness shingle (R. B. Burrowes), etc., while field notes include the first Lancashire record of the European bee-eater (*Merops apiaster*) in the autumn 1946, and the red-backed shrike using the same nesting site in two successive years. An abnormal immigration of waxwings and great grey shrikes into England during the recent winter is noted.

Industrial Uses of Methane

A PAMPHLET entitled "Chemicals from Methane", by Dr. J. P. Lawrie (pp. 24. Science Services, Ltd., 255 Russell Court, London, W.C.1, 1947. 3*s*.), deals with possible uses of methane from natural gas which, it is said, is available in important quantities in Great Britain. It is pointed out that large quantities of carbon black are imported from the United States, much of which is made there from natural gas, and it is suggested that this might well be made from native gas. Coke-oven gas is also rich in methane. Other products which might be obtained from methane, according to patent literature quoted, are hydrogen for ammonia synthesis, acetylene by exposure to an electric arc, methyl chloride by chlorination, hydrogen sulphide by reaction with sulphur, oxidation products such as methanol, formaldehyde, and formic acid, and nitromethane. A short bibliography is given.

Royal Institution

AT the anniversary meeting of the members of the Royal Institution held on May 1, the following officers were elected: *President*, Lord Rayleigh; *Secretary*, Prof. A. O. Rankine; *Treasurer*, Dr. R. E. Slade; *Managers*, Prof. E. N. da C. Andrade, Mr. M. G. Bennett, Prof. H. V. A. Briscoe, Major W. H. Cadman, Sir John Craig, Dr. C. H. Desch, Sir Alfred Egerton, Dr. E. V. Evans, Dr. W. Jevons, Colonel E. E. B. Mackintosh, Mr. G. S. W. Marlow, Prof. L. C. Martin, Sir Richard Paget, Sir Clifford Patterson, Sir Geoffrey Taylor; *Visitors*, Mr. J. J. Abraham, Mr. W. E. Watson Baker, Dr. J. H. Brinkworth, Mr. D. I. Duveen, Mr. F. P. Dunn, Mr. P. Evans, Dr. A. T. Fraser, Sir William Halcrow, Prof. F. L. Hopwood, Mr. L. B. W. Jolley, Mr. D. Northall-Laurie, Dr. E. Talbot Paris, Sir Harry Railing, Prof. D. V. Thompson, Prof. H. E. Watson.

Physical Society: Election of Officers

THE following have been elected officers for 1947–48 of the Physical Society: *President*, Prof. G. I. Finch; *Vice-Presidents*, Sir Edward Appleton, Mr. A. J. Philpot, Prof. H. R. Robinson, Dr. W. D. Wright; *Hon. Secretaries*, Dr. W. Jevons, Dr. H. H. Hopkins; *Hon. Foreign Secretary*, Prof. E. N. da C. Andrade; *Hon. Treasurer*, Dr. H. Shaw; *Hon. Librarian*, Dr. R. W. B. Pearse; *Members of Council*, Dr. W. S. Stiles, Dr. C. H. Collie, Prof. J. D. Bernal, Dr. D. Roaf, Dr. A. C. G. Menzies, Prof. R. E. Peierls, Dr. F. C. Toy, Prof. J. F. Allen, Mr. J. H.

Awbery, Prof. L. F. Bates, Dr. R. C. Evans, Dr. C. E. Wynn-Williams.

The officers for 1947-48 of the four Groups of the Society are as follows: Colour Group: *Chairman*, Mr. J. G. Holmes; *Hon. Secretary*, Dr. W. D. Wright; Optical Group: *Chairman*, Prof. L. C. Martin; *Hon. Secretary*, Mr. E. W. H. Selwyn; Low-Temperature Group: *Chairman*, Sir Alfred Egerton; *Hon. Secretary*, Mr. G. G. Haselden; Acoustics Group: *Chairman*, Mr. H. L. Kirke; *Hon. Secretaries*, Mr. W. H. Allen and Mr. A. T. Pickles.

University of Glasgow: Appointments

The following appointments in the University of Glasgow have been announced: Prof. G. W. Wishart, professor of physiological chemistry, is to become director of post-graduate medical education. Mr. J. R. Anderson has been appointed lecturer in pathology; Dr. W. F. Anderson, lecturer in materia medica; Dr. J. C. D. Brand (of King's College, London), lecturer in chemistry; Dr. S. A. Hutchinson (formerly with the Distillers' Co., Ltd.), lecturer in botany; and Mr. A. C. Robb, Nuffield research assistant in physics.

Congresses

International Conference on the Emission from the Aurora and the Night Sky

An international conference to discuss the emission from the aurora and the night sky is being arranged under the auspices of the Gassiot Committee of the Royal Society. This will be held in London during July 7–11 at the rooms of the Royal Society at Burlington House.

Conference on the Strength of Solids

A detailed programme has now been prepared of the Conference on the Strength of Solids to be held at the H. H. Wills Physical Laboratory, University of Bristol, during July 7–10 (see *Nature*, Feb. 8, p. 193). The topics to be discussed include hardening of metals by internal oxidation (J. L. Meyering, Eindhoven), rate of approach to the ordered state in alloys (M. Weil, Grenoble), mechanical properties of metals at low temperatures (Prof. M. J. Druyvesteyn, Delft), creep in metals (Prof. E. N. da C. Andrade, Dr. E. Orowan and Dr. B. Chalmers), recovery and recrystallization (Prof. W. G. Burgers, Delft), hardness and crystal size (Sir Lawrence Bragg), thermo-electric methods of studying diffusion (C. Crussard, Paris), internal friction in metals (Prof. L. Guillet, Paris), elastic after-effects in iron (Prof. H. B. G. Casimir, Eindhoven) and sintered artefacts (J. H. McKee).

Nuclear Physics in Biological and Medical Sciences

The University of California Medical School, in association with University Extension, University of California, has arranged a course in the application of nuclear physics to the biological and medical sciences. This course will be given at the Medical Center, San Francisco, during June 30–July 18. There will be lectures, laboratory demonstrations and seminars for round-table discussions. The course is open to those interested in the field of medical and biological research. The first week will be devoted to lectures, etc., on the general subject, the second week to the radioactive 'tracers' in biology and medicine and the third to therapeutic and diagnostic aspects of 'tracer' elements. Detailed information can be obtained from Dr. Stacy R. Mettier, head of the Post-graduate Instruction Medical Extension, University of California Medical Center, San Francisco 22, California.

Industrial Utilization of Agricultural Products and of Seaweed

A Colloquium on the Industrial Utilization of Agricultural Products and of Seaweed, arranged by the Irish Chemical Association and the Dublin Section of the Royal Institute of Chemistry, will be held in the Department of Chemistry, University College, Dublin, on July 2 and 3. The meetings will be opened by the Minister for Industry and Commerce of Eire, and the first session will be a general survey opened by Prof. J. L. Simonsen, director of the Colonial Products Research Council, London, who will speak on "Agricultural Products and the Chemical Industry". The second session, on seaweed, will be opened by Prof. J. B. Speakman, professor of textile industries, University of Leeds, with a paper on "The Production, Properties and Uses of Seaweed Rayon". The third session will deal with carbohydrates, and will be opened by a paper by Prof. E. L. Hirst, Sir Samuel Hall professor of chemistry, University of Manchester, on "The Utilization of Carbohydrate Products". On July 3, there will be a Government reception at Phœnix Park, Dublin.

Announcements

Sir Robert Robinson, Waynflete professor of chemistry in the University of Oxford, and Prof. P. Karrer, professor of chemistry in the University of Zurich, have been elected *Correspondants* for the Section of Chemistry of the Paris Academy of Sciences. Sir Robert Robinson has also recently been elected a foreign member of the Royal Norwegian Academy of Sciences.

A conversazione of the Royal Society is being held at the Society's rooms on May 29 at 8.30 p.m.

Mr. J. Davidson Pratt, director and secretary of the Association of British Chemical Manufacturers, has been awarded by the American Government the Medal of Freedom with silver palms for exceptionally meritorious work and co-operation with the United States while Controller of Chemical Defence Development at the Ministry of Supply during 1940–45.

The Ministry of Supply announces the following appointments to the Minister's Advisory Council on Scientific Research and Technical Development: Prof. Wesley Austin, Goldsmith's professor of metallurgy in the University of Cambridge; Prof. W. E. Curtis, professor of physics at King's College, Newcastle; Lord Hankey; Prof. Willis Jackson, professor of electrical engineering at the Imperial College of Science and Technology, London; Prof. E. K. Rideal, Fullerian professor of chemistry at the Royal Institution; Mr. S. Robson, of the Imperial Smelting Corporation of Bristol.

Dr. E. C. Amoroso, reader in histology and embryology at the Royal Veterinary College, London, has been appointed to the chair of veterinary physiology in the College.

Erratum. In the communication "Phase-Contrast in the Photomicrography of Metals", in *Nature*, May 10, p. 639, par. 6, for "42-mm. oil immersion" read "2-mm. oil immersion".

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications

Discovery of a New Skull of the South African Ape-man, *Plesianthropus*

BETWEEN 1924, when the Taungs ape-man was discovered, and 1941, when the jaws of the baby Kromdraai ape-man were found, remains of many individuals of this wonderful family, which some of us consider to be nearly related to man, were discovered; sufficient to show that in South Africa we may have the key which will solve the problem of the origin of man. But from 1941 until a few months ago, no further research was undertaken.

In 1946, a book was published on all we know of the South African ape-man; and the world awoke to the possibilities of the wonderful results that might be achieved by the further study of our caves. The United States has come to realize that South Africa is a more promising centre for the solution of the problem than even Java or China; and she seems determined to see that the problem must be solved, and solved soon.

At the beginning of this year, at the special request of General Smuts, I again started to hunt for more 'missing links'. My assistants and I commenced work at Kromdraai and continued there for three months. We found many interesting remains, including a very fine skull of a sabre-tooth tiger (*Megantereon*) and the skull of a large type of 'baboon', which belongs to a new genus; but only one bone that had possibly belonged to an ape-man.

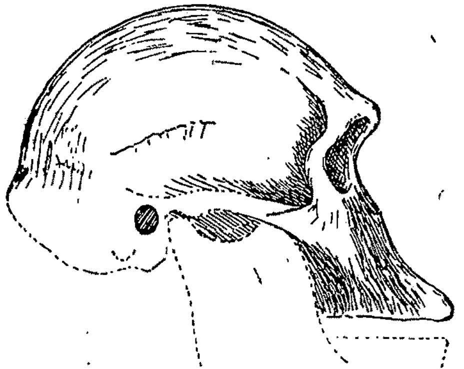

Fig. 1. SIDE VIEW OF SKULL OF OLD FEMALE STERKFONTEIN APE-MAN *Plesianthropus transvaalensis* (BROOM). ⅓ NATURAL SIZE. THE LOWER PART OF THE OCCIPUT AND PART OF THE JUGAL ARCH ARE STILL EMBEDDED IN MATRIX, AND THE LOWER JAW IS NOT PRESENT

Then on April 1 we started work at Sterkfontein, and almost immediately our labours were rewarded by sensational discoveries. On April 8 we found an isolated crushed snout of an adolescent *Plesianthropus* with some beautiful teeth; and a fragment of a snout of a child of possibly three years. This showed the perfect upper milk molars, and a note on the discovery was sent to *Nature* [see issue of May 3, p. 602. Editors]. On April 11 two quite isolated teeth of Sterkfontein apes were found—one the beautiful upper canine of a male of perhaps thirty years, and a lower mol probably of a female of forty years.

But on April 18 a small blast cracked open a blo of breccia, and there in the middle lay a perfect sk without the mandible of an adult *Plesianthrop* with the brain case broken across. In ten days had found the remains of five—possibly six individuals of the Sterkfontein ape-man, *Plesia thropus*, and one of them represented by a comple skull.

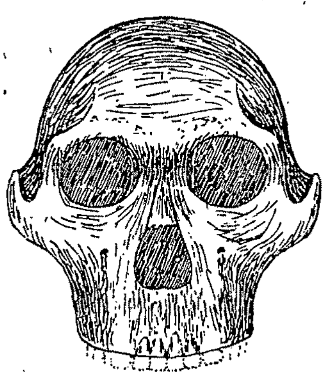

Fig. 2. FRONT VIEW OF SKULL OF OLD FEMALE STERKFONTEIN APE-MAN, *Plesianthropus transvaalensis* (BROOM). ⅓ NATURAL SIZE

The bones are very friable and the matrix not on rather hard lime, but also breccia with many lar broken pieces of chert; it will take many wee before the skull can be completely developed fro the matrix.

Enough, however, has now been done to reve most of the more striking features of the skull. the type skull the brain cavity was filled wi matrix. In the newly discovered skull there only a lining of lime crystals from about ⅛ in. nearly ½ in. in thickness. When this layer is remov we will have every detail of the anatomy of the inn side of the base of the skull. The under surface the base of the skull appears to be just as perfec but it will take some further weeks of preparati to reveal it all.

So far, our labours have been concentrated on t details of the face, and in cleaning the cranial vau The teeth are all lost, but many sockets rema and we can say with much confidence that the sk is that of an elderly female.

The drawings I give will serve to show the gener aspect of the face and the side view. I think the will be very general agreement that the being is n a chimpanzee or even closely allied to any of t living anthropoids, and that, though small, the sk has many resemblances to that of man.

The skull from glabella to opisthocranion is abo 150 mm., and the greatest parietal width is abo 100 mm. It is thus seen to have an index of abo 66, and to be extremely dolichocephalic. As ye we can only give a roughly approximate size for t brain cavity, but it seems probable that it will about 500 c.c.

Of course, it will take many weeks before the sk is completely worked up and a full account can published, but it seems well that the world shou know that such a valuable skull has been discover

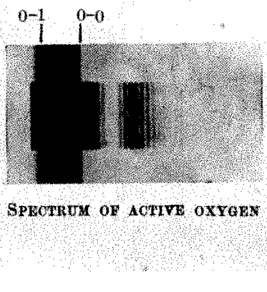
Active Oxygen

THE light of the night sky has excited increased attention since the end of the War; from the practically minded student of rockets and from astronomers, as well as from students of the upper atmosphere. The astronomer is particularly interested because of the effect of this radiation on his observations. To the student of the upper atmosphere, this radiation has held out a promise of information concerning the composition of the upper air, as well as concerning fundamental processes there. Because of the difficult problem presented by spectroscopy of the light of the night sky, there are still many unidentified radiations in its spectrum, as well as inadequately studied regions. In every review of the contributions of spectroscopy to the study of the upper atmosphere, attention is directed to the desirability of further laboratory investigations of the spectra of O_2 and N_2, and the desirability of obtaining emission spectra of ozone and the oxides of nitrogen. It has been suggested that a search along these lines may yield a satisfactory identification of the strong ultra-violet band at λ3556 A.

These facts, and some recent observations by Stebbins, Whitford and Swings[1] at Mt. Wilson on one hand, and by R. Herman, L. Herman and J. Gauzit[2] at the Lyons Observatory on the infra-red spectrum of the night sky on the other, led me to an extended study of the auroral afterglow in the infra-red. A particularly good nitrogen auroral afterglow at very low pressures was studied, and in time the intensity of the afterglow went down considerably, because of the decrease in pressure which resulted from the clean-up of the nitrogen. It was found that under these conditions the addition of relatively small quantities of oxygen restored the intensity of the afterglow in a very effective manner. This suggested that increasing the amount of oxygen might lead to interesting results, and this was done. It should be mentioned first that the neutral oxygen molecule does not readily show an emission spectrum. A part of the main absorption system observed by Schumann has been observed in emission by Runge, and hence the name Schumann–Runge bands for these famous ultra-violet bands. Hopfield reported an emission spectrum in the region below λ 2218 A. consisting of a single progression. Other band systems, much too few in number and all consisting of transitions from the ground state to low-lying metastable states, have been observed in absorption in gaseous and liquid oxygen. The most famous of these are the so-called atmospheric bands, $A^1\Sigma \leftarrow X^3\Sigma$, observed in atmospheric absorption (especially the solar spectrum), and also observed in the laboratory by absorption through pure oxygen. It is this system which has now been observed for the first time in emission in the afterglow in oxygen, which resulted from the above procedure.

The name 'active oxygen' will be used to identify this phenomenon, just as the name 'active nitrogen' was given to the similar phenomenon in nitrogen.



SPECTRUM OF ACTIVE OXYGEN

The spectrum of the afterglow of active oxygen which is reproduced shows two members of the atmospheric system of oxygen, which are readily identified as 0–0 and 0–1 by comparing them with the first positive system of nitrogen which is superposed. Using hypersensitized Eastman *IN* plates, it is easy to obtain a good spectrogram in a time equal to that necessary for the nitrogen afterglow. It is quite likely that further studies of this afterglow will aid in the study of the physics of the upper atmosphere.

Structure of 'Terylene'

ARISING from the recent communication by Prof. W. T. Astbury and Mr. C. J. Brown[1] concerning the structure of 'Terylene', we wish to place on record the earliest investigation of its structure by the X-ray method. The results recently reported by Astbury and Brown from work done in 1944 are in general agreement with those which we obtained some two years earlier.

Early in 1942, the Controller of Chemical Research, Ministry of Supply, learned of the work of Mr. J. R. Whinfield and Dr. J. T. Dickson (of the Calico Printers' Association, Ltd.) on polyethylene terephthalate[2], and requested the Chemical Research Laboratory, D.S.I.R., to assist in its further development. As a result, almost the first step taken was to arrange for the National Physical Laboratory to carry out an X-ray examination of various 'Terylene' samples supplied by Mr. Whinfield and Dr. Dickson; this work was completed by July 7, 1942.

The granular powder produced by cooling a nitrobenzene solution of 'Terylene' gave the pattern shown in Fig. 1. The well-defined system of rings, corresponding to lattice-spacings of 10·5, 5·4, 5·0, 4·1, 3·9 and 3·4 × 10^{-8} cm., indicates that the material is definitely crystalline in the sense that neighbouring molecular chains bear a regular spatial relation to each other.

Slow cooling of molten 'Terylene' produces an opaque material which gave the pattern shown in Fig. 2. This is identical with Fig. 1, though the rings are somewhat sharper. The material has therefore the same structure, and the greater sharpness may be due to a larger particle size.

When molten 'Terylene' is shock-cooled, a translucent product is obtained; this gave the pattern shown in Fig. 3, which contains two diffuse haloes. The inner halo corresponds to the inner ring (spacing 10·5 A.) of the previous forms. The outer halo corresponds to the outer group of diffraction rings of the previous forms; the rings have diffused together to form a broad halo. The molecular structure is therefore a heavily distorted form of the regular structure shown by the previously described crystalline forms.

Shock-cooled filaments may be cold-drawn into 'Terylene' fibres, and these gave the pattern shown in Fig. 4. This shows that very pronounced orientation of the molecules along the length of the fibre has taken place, the orientation being complete to within about 5°. The orientation is indicated by the con-

Fig. 1

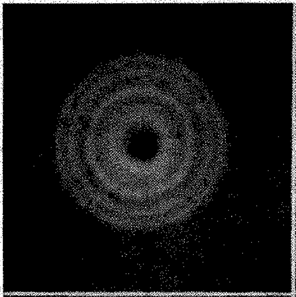

Fig. 2

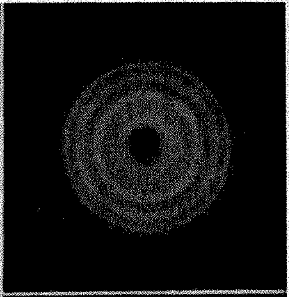

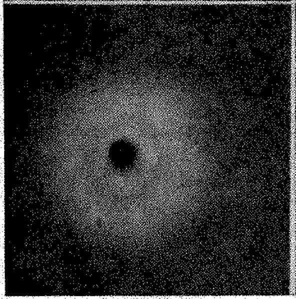

Fig. 3

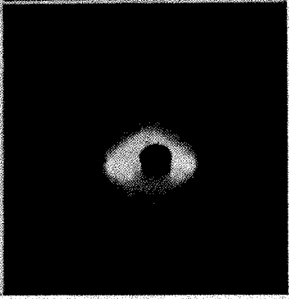

Fig. 4

centration of the intensity of the rings to a few points on the circumference. The diameters of the rings, on which the intensity maxima are formed, are the same as the diameters in the previous crystalline forms, indicating that the basic molecular structure is the same. It will be seen that the maxima are not so sharp as the rings shown, for example, in Fig. 2; in aligning the molecules along the length in cold-drawing, some of the distortion marking the shock-cooled material is retained.

This note is published by permission of the Chief Scientist, Ministry of Supply, and of the directors of the Chemical Research and National Physical Laboratories.

Electrical Conductivity of River, Rain and Snow Water

"THE DATA OF GEOCHEMISTRY", by the late F. W. Clarke, is a mine of information on river waters, their variation with geological formation and Joly's 'cyclic sodium' transported in the air and brought down by rain. These phenomena are simply studied by measurements of electrical conductivity at 0° C. Thus $C \times 10^6$ for Plymouth tap-water varied during 1923–24 from 25 to 28; the values found on July 7, 1923, and September 26, 1923, were 27 and 28—identical respectively with those of July 5, 1945, and September 19, 1945. The *p*H varied from 6·4 to 6·8 during the year. It was with some surprise that I found rain-water, collected at Downderry on the Cornish coast during a downpour on March 12, 1946, to have a conductivity 24, with *p*H 6·6. Rain at Plymouth on March 13, 1946, had conductivity 55 and *p*H 4·0. During the night of September 19–20, 1946, rain at Antony, Cornwall, had conductivity 28, the typical September figure for Dartmoor water. Clean snow at Downderry on January 24, 1947, gave 44, and a Plymouth sample of January 25, 1947, gave 72 for conductivity. The latter was taken from the middle of the snow blanket and was, on thawing, surprisingly sooty. Plymouth rain of January 8, 1947, had conductivity 70, close to that of snow.

The country rain samples, with conductivities 24 and 28, had come with south-westerly air, clean from the sea. Thus Dartmoor water derives almost all its electrolytes from sea-salt, but contains from 3·1 to 3·5 parts per million of silica, and colouring matter equivalent to 0·26–0·40 p.p.m. of the yellowish tint given in the silica reaction. The conductivity of water from a calcareous source is about ten times as great. On diluting sea water with 'conductivity water' of conductivity 1 or less, a curve was obtained relating dilution to conductivity and showing that country rain represents sea water diluted to rather less than 1 in 2,000. The purest British natural water met with was the Aberystwyth town supply, conductivity 19.

Early in July 1945, however, samples of river water were flown to Britain from Ceylon. These were astonishingly pure and gave conductivities 10–20. The error due to solubility of the glass appeared to be negligible, and the purest sample corresponded to sea water diluted slightly less than 1 in 5,000. Since the sea water from the English Channel had salinity $35{\cdot}2\,^{0}/_{00}$, or chlorine $19{\cdot}4\,^{0}/_{00}$, the purest sample, with conductivity 10, contained 3·9 parts per million chloride. The amounts may seem small; but it should be remembered that phosphate in natural waters is reckoned in parts per hundred or per thousand million, and upon these traces the production of all water-living organisms depends.

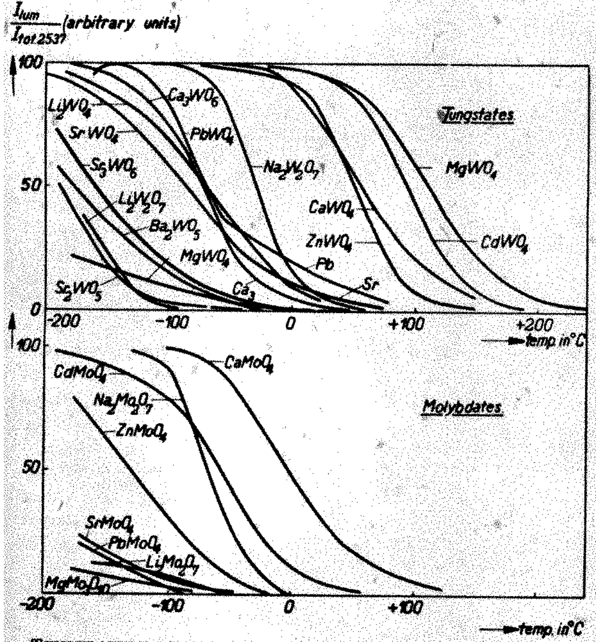
Fluorescence of Tungstates and Molybdates

THE tungstates of calcium, strontium, magnesium and zinc, and the molybdates of calcium are known to show luminescence upon excitation by cathode rays or short-wave ultra-violet radiation. It is commonly assumed that this luminescence is characteristic of the tungstate and molybdate groups. If this is true, there must be a reason why other tungstates and molybdates are found to be non-luminescent. Studying a number of different tungstates and molybdates in this Laboratory, we have found this reason to be the temperature-quenching.

Tungstates and molybdates of zinc, magnesium, cadmium, calcium, strontium, barium, lead, lithium and sodium have been prepared by the following method. Oxides or carbonates of the elements mentioned were mixed in stoichiometric proportion with tungstic or molybdic acid and a little water. The mixture was dried on a water bath and fired at temperatures below the melting point of the particular system, but high enough to guarantee good crystallization. These temperatures varied between 530° for lithium molybdate to 1,100° for most of the tungstates. One sample of magnesium tungstate was heated to a higher temperature (1,300° C.) in order to obtain the high-temperature α-form[1].



TEMPERATURE-DEPENDENCE OF THE FLUORESCENCE OF TUNGSTATES AND MOLYBDATES FOR EXCITATION BY λ 2537 A. (MAXIMA ARBITRARILY FIXED AT 100-LEVEL). (THE MODIFICATION OF MAGNESIUM TUNGSTATE THAT IS QUENCHED AT LOW TEMPERATURES IS THE α-FORM)

Nearly all substances investigated show fluorescence at a low temperature upon excitation by λ 2537 A. (see graph). The temperature-range in which quenching occurs is different, not only for compounds of different composition, but also for the same compound in different modifications (α- and β-magnesium tungstate). For the few tungstates for which no luminescence was found, the quenching range is probably situated beyond −180° C., so that fluorescence may be expected at extremely low temperatures. The quenching-ranges of tungstates are, on the whole, at higher temperatures than those of the molybdates. This explains why many more tungstates than molybdates are known to show luminescence.

A more complete report of our investigations, including measurements of absorption and fluorescence spectra, is to be published elsewhere[2].

Gas Discharge in Air of Atmospheric Pressure at Very Low Voltage

IT has been observed that a potential difference of as little as 15 V. applied between two semi-conductors in contact with each other, or alternatively, of a semi-conductor in contact with a metal, may sustain a gas discharge in air of atmospheric pressure.

The semi-conductors used were grains of pale green carborundum, selected for paleness from commercial No. 8 mesh samples. The grains were either stuck with solder into metal holders, or laid on a hardened and polished steel block and a second similar block laid on top of the grain. The potential was taken from the sliding contact of a low-impedance potentiometer across D.C. mains and measured by means of an ordinary voltmeter.

The gas discharge was of a pale bluish-mauve colour, and if viewed through a low-power microscope was seen to consist of streamers from grain to grain (or grain to steel block) near the point of contact. The streamers were several microns long.

The phenomenon could not be observed in every case. The potential range at which it would occur is from less than 15 V., but more than 13 V. to about 50 V. At higher potentials the contact area would as likely as not become incandescent and, therefore, so highly conductive that equipotential surfaces in the crystal would move outwards, bringing the areas of the crystal where the potential difference across the gap reaches 15 V. into regions where the air-gap becomes too wide.

A phenomenon like this was expected to occur only in the immediate neighbourhood of the contact, that is, where the air-gap was comparable with the mean free path of gas molecules. Where in fact it occurs, the path along the streamer contains many hundred mean free paths, and it is therefore believed that radiation from streamer to streamer plays an essential part in the excitation mechanism.

Bay and Szigeti[1] described luminous phenomena on carborundum crystals. Similar phenomena were also observed by me. They are apparently due to incandescence at the point of contact and occur if the current is allowed to build up to values in excess of those at which gas discharges can occur. Light travelling from the incandescent zone inside the crystal emerges from its whole surface and gives the appearance of the whole crystal being luminous. As the light is due to the incandescence of a substance which disintegrates below 2,000° K., and which radiates rather like a black body, it is originally of a yellow tinge. After transmission through a more or less coloured crystal, it emerges filtered sometimes as a pure white and sometimes as a brilliant yellow. The bluish-mauve colour of the gas-discharge described above has never been observed to emerge from the mass of the crystal. There is also no low-voltage limit for sustaining this mass glow once it has been initiated.

My observations are now some years old. Pressure of other work has since, and will presumably in the future, prevent my following the matter up further.

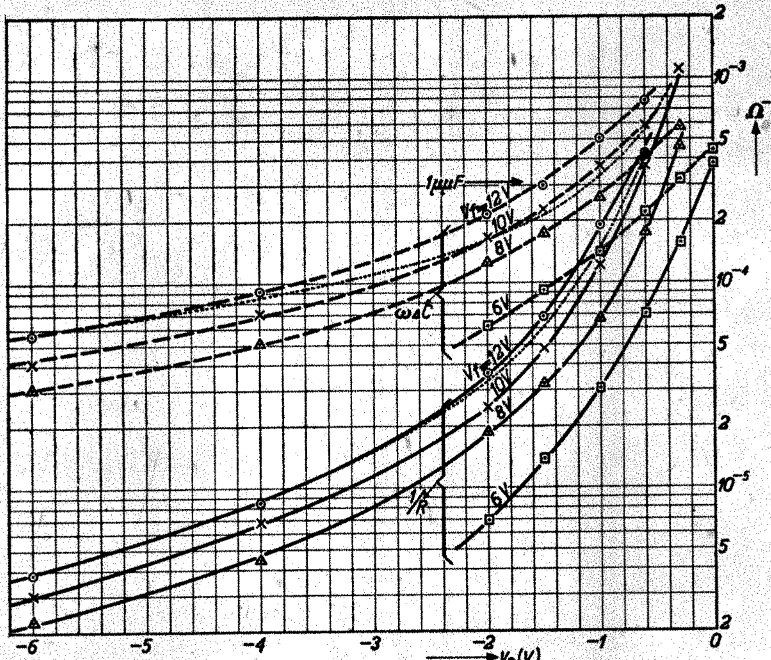
Total Emission Damping in Diodes

A FEW months ago, C. N. Smyth[1] published preliminary results on a new source of energy loss in space-charge-limited diodes at high frequencies. This energy loss was due to the space-charge between the electrodes, and hence it was called 'total emission damping'; it is a transit time effect occurring at ultra-high frequencies only. The same effect was observed a few years ago at this Laboratory at about 100 Mc. After reading Mr. Smyth's communication we took up this subject again.

We carried out measurements at 5·8 m. wavelength on a diode having an emitting cathode area



1/*R* AND $\omega\Delta C$ AS A FUNCTION OF V_a FOR HEATER VOLTAGES V_f OF 12 V., 10 V., 8 V. AND 6 V. RESPECTIVELY

of about 10 cm.^{2} and an anode–cathode distance of 0·1 cm. The results are shown in the accompanying graph, in which the conductive part $1/R$ (full lines) and the reactive part $\omega\Delta C$ (broken lines) of the additional admittance due to the space-charge between anode and cathode is plotted against the anode voltage V_a (not corrected for contact potentials) with the heater voltage V_f as a parameter (heater voltage V_f = 12 V., 10 V., 8 V. and 6 V. respectively).

The graph also shows the dotted curves $C_1 V_a^{-1}$ (upper curve) and $C_2 V_a^{-2}$; the constant C_1 is chosen so that the first curve coincides with the curve $\omega\Delta C$ (for V_f = 12 V.) at $V_a = -6$ V., the constant C_2 so that the second curve coincides with the curve $1/R$ (for V_f = 12 V.) at $V_a = -6$ V. These curves indicate that $\omega\Delta C$ and $1/R$ are approximately proportional to V_a^{-1} and V_a^{-2}, respectively. $\omega\Delta C$ and $1/R$ are only slightly dependent upon the saturation current of the cathode. Taking the saturation current at V_f=6 V. as a unit, we measured at V_f=8 V., 10 V. and 12 V., saturation currents of 14, 140 and 1,100 units, respectively. This shows that a change in saturation current by a factor 100 only results in a change in $\omega\Delta C$ and $1/R$ by about a factor 3 or less. It would be expected from a theoretical point of view that the dependence of $\omega\Delta C$ and $1/R$ upon the saturation current will be more pronounced if either the cathode–anode distance or the saturation current is smaller (compare the curves for V_f = 6 V. and V_f = 8 V.).

It is also to be expected from a theoretical point of view that ΔC would scarcely depend on frequency, and that $1/R$ would be proportional to ω^2, except for the highest frequencies.

A full account of our investigations will be published elsewhere.

Determination of the 'Loading' in Paper by Microradiography

THE development of microradiography as a result of the researches of Goby, Dauvillier, Lamarque, Trillat, and of Maddigan, Ball, Clark, etc., is well known. The latter recommended the use of characteristic radiation for metallurgical applications. One may endeavour to generalize his ideas in other fields.

In this respect, we have been able to show that it is possible to obtain information regarding the 'loading' in paper by using a characteristic radiation (iron $K\alpha$, or copper $K\alpha$).

The 'Metalix' tube used is run at a tension of 25 kilovolts. The samples are placed in a circular camera at 2 cm. from the window. The emulsion is a Lippmann-Gevaert film placed in direct contact with the sheet to be examined. For an intensity of 15 milliamperes, the time of the exposures did not exceed five minutes. After development, the image was enlarged by a microscope with a photographic camera.

Figs. 1 and 2 correspond to bisulphite papers with 'loadings' of different natures amounting to 10 per cent. The 'loading' appears in white, and the initial enlargement is of a range of 125 diameters. A comparison between the photographs shows the interest of the method.

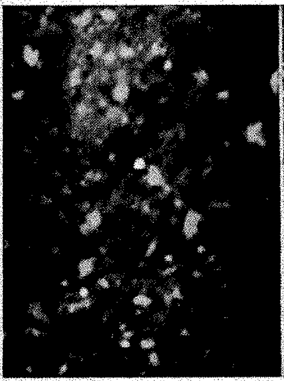

Fig. 1

Fig. 2

We have taken microradiographs of many samples of paper 'loaded' with different materials (titanium oxide, kaolin, etc.) at different concentrations. With characteristic radiation it is possible to control the loading in paper and even to determine approximately its proportion[1]. In order to obtain information regarding the actual fibres, it is necessary to use a greater wave-length (for example, chromium $K\alpha$) or a low-voltage tungsten tube.

The above investigation was carried out for the Fonds du Centenaire de l'A.I.Lg.

Equivalence of Mass and Energy

THE following describes an ideal experiment from which the law of equivalence of mass and energy may be derived by using means employed in elementary physics.

Suppose a cylindrical tube entirely evacuated at the ends of which mirrors μ_1 and μ_2 are placed perpendicular to the generating line of the cylinder, and let the coefficient of absorption of μ_1 and μ_2 be zero. A ray of light perpendicular to the mirrors will be therefore reflected from μ_1 and μ_2 for an indefinitely long time.

Consider a monochromatic ray composed of photons, the mass of each photon being m and the velocity of each being c (in vacuum). The impulse of each photon is therefore equal to mc, and after reflexion it reverses its direction only, if we assume that photons have absolute elasticity (an assumption made, for example, in the Compton effect).

Applying the method used in the elementary kinetic theory of gases, we get

$$p = 2mc \, . \, N \, . \, \frac{c}{2a} \, . \, \frac{1}{S},$$

where p signifies the mean pressure of a bundle of parallel rays on one of the mirrors, N is the total number of photons in the tube, a is the length of the tube, and S is its area of cross-section.

Substituting the volume V for aS,

$$pV = mc^2N.$$

An infinitesimal parallel displacement of one mirror towards the other will diminish the volume of the tube by dV. The amount of work done by this displacement is pdV. Evidently, this amount is equal to the energy increase of the 'photonic gas', or of all its N photons together.

Differentiation of the preceding formula gives

$$p \, . \, dV = c^2N \, . \, dm,$$

since the number of photons does not change and the velocity c (according to a postulate of the theory of relativity) remains unchanged too.

Indicating by dE the energy increase of each photon, we get

$$\frac{p\,dV}{N} = dE = c^2dm.$$

Moving the mirrors towards each other by a finite distance and integrating, we get

$$E - E_0 = c^2(m - m_0);$$

or

$$E - mc^2 = E_0 - m_0c^2 = \text{constant},$$

for any pair of values of E and m.

Hence

$$E = mc^2 + \text{constant}.$$

Since an expression of energy leaves an additive constant free, we may so choose the latter that

$$E = mc^2.$$

The above proof of this fundamental formula applies, of course, only to the special case of the energy of photons.

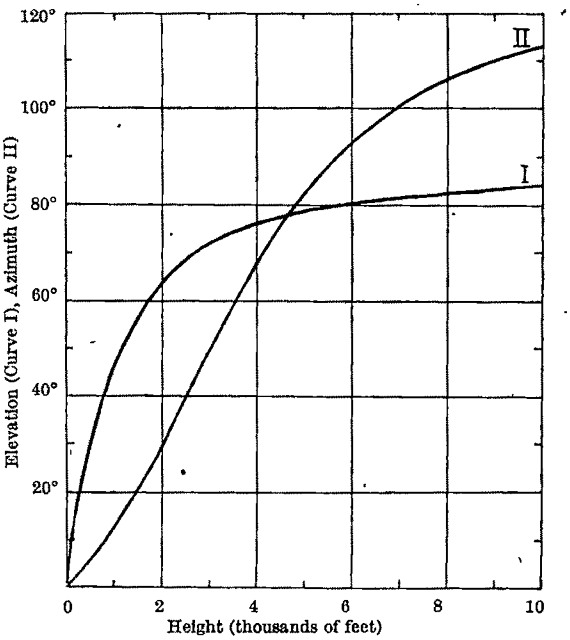
Haifa.

An Azimuthal Method of Measuring Cloud Height with a Searchlight

THE normal method of determining the height of the cloud base at night is to direct a vertical searchlight beam on to the cloud and measure the angle of elevation E of the spot of light from a point at a known horizontal distance L from the searchlight. The height h of the cloud base is then given by $h = L \tan E$. The length L of the base-line is normally about 1,000 ft.

The precision of the method clearly depends upon the accuracy with which the angle of elevation E can be measured. In practice, a limit to the observational accuracy is set by the fact that the spot of light is never sharply defined, because of the diffuse nature of the cloud surface. A reading to the nearest whole degree is therefore the best that can be expected.



CURVE I: VARIATION OF ELEVATION WITH HEIGHT OF CLOUD; VERTICAL BEAM; BASE-LINE, 1,000 FT. CURVE II: VARIATION OF AZIMUTH WITH HEIGHT OF CLOUD; SEARCHLIGHT AT 76°; BASE-LINE, 1,000 FT.; DIRECTION OF BEAM, 45° FROM DIRECTION OF BASE-LINE

Curve I shows the relationship between E and h for the case $L = 1{,}000$ ft. It will be seen that for heights exceeding 4,000 ft. the rate of increase of E with h is very small. The increase of elevation between $h = 5{,}000$ ft. and $h = 10{,}000$ ft. is, in fact, only 5·6°. As E can only be measured to the nearest degree, cloud heights in this range can therefore only be measured to about the nearest 1,000 ft. The new code for height of cloud adopted by the International Meteorological Committee at Paris in 1946 provides for reporting observations to the nearest 300 ft. in this range. It is necessary, therefore, to consider means of improving upon the accuracy obtainable by the present method.

If the searchlight beam is tilted out of the vertical in a direction transverse to the line of sight, both the azimuth and elevation of the spot of light will vary with the height of the cloud. It is possible, therefore, to make use of the variation of azimuth to determine the height of the cloud. If α is the angle of inclination of the beam to the horizontal plane, β is the angle of orientation of the beam and θ is the azimuth of the spot of light (β and θ both being measured from the direction of the base line as zero), it is readily shown that

$$h = L \tan \alpha \,.\, \sin \theta \,.\, \operatorname{cosec} (\beta + \theta).$$

It is found that by choosing suitable values for L, α and β, one obtains a relationship between h and θ which is very much more satisfactory for measuring heights exceeding about 2,000 ft. than is possible by using the angle of elevation with a vertical beam. Curve II has been drawn for the case $L = 1{,}000$ ft., $\alpha = 76°$, $\beta = 45°$. It will be seen that for heights above 2,000 ft. Curve II is everywhere substantially steeper than Curve I. In particular, the change of θ between $h = 5{,}000$ ft. and $h = 10{,}000$ ft. is 31°, as compared with a change of 5·6° in E for the same difference of height. The values of α and β used for drawing Curve II are not necessarily the optimum values or those which will be adopted after trials of the method have been carried out.

For heights below about 2,000 ft. the rate of change of elevation with height is very rapid, and is, in fact, rather more rapid with a tilted beam oriented at 45° to the direction of the base line than with a vertical beam. It is concluded, therefore, that the best method of applying the searchlight method is to use the inclined beam system here described, making measurements of elevation for heights up to 2,000 ft., and of azimuth for greater heights.

A fuller discussion of the method will be published elsewhere. I have to thank the Director of the Meteorological Office for giving me permission to publish this preliminary note.

Dunstable, Beds.
March 24.

Electrical Properties of Paint Films on Metals

As part of an investigation on the protective properties of paint films on metals immersed in sea water, a study is being made of the electrical characteristics of such films and their changes with time.

The first approach consisted in following the electrode potential of painted mild steel plates immersed in an artificial sea water, on the lines adopted by earlier workers[1,2], but extending the period of test to cover the various stages of breakdown of the paint film. Plates were abraded, degreased and painted with two coats of an anti-corrosive marine paint, and completely immersed vertically, with provision for an electrical lead shielded from contact with the sea water. The results obtained for several paint systems show that there is a characteristic fall in potential during the first few hours (not well shown on the scale of Fig. 1); after an intervening period of somewhat fluctuating potential, there is a rise to a maximum with a final decline (Curve B, Fig. 1). The incidence of this final decline coincides with the time at which rusting begins to spread rapidly (cf. Curve A, Fig. 1).

The apparent ohmic resistance and the apparent capacity of the paint film were next investigated, using a Wheatstone bridge with a variable non-inductive resistance in parallel with a variable condenser in one arm of the bridge, in order to balance the resistance and capacity of the cell consisting of two similarly painted plates. Measurements have so far been made only at a frequency of 1,000 cycles per second. The results suggest that the resistance and capacity, especially the latter, are much more sensitive to breakdown of the paint film than is the electrode potential. The onset of rusting is indicated by a sudden large increase in capacity (Fig. 2) and a marked fall in resistance (Fig. 1, Curve D). The curves in Fig. 2 (drawn on a larger scale than Fig. 1) show the large capacity changes due to the initial breakdown of paint films consisting respectively of one, two, or three coats.

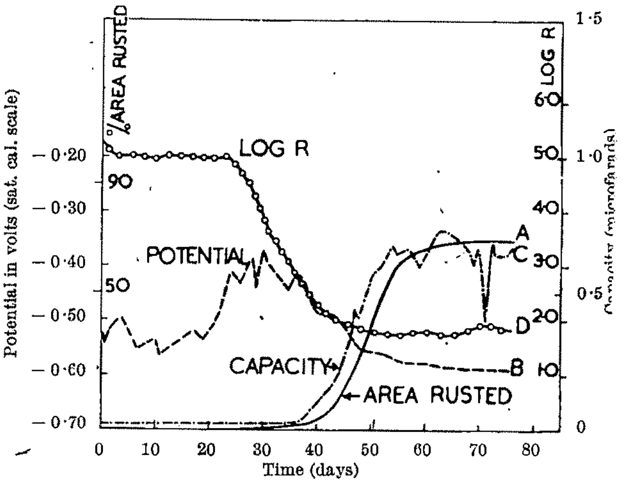

Fig. 1. Relationship between area rusted and changes in electrical properties of paint films on steel

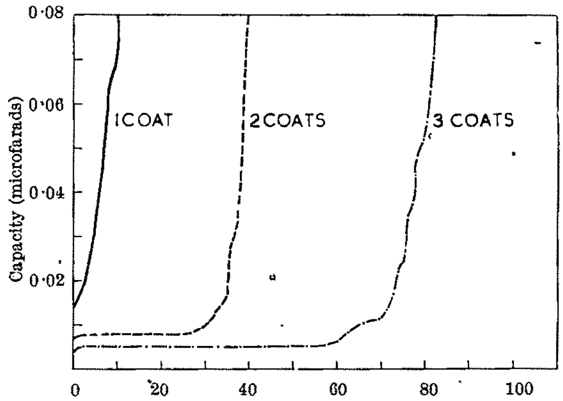

Fig. 2

The general correlation of the changes in all the electrical properties (potential, resistance and capacity) with the gradual spread of rusting over a period of 76 days may be seen from Fig. 1. The figures for rusting represent approximate areas covered by rust; the true corroded area is appreciably less, but this can be estimated only after stopping the test and removing the paint and rust. Curve A (Fig. 1) does, however, fairly indicate the rate of spread of rusting, and it can therefore be used as a criterion for interpreting the changes in electrical properties of the paint film.

The values for capacity and resistance given in the graphs are the equivalent parallel capacity and the equivalent parallel resistance, as measured directly. The precise interpretation of these results needs further consideration and will be dealt with in a subsequent communication. It is evident, however, that the conception of the paint film as a 'leaking condenser' must provide the general explanation of the phenomena observed.

It is suggested that the technique should prove valuable as a sensitive means of following quantitatively the breakdown of paint films on metals exposed to aqueous solutions. The method has possible alternative applications to the study of other types of protective coatings and of thin films produced by corrosion inhibitors.

Analgesic Activity in Compounds Related to Amidone

AMIDONE (*dl*-2-dimethylamino-4 : 4-diphenylheptan-5-one) or Hoechst 10820 was made and examined by the I.G. workers at Hoechst during the War. Short preliminary accounts of the properties of this compound have appeared in both the British and American literature, where the activities of some analogous compounds are also described[1,2,3].

As the series is so obviously interesting, we have prepared, in addition to amidone, some of its analogues by condensing diphenylacetonitrile with various aminoalkyl chlorides and treating the resulting basic nitriles with Grignard reagents. Details of some of these compounds are given in Table 1.

In general, the hydrochlorides were very soluble in water, whereas the other salts referred to in Table 1 crystallized readily from aqueous solution.

The analgesic, toxic and respiratory depressant actions have been compared by one of us (R. H. T.) with those of morphine, pethidine and a sample of the lævo form of amidone (*l*–820), obtained from Germany.

Analgesic action was estimated by the method described by Thorp[4], using groups of six rats with varied doses of the compounds compared with doses of 1 or 2 mgm./kgm. of morphine. Respiratory depression was measured in unanæsthetized rabbits after a single dose of the compound under test, the respiratory minute volume being recorded by the method of Gaddum[5]. The doses were adjusted to produce a steady depression of approximately 50 per cent of the normal resting level for at least one hour. The figures for toxicity are the approximate *L.D.*50 values for intravenous injection in mice. The pharmacological results are given in Table 2.

TABLE 2

Compound	Toxicity (mgm./kgm.)	Analgesic activity		Respiratory depressant activity	
		Equiactive doses (mgm./kgm.)	Approximate ratio	Equiactive doses (mgm./kgm.)	Approximate ratio
Morphine	—	2·0	(1·0)	5·0	(1·0)
Pethidine	60·0	15–20	0·15	30·0	0·15
l-820	10·0	1·0	2·0	1·5	3·3
70*C*47	35·0	30–40	0·05	No effect	—
10820	12·5	2·0	1·0	5·0	1·0
72*C*47	25·0	15–20*	0·1	Slight at 10·0	—
97*C*47	20·0	30–40*	0·05	No effect	—
133*C*47	12·0	30–40*	0·05	No effect	—
68*C*47	20·0	4–6	0·4	10·0	0·5
69*C*47	—	60*	0·03	No effect	—
67*C*47	20·0	40*	0·05	No effect	—

* In the case of these compounds, doses smaller than the equiactive dose were used in the test, the response obtained being similar to that for 1·0 mgm./kgm. of morphine.

No figure is given for the toxicity of morphine upon intravenous injection into mice, since these animals are not easily killed by morphine and the *L.D.*50 value (approximately 300 mgm./kgm.) does not correspond to that given by larger animals such as the rabbit.

With compounds having less than 1/10 of the analgesic activity of morphine and relatively high toxicity, the assessment of analgesia is not very reliable, since the doses approach the toxic level. With true analgesic drugs, a graded response is given with doses of 0·1 to 0·25 of the *L.D.*50 toxicity dose for mice.

The results show that, in compounds bearing the 2-dimethylaminopropyl group, analgesic action is optimal in the ethyl ketone 10820, but much less in the shorter- or longer-chain compounds. The radical alterations in the basic side-chain in compounds 68*C*47 and 133*C*47 result in decreased analgesic activity, but again the ethyl ketone is the more potent. Mice injected with compound 68*C*47 show complete narcosis with doses insufficient to cause

* Compounds tested pharmacologically, and to which the reference numbers apply.

respiratory arrest, whereas the latter symptom is the first to appear after large doses of amidone.

In animal experiments the respiratory depressant activity in these compounds parallels analgesic activity, so that, broadly speaking, in effective compounds a given degree of analgesia is accompanied by a similar degree of respiratory depression.

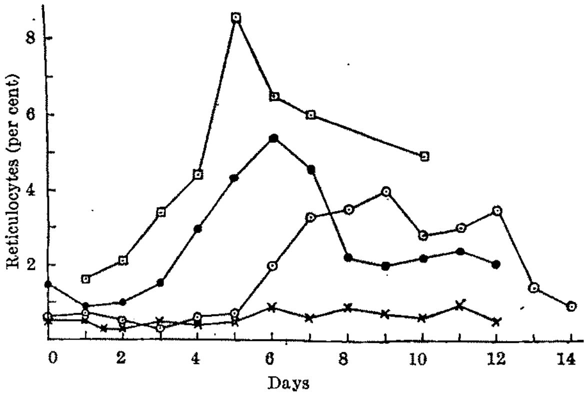
Thio-thymine (2-Thio-5-Methyl-Uracil)

SPIES *et al.*[1] have reported the value of 5-methyl-uracil (thymine) in the treatment of pernicious anæmia. Jacobson and Williams[2] have suggested the use of splenectomized rabbits for the assessment of anti-anæmic factors, and Bavin and Middleton[3] have shown that thymine causes a reticulocytosis when injected into such splenectomized rabbits. We have used a similar method for the study of the hæmopoietic activity of various thymine derivatives.

Di-hydro-thymine-4-carboxylic acid when injected intramuscularly into splenectomized rabbits in dosages of 100 mgm./kgm. does not cause a reticulocytic response, whereas 2-thio-5-methyl-uracil (in 100 mgm./kgm. dosage) and 2-amino-5-methyl-uracil (100 mgm./kgm.) do (see graph).



●, Thymine, 100 mgm./kgm. intramuscularly
○, Thio-thymine, 200 mgm./kgm. intramuscularly
×, Di-hydro-thymine-4-carboxylic acid, 100 mgm./kgm. intramuscularly
□, Amino-thymine, 100 carboxylic acid, 100 mgm./kgm. intramuscularly

The 2-thio-5-methyl-uracil compound (thio-thymine) is particularly interesting in that it contains the —NH.CS.NH— grouping which Astwood[4] has suggested is the common radical in many anti-thyroid compounds. We have found that when this compound is given by mouth to 21-day old female rats (Wistar) in a dosage of 40 mgm./100 gm. daily for ten days and the rats then sacrificed, the thyroids of these rats are grossly enlarged and hyperæmic. Histological examination of the glands revealed colloid loss, increased vascularity, and hyperplasia of the acinar epithelium. A dosage of 20 mgm./100 gm. daily by mouth for ten days did not cause any very marked thyroid changes.

Hence thio-thymine has both anti-thyroid properties and hæmopoietic activity. Moreover, the daily injection of 100 mgm./kgm. intramuscularly for ten days to splenectomized rabbits does not affect the white blood-cell counts of these animals. Again, the intramuscular injection of 20 mgm./kgm. daily (higher dosages caused death of some rabbits from pulmonary œdema) into normal rabbits for ten days produced, if anything, a polymorphonuclear leucocytosis (see table). Thio-thymine would seem, therefore, to be free from the depressant action on the bone marrow which has been noted in the use of thiourea[5] and thiouracil[6].

We are indebted to Mr. F. Fowler of Benger's Ltd. for preparing the above compounds.

Treatment of Myasthenia gravis with Di-isopropylfluorophosphonate

A NUMBER of papers have appeared recently dealing with di-isopropylfluorophosphonate, which was prepared by McCombie and Saunders[1] in 1941 and found by Adrian, Feldberg and Kilby[2] to cause a prolonged inhibition of cholinesterase. One of us (J. H. G.) tested its effect on myasthenia gravis in 1943, but had to abandon the work owing to lack of clinical material. This work was continued by the other, and the object of this letter is to report the results.

The drug was injected intramuscularly. In the earlier experiments it was freshly dissolved in water; later, the more stable solution in arachis oil was used. Serum cholinesterase was estimated manometrically using acetylcholine as substrate, and the strength of the muscles controlling the hand was measured with a dynamometer. Neostigmine (prostigmine) had its usual dramatic effects on all these patients. General weakness, ptosis, diplopia and dysphagia disappeared

Type of animal	Dosage of thio-thymine (mgm./kgm.)	White blood cell count in thousands on days										
		1	2	3	4	5	8	9	10	11	12	15
Normal rabbit	20	8·4	6·6	10·6	16·8	16·0	15·5	17·8	19·8	19·8	15·2	21·4
Splenectomized rabbit	100	10·8	12·0	9·6	8·1	7·7	11·3	12·9	13·0	12·7	8·7	10·3

The above figures are the average counts from three rabbits. Injections were given daily from day 3 to day 14.

within about half an hour and returned after two to three hours. The serum cholinesterase activity fell and the readings of the dynamometer rose; these changes occurred at about the same time as the clinical improvement. The injection of di-isopropylfluorophosphonate (0·1–10 mgm.) caused no obvious immediate clinical improvement, but the serum cholinesterase activity fell and the dynamometer readings rose within half an hour, and these changes lasted longer than the corresponding changes after neostigmine.

The absence of clinical improvement in spite of a marked fall in serum cholinesterase in these experiments was interesting but disappointing. It was, however, noticed that dynamometer readings taken at 10 a.m. showed a small rise lasting a number of days after injections of the drug. Experiments were therefore undertaken to test the effect of a daily dose. In three patients, 0·5–2 mgm. was injected once daily for periods up to three months. Neostigmine was also given in the early stages of this treatment. In two cases there was marked clinical improvement after one to two weeks of this treatment, and the daily requirements of neostigmine fell. The dynamometer readings taken 24 hours after the injections showed a marked rise, and the serum cholinesterase was reduced by 86–90 per cent. These patients were eventually discharged from hospital and continued to give themselves 0·5 mgm. per day, and have reported satisfactory progress so far. Atropine was given to counteract the muscarine actions of the di-isopropylfluorophosphonate; but in spite of this, all three patients complained of tightness of the chest, and in one case treatment was abandoned because of this effect.

These results are in general agreement with those of Comroe *et al.*[3].

Effect of Calciferol and of Penicillin on Experimental Tuberculosis of Guinea Pigs

Among the many points touched upon in recent literature of tuberculosis are: (1) the favourable results in the treatment of lupus, and possibly other forms of surgical tuberculosis, with calciferol[1-3]; (2) the conflicting results reported by various workers[4-6] as to the effect of penicillin. In the course of an extensive experimental study of the chemotherapy of tuberculosis, we have made observations bearing upon these questions which it is thought are of sufficient interest to report briefly.

500-gm. guinea pigs were infected with 0·001 mgm. of human tubercle bacilli (strain *H*.418) intramuscularly, and after four weeks, when all pigs were tuberculin positive, various treatments were commenced and continued for ten weeks. Survivors of all treated groups and of untreated controls were killed and assessed for infection by the method of Sher and Kloeck[7]. Individual and average assessments are given in the accompanying table; survival times were also noted. Streptomycin was taken as an active drug control, but only five animals were killed when this experiment terminated, as previous work had shown that the amount of drug given was enough to suppress the disease during the period of treatment (ten weeks).

Details of drug dosage are as follows:

Penicillin: 500 u. / guinea pig / day subcutaneously in saline given in two doses of 200 and 300 units a.m. and p.m.

Calciferol: 2,000 u. / guinea pig / day in arachis oil given with the food.

Streptomycin: 10,000 u. / guinea pig / day subcutaneously in saline given in two doses of 4,000 and 6,000 units a.m. and p.m.

Group	Deaths	T.B. assessments	Average
Untreated (14)	5/14	71*, 74, 53, 85*, 51 88, 85, 49, 88*, 81* 65, 81,* 84, 85	74·3
Penicillin (11)	8/11	75*, 73*, 71*, 73, 83* 61, 86, 88, 82*, 65* 79*	75·5
Calciferol (12)	5/12	88*, 78*, 69, 98*, 66 68, 76*, 86*, 62, 79 71, 71	76·0
Streptomycin (50)	0/50	5 killed at random 4, 2, 4, 2, 2	2·8

* Asterisk denotes death of animal

It is obvious from the results that there is no difference between the extent of tuberculosis of penicillin-treated, calciferol-treated and control groups.

There was no evidence of toxicity or abnormal calcification in the animal treated with calciferol, nor in a group of normal guinea pigs which received 25,000 units of calciferol a day for ten weeks. These doses roughly correspond to those used in the treatment of lupus vulgaris in man.

I wish to thank Sir Jack Drummond, who suggested the work on calciferol, Mr. C. E. Coulthard, for his interest in these investigations, and Mr. B. H. Chantrill, for help with the *in vivo* work.

Fibrinolysis in the Animal Organism

It is now known that the action of the fibrinolytic substance produced by certain streptococci is due to its properties as an activator for the transformation of a proenzyme present in blood serum and plasma into a proteolytic enzyme acting on the fibrin. This activation can also be carried out by treatment with chloroform (for references see Christensen[1] and Kaplan[2]). Considerable confusion concerning the nomenclature for the substances interacting in the fibrinolysis exists; but it seems most logical to use the proposal of Loomis, George and Ryder[3]. According to this, the name 'fibrinolysin' is used for the active fibrinolytic enzyme, while the inactive precursor is termed 'profibrinolysin'. The activating principle produced by streptococci, and previously termed fibrinolysin, is called 'streptokinase'. This nomenclature expresses thus the similarity between the system in question and certain other enzyme systems, for example, the formation of trypsin and thrombin.

We have found that profibrinolysin can be transformed into fibrinolysin by an activator contained in animal tissue cells. The occurrence in the animal organism of a process of this type was suggested by Fischer[4].

Ox fibrinogen prepared from Bordet plasma was used. The preparations of ox thrombin contained 10–13 of our thrombin units per mgm.[5,6] (obtained from Løvens Kemiske Fabrik, Copenhagen). All experiments were performed aseptically with sterile solutions.

In a fibrin clot prepared from these solutions, tissue slices from different organs from mammals (ox, pig, rabbit and rat) produced fibrinolysis, the degree of which depended upon the nature of the organ and the species of the animal used. Tissues from chicken and hen were inactive, a fact which is of considerable interest in view of the species specificity disclosed in the proteolytic activity of malignant tissue cells[4]. Streptokinase also was inactive when tested on ox fibrinogen.

Fibrinogen solutions from which the fibrinogen was removed, that is, by heating to 56° for 5 min. or by clotting with thrombin, contained after incubation for 24 hr. with washed tissue fragments at 37° a powerful fibrinolytic enzyme. This indicates the presence of a profibrinolysin in the original fibrinogen solution.

The ability of the tissue to activate profibrinolysin was retained undiminished after several weeks in water containing toluene and chloroform as preservative, and was not dependent on the metabolism of the living cell. It was not found possible to extract the activator from the tissues, but washed suspensions were very active. The activation of fibrinolysin is thus a general property of normal tissue cells. In continuation of the nomenclature mentioned above, we propose to call this activating principle 'fibrinokinase'. The name should really be 'cyto-fibrinokinase', and the activating principle from streptococci should be called 'strepto-fibrinokinase'; fibrinokinase thus being a term for a group of different chemical compounds exhibiting the common property of being able to activate profibrinolysin to form fibrinolysin.

It may be of value to point out the general nature of the principle for producing active substances in the living organism as expressed in the reactions mentioned. Together with the renin-hypertensin system, they represent a type of reactions, in which a tissue component (thrombokinase, renin, fibrinokinase) acts upon a protein circulating in the blood stream (prothrombin, hypertensinogen, profibrinolysin) in order to produce an active substance of high potency (thrombin, hypertensin, fibrinolysin). In addition to the specific inactivating substances present in the blood (antithrombin, hypertensinase, antifibrinolysin), this mechanism serves the organism as a means of regulating the amount of certain substances the formation of which might be dangerous.

A detailed study of the fibrinokinase–fibrinolysin system is being carried out by one of us (P. M. P.), and the results will be published in due course.

Oriented Movement of Blue-Green Algæ on a Stretched Gel

TROPISTIC and tactic responses to stresses in an elastic substrate have been described for several kinds of biological material. The true bacterium *Kurthia zopfii*, when grown in gelatin subjected to mechanical tension, reflects precisely in its pattern of growth the pattern of stresses in the substrate[1-3]; a similar response is shown by nerve fibres cultivated on stretched coagulated plasma[4]. Jacobsen[1] proposed the name 'elasticotropism' for this type of behaviour. A few years ago, the corresponding tactic response was demonstrated in myxobacteria on stretched agar gels[5]. The effect of elasticotaxis in these organisms is particularly striking through its secondary influence on the fruiting process; the rigidly oriented movement of the vegetative cells causes marked abnormalities in the shape and distributional pattern of the fruiting bodies.

Recently I have observed elasticotactic behaviour in two strains of blue-green Algæ belonging to the family Nostocaceæ, received from Dr. T. Gibson, by whom they were isolated in pure culture. It is easy to follow the movement of these organisms on agar, since motile trichomes leave visible 'tracks' on

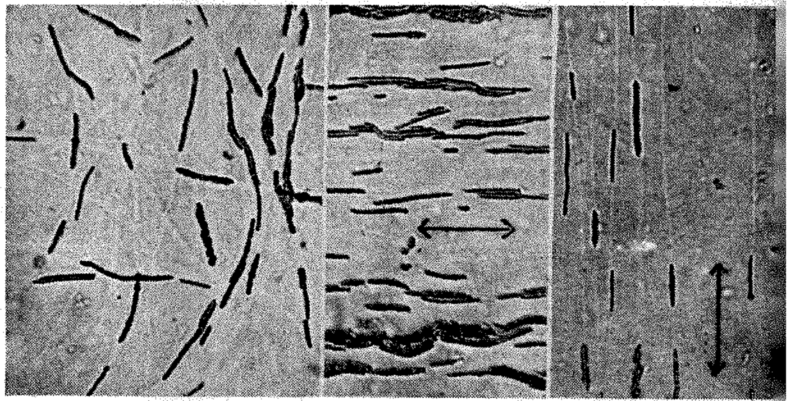

Fig. 1 Fig. 2 Fig. 3

Fig. 1. TYPICAL ARRANGEMENT OF TRICHOMES AND TRACKS ON UNSTRETCHED AGAR

Fig. 2. ORIENTATION OF TRICHOMES ON STRETCHED AGAR. THE ARROW INDICATES THE DIRECTION OF STRESS

Fig. 3. ANOTHER EXAMPLE OF ORIENTATION ON STRETCHED AGAR. THE LINEARITY AND PARALLELISM OF THE TRACKS IS PARTICULARLY CLEAR. THE ARROW INDICATES THE DIRECTION OF STRESS

(Tracks appear as faint light-coloured markings not easily seen in the reproductions.)

the surface of the medium over which they have travelled. When an agar plate is heavily inoculated in one spot and exposed to even illumination, the trichomes creep out evenly from all sides of the inoculum, for the most part following curved paths. Microscopic examination of the agar surface surrounding the inoculum on a plate several days old shows the presence of a large number of randomly oriented trichomes, the areas between them being covered with a network of curved tracks (Fig. 1). However, if the agar is initially subjected to tension (by laying a strip over a glass rod, for example), a markedly different pattern of movement develops. The trichomes move only in straight lines parallel to the applied stress, all migration from the inoculum at right-angles to the stress being prevented. On microscopic examination the trichomes are found to be rigidly oriented with their long axes parallel to the stress, and the tracks appear as a series of beautifully parallel straight lines (Figs. 2 and 3). As the organisms reach areas of decreased tension a certain amount of disorientation makes its appearance, and those trichomes which succeed in reaching a completely unstressed region of the agar regain their liberty of movement, reverting to the normal random orientation and following curved paths. When trichomes pass from an area of tension to one of compression, their orientation changes by 90°. The elasticotactic behaviour of blue-green Algæ is similar in all respects to that of myxobacteria, but the former organisms provide more favourable material for study of the phenomenon, because of their relatively much greater size and their formation of tracks on the substrate.

Since blue-green Algæ and myxobacteria have long been considered to possess similar mechanisms of locomotion, the identity of elasticotactic response in the two groups is not a matter for surprise. It would be interesting to know whether micro-organisms the movement of which on solid surfaces is effected by radically different mechanisms (for example, diatoms and amœboid protists) also respond to this stimulus.

Genetics of Red Body Colour in *Armadillidium vulgare*

Previous work[1,2] and also many unpublished results have shown that in the woodlouse *Armadillidium vulgare* Latr. red body colour and a colour pattern called type *D* behave as simple autosomal dominants to the common black and grey types (the only complication being that in adult animals type *D* is sex-limited to the female sex). Collinge[3,4,5], however, has reported results which do not agree with mine in that he fails to find any segregations. I was inclined to believe that Collinge's results were due to his scoring animals before they were really old enough for the different colour types to be distinguished; for he had stated[6] that, when he examined some young from the variety *rufobrunneus* (red) at just over three weeks old, no trace of red or brown coloration was apparent, and that, if he had not known their history, he would have identified them as young specimens of the variety *plumbeus* (grey-black). While it must be emphasized that in the majority of cases red colour does behave as a simple dominant, and that one does usually obtain good 1 : 1 and 3 : 1 segregations, I have recently obtained some results which confirm Collinge's observations.

The first unexpected result was brood 223 from the red, type *D* female *GN*, which was collected pregnant from Four Went Ways. This brood consisted of 95 black animals and 0 reds. This, of course, can be explained if we assume that there is a recessive gene for red as well as a dominant. Vandel[7] has, in fact, found recessive red types in *Armadillidium vulgare*. Segregation for type *D* in brood 223 was normal, the 92 females consisting of 48 type *B* (the common female colour pattern) and 44 Type *D*.

The second set of unexpected results started with the red, type *B* female *AU*, also obtained already pregnant from Four Went Ways. Brood 185 from this female consisted of 15 red : 35 black. The animals from this brood were numbered *AUA* to *AUF*, and their breeding behaviour is shown in the table below:

Parents		Brood	Segregation	
Female	Male	number	Red	Black
AUA (red)	Brood 185 red male	212	22	0
AUB (red)	Brood 185 red male	213	30	0
AUB (red)	None since brood 213	240	51	0
AUC (red)	Brood 185 red male	214	18	0
AUC (red)	*CRA* (black)	237	0	3
AUD (red)	Brood 185 red male	215	36	0
AUD (red)	*AYA* (black)	245	0	33
AUE (red)	*FM* (black)	238	0	56
CU (red)	Pregnant when collected	187	15	19
CU (red)	None since brood 187	230	33	52
CU (red)	*AUF* (red)	239	53	0

It will be noticed first that red females from brood 185, mated with their own brothers, produce broods consisting of red animals only, and secondly that the same females when mated with unrelated black males produce broods consisting of black animals only. Both these facts would fit the hypothesis that the red colour of female *AU* and her offspring was due to a recessive gene. This explanation, however, probably breaks down when we consider brood 239. Female *CU* was obtained from the Cambridge University Farm, and all other red animals from this locality have always been dominant reds. The segregations in broods 187 and 230 are thus probably due to female *CU* being heterozygous for dominant red and to her having mated with a common black male. If this is so, then male *AUF* appears to be homozygous for dominant red and not for recessive red.

The true explanation of the above results is not yet known, and it is obvious that one easy test, namely, to inbreed black animals from broods 185, 238 and 245, remains to be done. On the other hand, the results may not be explainable on normal Mendelian lines, since it is already known[1,2,8] that sex ratios in *Armadillidium* and other woodlice are peculiar. It is also interesting to note that the Four Went Ways population is peculiar in containing quite a number of intersexes, including the one described by Collinge[9].

AMERICAN AWARDS TO BRITISH MEN OF SCIENCE

THE Medal for Merit, which has its origin in an order by President Washington, is the highest award made by the Government of the United States to a civilian. We print below the names of British men of science recently awarded the Medal, with the accompanying citations:

Sir Edward Appleton, for exceptionally meritorious conduct in the performance of outstanding services to the United Nations. Sir Edward, as secretary of the Department of Scientific and Industrial Research and chairman of the British National Committee for Radio Telegraphy, organised and supported scientific workers, prosecuting many of the important scientific projects which resulted in Allied supremacy. He was outstanding in the effectiveness of his work for co-operation between British and American scientists, and was responsible for important phases of the early research leading to the development in England and the United States of modern radar.

Prof. P. M. S. Blackett, for exceptionally meritorious conduct in the performance of outstanding services to the United Nations. Prof. Blackett, a British pioneer in the field of operational research, not only played a decisive role in the scientific war activities of his own country, but his inspiring leadership stimulated developments in the United States similar to those initiated by him in Great Britain. His brilliant analysis and interpretation of operation data was a major factor leading to the Allied success in the anti-submarine campaign. The value of his work to the United States was outstanding, and his advice and counsel to us were invaluable contributions to the war effort.

Dr. Robert Cockburn, for exceptionally meritorious conduct in the performance of outstanding services to the United Nations. Dr. Cockburn, as head of the Counter-measures Group of the Telecommunications Research Establishment in the Ministry of Aircraft Production, was instrumental in devising new electronic techniques to counter the enemy's use of fire control methods, navigation aids and bombing devices. He was one who early appreciated the high importance of electronic intelligence, and devised equipment and analytical methods to seek out this intelligence. He exerted himself to provide for co-operation between British and American scientists. In the field of radio and radar counter-measures, Dr. Cockburn was the British scientist who above all others had the most comprehensive grasp of the scientific and operational problems involved.

Mr. A. P. Rowe, for exceptionally meritorious conduct in the performance of outstanding services to the United Nations. Mr. Rowe, as head of the great Telecommunications Research Laboratory of the Ministry of Aircraft Production throughout the War, and himself a stimulating and energetic leader of men, exercised a dominant role in the development of radar and counter-measures in the United Kingdom. When American scientists working in these fields proposed to establish advanced laboratories in England, he co-operated enthusiastically, opening his own establishment for their equal use. The inter-Allied discussions at the Telecommunications Research Establishment were famous for their frankness and stimulation. Co-operation was strenuously advocated by him; and in the development and employment of electronics in warfare Mr. Rowe made important contribution.

Sir Reginald Stradling, for exceptionally meritorious conduct in the performance of outstanding services to the United Nations. Sir Reginald, as chief adviser on research and experiments to the Ministry of Home Security from 1940 throughout the War, conceived and directed the far-flung British experiments and observations of the effects of bombs. His revolutionary work led to data of vital importance in the air war with Germany. He pioneered in the measurement of blast, which materially affected the entire study of explosive effects culminating with the atomic bomb. He freely made available to the United States the information and resources at his command. He welcomed and trained many young Americans at his Princes Risborough Station in the techniques he had discovered. Sir Reginald's contributions were of invaluable aid to the Allies in time of great peril.

Sir Geoffrey Taylor, for exceptionally meritorious conduct in the performance of outstanding services to the United Nations. Sir Geoffrey's researches during the War exercised a notable influence on American investigations. His inquiring intellect penetrated into the depths and brought up certain knowledge. He established fundamental truths in fluid dynamics and gas dynamics. He gave inspiration and direction to research in shock-wave propagation, detonation and underwater explosion. His work will continue to influence scientific development, and his contributions were of inestimable value to the war effort.

Sir Henry Tizard, for exceptionally meritorious conduct in the performance of outstanding services to the United Nations. Sir Henry, as leader of the British Technical Mission to the United States in 1940, initiated Anglo-American scientific relations, concluding arrangements for the interchange of information relating to the development of devices for warfare. Later, as scientific advisor to the Air Ministry and member of the Council of the Minister of Aircraft Production, he was a central figure in assuring that research and development as well as operational information of high value in the solution of American problems of aerial warfare, be made available to the United States. Of brilliant mind, gifted with wide imagination, Sir Henry's contribution to the scientific effort of the War was unique.

Sir Robert Watson-Watt, for exceptionally meritorious conduct in the performance of outstanding services to the United Nations. An outstanding authority on radar, Sir Robert's years of work, in a field little frequented, largely formed the basis of the extraordinary early success of British radar when the onset of the War engulfed England in a wave of bombing. His keen technical foresight and ability to organise, with his understanding of human nature, were capitalized in the 'Battle for Britain'. The success attained in the military employment of these new scientific devices and methods inspired and stimulated the great radar programme in the United States. He collaborated in every way with American research groups. In the development and effective combat employment of superior types of radar, radar counter-measures and communications equipment, Sir Robert's services were of enormous value.

LINEN INDUSTRY RESEARCH ASSOCIATION

ANNUAL REPORT

THE report of the Council of the Linen Industry Research Association (from the Association, Lisburn, Northern Ireland) for the year ended September 30, 1946, records that the whole of the inen industry and trade in Northern Ireland are now members of the Association, which has thus become fully representative on a purely voluntary basis. The rate of subscription paid by each individual member has also substantially increased, and the Association has qualified for the maximum possible grants from the Department of Scientific and Industrial Research and the Government of Northern Ireland. Some additions have already been made, to the staff, but in building up a strong, well-qualified body of workers, the Association is in competition with other demands for the limited number of new science graduates available. A good proportion of the Association's staff is trained by the Association, and during the year the value of the Association's scholarship open to first-class honours graduates in science of the Queen's University, Belfast, was considerably increased. Plans have been considered for a new technological building, but this is not expected to be completed for some time.

In pursuance of the new arrangements for keeping members in touch with the latest developments at he Institute, heads of departments are now visiting the individual Scottish members of their section wice yearly. The director and head of the Chemistry Department were members of the linen industry nvestigating mission in Germany during June–July 1946, and the director of research is also a member of the Flax Committee and chairman of its Flax Utilization Sub-Committee. Referring to the large reduction in acreage under flax in Northern Ireland n 1945 and 1946, the Council in its report emphasizes the urgency of research in making the growing of flax more economical in view of this increased dependence on foreign supplies of flax.

Research work noted in the report includes the statistical analysis of records of soil conditions and yields of crops, seed and fibre during 1941–44; studies to determine the effect of time of pulling on retting behaviour and on yield and quality of fibre, and spinning tests of lots of flax from the 1944 crops. An attempt has been made to devise a more objective est than the usual pull-off test for determining the end-point of retting, and an investigation of the causes of low yields with turbine scutching machines has shown that improved yields may be obtained by suitable pre-breaking and proper positioning of the strip by the feed on the conveyor belt and by modification of the beaters. The fifty per cent average loss of efficiency of clean fibre extraction is attributed o factors causing breakage of the fibre strands or straw. Data obtained in an investigation of the relation between fibre qualities and yarn quality have already thrown light on important technical problems.

The hot-air drying of flax yarn in hank form and he levelness of rayon staple yarns spun on flax machinery have also been investigated. Weaving esearch has centred on the performance of warp top motions on looms, modifications to looms and methods of weaving to reduce warp breaks and improve cloth quality, and efficiency surveys in factories.

Work on dyeing and bleaching has aimed at increasing efficiency and improving quality, and particularly at securing the maximum fastness to laundering. In finishing studies, particular attention has been directed to crease-resistant treatments, and work on the proofing of canvas fabrics against attack by various agencies has continued.

ANTIBIOTIC ACTION OF AN EXTRACT OF *GALLERIA MELLONELLA**

By Prof. H. R. OLIVIER

LARVÆ of *Galleria mellonella* are selected in their adult state a little before they begin to form their cocoons. Ground up and the chitinous cuticle filtered off, they are extracted with acetone. This extract is washed three times with $N/10$ sodium hydroxide. The three liquors thus obtained are freed of acetone, neutralized to pH 7·5, and each is concentrated so that 1 c.c. corresponds to 1 gm. of larval bodies.

Tubes containing 10 c.c. of glycerinated veal broth are then inoculated with 0·1 c.c. of a four-day culture of the homogeneous tubercle bacillus of Arloing and Courmont, and to these are added increasing quantities of the extracts of *Galleria mellonella*. The accompanying table shows one of our experiments, the dosages I, II and III representing the successive extractions of the original acetone extract.

	Date	4th	6th	8th	10th	12th	Lysis experiment
	Control	++	++	++	++	++	
I	0·05 c.c.	+−	++	++	++	++	Bacilli of normal aspect
	0·1 c.c.	−	+−	+	+	+	
	0·5 c.c.	−	−	+	+	+	
	1·0 c.c.	−	−	−	−	−	
II	0·01 c.c.	+	++	++	++	++	Bacilli of normal aspect
	0·1 c.c.	+−	+	+	++	++	
	0·5 c.c.	+−	+−	+−	+−	+−	
III	0·01 c.c.	Subtilis					Bacilli clumped, badly staining, and of ill-defined contour
	0·1 c.c.	−	−	+	+	+	
	0·5 c.c.	−	−	Subtilis			

In all our experiments the extracts have begun to show activity at a dosage of 0·1 c.c. If, by analogy with our experiments with 'Endosubtilysine', this is taken as a unit of activity, our extract has an action against the bacillus of Arloing and Courmont corresponding to 30 units per gm. of larval bodies.

We then added to 2 c.c. of a homogeneous culture of the bacillus of Arloing and Courmont, five days old, 1 c.c. of each of the three alkaline liquors I, II and III. After forty-eight hours incubation the mixtures were centrifuged and the deposit stained by the Ziehl method and examined. The bacilli were greatly altered by liquor III, staining badly, and being thickened and ill-defined in contour.

Conclusions. The larvæ of *Galleria mellonella* contain a substance extractable with acetone and possessing an antibiotic action against the homogeneous tubercle bacillus of Arloing and Courmont. In high concentration the extract appears to produce lysis in the same organism.

---

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Tuesday, May 20

Eugenics Society (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Dr. H. J. Eysenck: "Measurement of Socially Valuable Qualities".*

University College (at Gower Street, London, W.C.1), at 5.30 p.m. —Dr. E. J. Holmyard: "History of Chemistry in Islam" (another lecture on May 23).*

Wednesday, May 21

Royal Meteorological Society (at 49 Cromwell Road, South Kensington, London, S.W.7), at 5 p.m.—Prof. O. G. Sutton: "The Problem of Diffusion in the Lower Atmosphere"; Mr. W. G. V. Balchin: "A Microclimatological Investigation of Bath and the Surrounding District".

Royal Society of Medicine, Endocrinology Section (at 1 Wimpole Street, London, W.1), at 5 p.m.—Discussion on "New Aspects of Insulin Action" (to be opened by Prof. F. G. Young (biochemical aspects), and Dr. R. D. Lawrence (clinical aspects)).

Royal Microscopical Society (in the Hastings Hall, B.M.A. House, Tavistock Square, London, W.C.1), at 5.30 p.m.—Discussion on the Programme of the Scientific Film Panel, and an Exhibition of Films.

Institute of Metals (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 6 p.m.—Sir Wallace Akers: "Metallurgical Problems involved in the Generation of Useful Power from Atomic Energy" (Thirty-seventh May Lecture).

Thursday, May 22

Chadwick Public Lecture (at the Town Hall, Cheltenham), at 3 p.m.—Sir Arthur MacNalty, K.C.B.: "Advances in Preventive Medicine during the War of 1939–45".*

London Mathematical Society (at the Royal Astronomical Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Prof. H. Jeffreys, F.R.S.: "Probability".

Mineralogical Society (at the Geological Society of London, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Prof. S. Tolansky: "An Interferometric Survey of Mica".*

Royal Statistical Society (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.15 p.m.—Mr. R. M. Shone: "The Iron and Steel Development Plan—some Statistical Considerations".

Friday, May 23

Society of Chemical Industry, Food Group (joint meeting with the Birmingham and Midland Section, at the Birmingham Chamber of Commerce, New Street, Birmingham), at 2.30 p.m.—Discussion on "Trade Wastes" (Dr. B. A. Southgate: "Effects of Polluting Discharges"; Dr. S. H. Jenkins: "Principles of Trade Waste Treatment").

Royal Astronomical Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Discussion of Geophysical Papers.

Sunday, May 25

Society for Visiting Scientists, the Association of Scientific Workers and the World Federation of Scientific Workers (at the Beaver Hall, Garlick Hill, London, E.C.4), at 7.45 p.m.—Meeting in Memory of Paul Langevin.*

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer in Physical Chemistry, a Lecturer in Pharmaceutical Chemistry, a Lecturer in Metallurgy, a Lecturer in Physics, and a Lecturer in Biology—The Registrar, College of Technology, The Newarke, Leicester (May 24).

Scientific Assistants (women) in the Soil Chemistry Department, East African Agricultural Research Station, Amani, Tanganyika—The Director of Recruitment (Colonial Service), Colonial Office, 15 Victoria Street, London, S.W.1 (May 24).

Lecturer in Chemistry and Metallurgy—The Registrar, Technical College, Sunderland (May 24).

Lecturer in Mathematics—The Clerk to the Governors, Woolwich Polytechnic, Woolwich, London, S.E.18 (May 24).

Senior Research Chemist—The Director, Institute for Industrial Research and Standards, 45 St. Stephen's Green, Dublin (May 24).

Lecturer in Organic Chemistry at the Coventry Technical College—The Director of Education, Council House, Coventry (May 24).

Research Biologist to work in a team studying Plankton Ecology in relation to the Fisheries—The Registrar, University College, Hull (May 24).

Editorial Officer—The Hon. Secretary, Society of Dyers and Colourists, 32–34 Piccadilly, Bradford, endorsed 'Editorial Officer' (May 24).

Senior Assistant in the Department of Metallurgy—The Principal, Central Technical College, Suffolk Street, Birmingham 1 (May 24).

Senior Assistant Lecturer in Mechanical Engineering up to Higher National Certificate standard—The Principal, Handsworth Technical College, Golds Hill Road, Handsworth, Birmingham 21 (May 24).

Senior Assistant for Electrical Engineering, and a Teacher in Mechanical Engineering subjects—The Principal, Municipal Technical College, Hopwood Lane, Halifax (May 24).

Lecturer in Mechanical Engineering subjects in the Ipswich School of Technology—The Chief Education Officer, Education Department, 17 Tower Street, Ipswich (May 24).

Head of the Department of Physics, Mathematics and Navigation, Plymouth Technical College—The Director of Education, Education Office, Coburg Street, Plymouth (May 24).

Assistant Lecturer (Grade III) in the Department of Philosophy—The Registrar, The University, Liverpool (May 30).

Science Editor—The Director, Appointments Department, British Council, 3 Hanover Street, London, W.1 (May 30).

Chief Statistical Officer to the Ministry of National Insurance—The Secretary, Civil Service Commission, 6 Burlington Gardens, London, W.1, quoting No. 1877 (May 31).

Research Scholarship in Vertebrate Zoology—The Registrar, The University, Bristol 8 (June 1).

Chemists (men and women) as Assistant Experimental Officers at the Ministry of Supply Atomic Energy Centre near Preston—The Ministry of Labour and National Service, Technical and Scientific Register, Room 171, York House, Kingsway, London, W.C.2, quoting F.339/47A (June 4).

Chemists (women) in the Scientific and Experimental Officer Classes at the Ministry of Supply Atomic Energy Centre near Preston—The Ministry of Labour and National Service, Technical and Scientific Register, Room 171, York House, Kingsway, London, W.C.2, quoting F.330/47A (June 4).

Professor of Electrical Technology at the Indian Institute of Science, Bangalore—The High Commissioner for India, Genera Department, India House, Aldwych, London, W.C.2 (June 7).

Senior Organic Chemist in the Biochemistry Section for work on the organic constituents of fruit-bearing plants—The Secretary, East Malling Research Station, East Malling, Kent (June 7).

Animal Husbandry Officers (2) in the Department of Agriculture and Lands, Southern Rhodesia—The Secretary, Office o the High Commissioner for Southern Rhodesia, Rhodesia House, 429 Strand, London, W.C.2 (June 7).

Research Officer, Timber Preservation Section, Division o Forest Products, Melbourne—The Secretary, Australian Scientific Research Liaison Office, Australia House, Strand, London, W.C.2, quoting No. 1187 (June 9).

Lecturer in the Department of Social Studies, and an Assistant Tutor in Practical Social Work—The Registrar, The University, Leeds 2 (June 9).

Readership in Applied Mechanics at the Imperial College o Science and Technology—The Academic Registrar, University o London, Senate House, London, W.C.1 (June 12).

Principal Scientific Officer at the Armament Design Department of the Ministry of Supply, Fort Halstead, Kent—The Secretary, Civil Service Commission, 6 Burlington Gardens, London, W.1, quoting No. 1871 (June 14).

Principal Scientific Officer at the Telecommunications Research Establishment of the Ministry of Supply, Malvern Worcs.—The Secretary, Civil Service Commission, 6 Burlington Gardens London, W.1, quoting No. 1870 (June 14).

Professor of Mining—The Registrar, University College, Nottingham.

Meteorological Assistants (both sexes)—The Under-Secretary of State, Air Ministry (S.2b), Cornwall House, Stamford Street London, S.E.1.

Lecturers (3) for Mechanical Engineering subjects to the Higher National Certificate and University Degree standard, and a Lecturer in Physics to London University special degree standard—The Clerk to the Governors, South-West Essex Technical College and School of Art, Forest Road, Walthamstow, London, E.17.

Technician in charge of the new Clinical Photographic Department—G. Hurford, Queen Elizabeth Hospital, Birmingham 15.

Laboratory Technician—The Medical Superintendent, Notts County Mental Hospital, Radcliffe-on-Trent, Notts.

Instrument Research Officer, and an Experimental Office for testing dairy plant and equipment—The Secretary, Nationa Institute for Research in Dairying, Shinfield, Reading.

Senior Laboratory Steward for Science Department—Th Principal, County Technical College, Essex Road, Dartford.

Lecturer and Demonstrator in Agricultural Chemistry—The Principal, Harper Adams Agricultural College, Newport, Shropshire.

Lecturer in Chemistry—The Clerk to the Governors of th Technical College, Education Offices, North Street, Wolverhampto

Physical Chemist for work in connexion with Steelmaking, Slag and Refractories—The Personnel Officer, British Iron and Ste Research Association, 11 Park Lane, London, W.1, quoting 'Refractories Section'.

Physicist to work mainly on the physical properties of leathe rubber, plastics and other shoe materials, and a Statistical Mathematician to work on foot measurement surveys of the population—The Director, British Boot, Shoe, and Allied Trades Research Association, Satra House, Rockingham Road, Kettering, Northants.

Lecturer or Assistant Professor in the Department o Biochemistry—The Professor of Biochemistry, Faculty of Medicin University of Manitoba, Winnipeg, Canada.

Laboratory Steward (Grade IIA) for Organic Chemistry—The Registrar, The University, Leeds 2.

Senior Assistant in the Department of Civil and Mechanica Engineering to teach Advanced Theory and Design of Structur and Surveying, a Senior Assistant in the Department of Chemistry to teach Physical Chemistry to Final B.Sc. (special) Degr standard, and a Lecturer in Chemistry to teach Organic Chemistr to Final B.Sc. (special) Degree—The Principal, Technical Colleg Queen Street South, Huddersfield.

Senior Assistant in Mechanical or Civil Engineering, Lecturer in Mechanical Engineering subjects, a Lecturer Electrical Engineering subjects, and a Senior Laborator Steward in the Chemistry and Biology Department—Th Registrar, Municipal College, Portsmouth.

Lecturer (graduate) in Chemistry in the St. Helens Municip Technical College—The Director of Education, Education Offic St. Helens.

RESEARCH ASSOCIATIONS AND INDUSTRY

THE Board of Trade Working Party for the Linoleum and Felt Base Industry*, which included as independent members Dr. L. T. M. Gray and Prof. J. Read, leaves no room for doubt as to the importance of scientific research to that industry. The main and over-riding shortage in the industry at present is linseed oil, the supply of which has been cut to thirty per cent of the pre-war supply. This shortage is closely bound up with the world shortage of edible oils and fats, and no substantial improvement in the supplies of linseed oil for the industry is likely this year. Various substitutes for linseed oil have been tried, notably an adipic ester of trimethylolpropane in Germany, and the Working Party recommends that the industry should continue vigorous research on possible substitutes for linseed oil.

This position alone establishes the importance of scientific research to the development of the industry, even from the point of view of the supply of raw materials. While it is clear that the Government could do something more to help the industry by the provision, as the Working Party suggests, of regular information as to the short- and long-term prospects of supplies of linseed oil in view of the possible greater expense of linseed oil substitutes and the modifications to plant which may be involved, and by no longer insisting on a reduction in the allocation of linseed oil in exchange for supplies of substitute materials, the industry does not seem to be doing all that it might to help itself. A total expenditure of only £46,650 on research by nine out of the fourteen firms represents only 0·5 per cent of the turnover, and of these firms two spent an average of more than £5,000 on research during the five years 1936–39 and 1945, while three others spent between £1,000 and £3,000.

When all allowance is made for variations in size of the firms, the figures certainly suggest that several firms have not yet recognized sufficiently the need for research in an industry the future of which may well depend largely on developments in plastic materials. Linoleum itself, as the Working Party notes, is based on a form of plastic material. Further, the processes of the manufacture of linoleum are dominated by chemical changes, which are imperfectly understood. Further research might well lead to far-reaching economies in manufacturing processes, either in the use of power, as the Working Party suggests, or through the utilization of new raw materials to meet the shortage of linseed oil which, as already noted, is likely to persist for some years.

From the point of view of research, the first impression made by this report is the dynamic character of the industry to-day. It is a section of the organic chemical industry, and shares the characteristics, hazards and opportunities of that industry. Its prosperity and development may well be expected to depend on the same factors that have contributed to the development of chemical industry in general in Great Britain. Any special pleading on behalf of the linoleum industry should accordingly be excluded *a priori*, nor does the Working Party appear to advance such pleading. On the contrary, it suggests that the industry, which is too small to carry its own central research organisation, should make more use of the existing research organisations. Reference is made, in particular, to the Paint Research Station, though it is probable that the National Chemical Research Laboratory could also be of service.

* Board of Trade. Working Party Reports: Linoleum and Felt Base. Pp. viii+49. (London: H.M. Stationery Office, 1947.) 1*s*. 6*d*. net.

Dr. J. L. Simonsen assisted Prof. Read in visiting the Paint Research Station at Teddington and reporting on the suitability of that station as a research centre for the industry. The sub-committee was very favourably impressed by the quantity and range of the work now being conducted in the Paint Research Laboratory, and considers that the Laboratory offers a valuable nucleus of buildings, equipment and staff which could be expanded with great benefit to the linoleum and felt base industry. It is suggested that, as a first step, the Paint Research Station should develop a special section to take up long-term researches with a direct bearing on linoleum and felt base. This would involve a high priority for building the expansion of the Paint Research Station's premises which is already projected, and it also implies membership of the Paint Research Association by all linoleum and felt base manufacturers, who would thus make an adequate contribution to the research association, earning in turn the usual grant from the Department of Scientific and Industrial Research.

On this proposal there are two comments to be made. The majority of the firms engaged in the manufacture of linoleum and felt base are located in the Dundee or Fife neighbourhood, and are accordingly remote from the Paint Research Station at Teddington. This disadvantage can be exaggerated, but there is this much substance in the proposals from the Scottish Reconstruction Committee, echoed at the recent Scottish Regional Conference of the Federation of British Industries, for the establishment of a Scottish Department, that the Department of Scientific and Industrial Research has in the past tended to overlook the value of the geographical proximity of a research station to the industry it serves primarily. Such proximity is of particular importance for a research association in that it helps to overcome the technical isolation in which the association must work as compared with the research department of an industrial firm.

The proposal to establish a coal utilization research station in the south of England and not on one of the coalfields is a striking example of the Department's failure to appreciate the importance of this factor. While such departmental neglect affords no warrant for such fantastic proposals as the duplication of the Department of Scientific and Industrial Research in Scotland, it does lend some support to the alternative proposal ventilated by Dr. R. Hay at the Federation of British Industries Conference and hinted at rather than advanced in the present report. If the establishment of a separate institute for long-term research relating to the linoleum and felt base industry is scarcely justified, the endowment of one or more industrial fellowships for the purpose at an institute of the type of the Mellon Institute located within easy reach of the main manufacturing area might be an equally or more effective measure than the development of a special section at the Paint Research Station at Teddington.

The admirable report which has since come from the Working Party for the Wool Industry* contains a proposal which bears on this suggestion. Discussing the special problems of the industry in Scotland, it is proposed that the production centre to be developed in connexion with the Scottish Woollen Technical College at Galashiels should be linked with a design centre and a research centre, thus providing a first-rate educational centre for all matters relating to the woollen industry. Fundamental research would continue to be confined to the existing research centres at the University of Leeds and Torridon; but it is suggested that many problems, particularly in mill organisation, machinery, materials and processes, could be dealt with at Galashiels, and that a research section there would stimulate firms to a realization of the problems lying around them, with the solution of which technical advances may be made.

Attractive as such a suggestion may appear at first sight, particularly in relation to technical education and the fostering of research at technical colleges, it will require very careful examination both in regard to its effect on the existing research association and in relation to the alternative idea of endowing fellowships at a Scottish institution of the type of the Mellon Institute. In the first place, apart from the present stringency of resources for research, both in materials and equipment as well as in man-power, there is real danger of dissipating our effort in relatively ineffective or inefficient undertakings. Elsewhere in its report, the Working Party records its conviction that the funds available for research in the industry have been quite inadequate, and that the present unsatisfactory relations that exist between the Textile Department of the University of Leeds and the Wool Industries Research Association at Torridon, and between these institutions, the technical colleges and the firms themselves, would be largely remedied by increased expenditure on research.

In the second place, it may be observed that the outlook in the industry, as disclosed in this report, does not encourage much optimism as to the local support which would be forthcoming for a new research centre at Galashiels. It is suggested that this research centre will serve to meet the needs of the smaller firms who do not employ physicists or chemists; but this argument overlooks the fundamental factor that it is the absence of technical men in these firms which is responsible for the unsatisfactory attitude to research and for the inability to apply the results of scientific advance. The attitude of many supporters of the Association at Torridon, quoted in the report, who, recognizing the high value of the discoveries made at the University of Leeds, argue that such results are of equal value to their competitors

* Board of Trade. Working Party Reports: Wool. Pp. vii+232. (London: H. M. Stationery Office, 1947.) 3s. 6d. net.

and object to the publication to the world of the results for which they subscribe for their own special use, indicates that a real change of atmosphere as well as close co-ordination is required. Furthermore, just as with the linoleum and felt base industry, many of the problems calling for research, such as dyeing problems, raw materials and machinery, and the use of substitutes, involve links with other branches of industry and can profitably be investigated by co-operative effort between industries.

That in itself is an argument for trying the idea of the industrial fellowship at an institute of the type of the Mellon Institute, and indeed indicates the character of the problems which should be referred to any such institute. Meanwhile, the Working Party has made out a convincing case for an advisory research council, even if its recommendation that the time has come for the textile industries to pool their ideas on research and set up a national textile research council for the whole of the textile industries is more debatable. The Working Party does not suggest that the joint advisory wool textile research council which it proposes should concern itself with the details of investigations; but it would be charged with the duty of arranging that the respective types of investigation cover the necessary ground, it should eliminate undue overlap, and encourage friendly co-operation. One of the principal tasks of the proposed council would be to deal with the problem of secrecy, which appears to be such a bugbear in the industry.

The Working Party suggests that the Department of Scientific and Industrial Research or other Government authority should invite representatives of universities, the technical colleges, the Wool Industries Research Association, the employers, trade unions and some independent persons to meet to establish such a council. Meanwhile, it expresses complete approval of the application of the Wool Textile Delegation to the Board of Trade for a statutory evy to raise £150,000 for general research purposes, of which £100,000 would be assigned for scientific research and the rest for market research. It suggests, however, that up to 25 per cent of the first sum should o to meet the needs of universities and technical colleges engaged in textile research, and that this amount would be administered by the proposed esearch council, which should also be responsible for administering on the same lines the sum of £100,000, which should be set aside from the export levy for he promotion of research.

The Working Party, in making these proposals, hows the same wide outlook as the Working Party for the Cotton Industry did in its report last year. he main proposal involves the use of the proceeds of a statutory wool levy for purposes that include development of other fibres, and it is recommended that the proposed research council should invite other industries to co-operate in such research and o contribute to its cost. Like the Cotton Working Party again, it is impressed with the need for undamental research in the design of textile machinery, and suggests that the textile machinery-making industry should set on foot a textile machinery research association to work in close alliance with the existing research associations of the textile trades. Similarly, close liaison should be established with existing research and development institutions concerned with problems of fuel and power, to promote increased efficiency, convenience and cleanliness. It is also recommended that the present tendency towards development work as joint efforts of research centres and individual firms should be fostered. The Research Association should have at its disposal greater facilities for the experimental testing of suggestions for general experimental work on production problems, either in the form of development units or other plant in suitable premises. The present buildings at Torridon are condemned as unsuitable, and erection of a new research station as soon as possible on a much more comprehensive scale and in a central position is recommended.

These proposals show that, while critical of the Woollen Industries Research Association, the Working Party is agreed that it should be continued, and that it should receive fuller support, both financially and in other ways. For this reason the comments under the heading "Liaison and Information" are instructive. True appreciation of the spirit, meaning and implications of research is still, in the view of the Working Party, disappointingly low both among the general public and in the wool industry; and often people in responsible positions, who subscribe freely to the Research Association, have only the vaguest idea of the method and significance of what is being done. Many of the findings of research are failing to penetrate into the very places where they are needed, mainly because the language and technique of communication are inadequate.

The Working Party recognizes that only a rise in the general standard of textile education will permit a satisfactory solution, and that the trade press, which is the normal agency through which new knowledge reaches the industry, must carry a considerable share of responsibility. It also welcomes the new Department of Scientific and Technical Liaison now being set up by the International Wool Secretariat, and it is implicit in the report that the Research Association itself should give more attention to the efficiency of its liaison and information services.

Even more important, however, than the emphais of this report on the co-ordination of relations between existing research institutions is the attention directed to the true functions of a research association. Not even the report of the Cotton Working Party is calculated to stimulate more fundamental thinking about this question, and in view of Prof. Polanyi's plea at the recent British Association conference in Manchester, it is interesting to note how firmly this report insists with him that the university research departments are the chief sources and true homes of fundamental research. The main nourishment of the research associations, as of industrial research in general, must thus come from the scientific work of the universities; but the university research departments in turn will profit from adequate contact with industry, whether or not that is made through research associations.

The first function of the research association, in the view of the Wool Working Party, is to seek in its appropriate industry the broad problems and processes involved, and to submit them to careful scrutiny in the light of the best scientific knowledge available. Its second main function is to see that fundamental advances take the quickest possible path to industrial practice. To discharge these functions it is suggested that the Research Association must carry out some fundamental research of its own as well as investigate *ad hoc* problems submitted by its member firms. But the Working Party does not proceed to discuss the questions that naturally arise out of this: the nature rather than the volume of fundamental research appropriate for a research association; and the effectiveness of its *ad hoc* investigations as compared with those made by the research department of an industrial firm.

These, however, are the questions that require examination before there is any large-scale expansion of the research association movement or any decision as to its future. Further, the Wool Working Party recognizes that no amount of work by a research association can be a substitute for actual participation in research by individual firms. Meanwhile, the observations in this report on the position of textile research at the University of Leeds underlines all that was urged at the British Association Conference in Manchester regarding the endowment of university research and the importance of full freedom of investigation. Any attempt to co-ordinate all fibre studies, wherever carried out, through the establishment of a National Textile Research Council, working in close collaboration with the Textile Institute and the Society of Dyers and Colourists, as proposed in this report, cannot but lead to the study of these questions at the outset, and may in doing so render a real contribution to that overdue, factual and impartial appraisal of the position of the whole research association movement in Great Britain.

There is much in these two reports which deserves the close attention of scientific workers, from both the industrial and the academic point of view; and if the productive efficiency of Great Britain is to be raised to its appropriate level, the general and fundamental problems which they indicate in regard to the organisation of our research effort should be frankly faced, and waste of scientific effort and man-power avoided. Important as is this aspect, however, there should not be overlooked those questions of human relations which are also brought out, and the contribution which science can make in this field also. In the proposals for a joint advisory council, interrelated with like bodies for other major industries in the field of textiles, we see a tentative approach to the elaboration of a new form of industrial democracy, which by promoting fuller understanding between employers and employed in the attack on common problems, may help to solve that basic problem in the raising of the standard of efficiency and output of British industry as a whole—the creation of an atmosphere of mutual confidence, goodwill and common purpose.

ELECTROCHEMISTRY OF RADIOACTIVE SUBSTANCES

Électrochimie des substances radioactives et des solutions extrêmement diluées

Par M. Haïssinsky. (Radioactivité exposés publiés sous la direction de Prof. A. Debierne, 2.) (Actualités scientifiques et industrielles, 1009.) Pp. 68. (Paris: Masson et Cie., 1946.) 125 francs.

THIS short book by an authority on the subject is very welcome at the present time, when the supply of artificial radio-elements is on the verge of abundance. *Inter alia*, the preparation of radioactive sources must shortly become a routine operation in many fields of research, and, for this, electrochemical methods are often superior to all others in convenience, and in the purity and homogeneity of the product.

Introductory and descriptive in nature, the first three chapters deal successively, in general terms and from a practical point of view, with the chemistry of the radio-elements, with their electrochemistry (the phenomenon of spontaneous deposition, leading them to true electrolysis), and with technical details of apparatus and methods.

The fourth chapter, perhaps the most important one, discusses, on theoretical grounds, the formation of extremely thin electrolytic deposits. To account for previously observed facts, Herzfeld had modified the Nernst equation to deal with those cases where quantities insufficient to form even a monatomic layer are deposited; in so doing, however, his equation led to some conclusions which experimentally could not be verified. By the assumption of active centres, where deposition preferentially occurs, Haïssinsky argues that the Nernst equation does hold in extremely dilute solution, in the earliest stages of deposition, and shows that this is not necessarily in disagreement with Herzfeld's modification. It is unfortunate that there should still be uncertainty as to the applicability of the Nernst equation at concentrations of the order of 10^{-12} N. The earlier work of Hevesy and Paneth, Wertenstein, and Joliot using polonium in a rather narrow concentration range (10^{-8}–10^{-11} N), gave no unambiguous Nernst shift with concentration. Later work by Haïssinsky[1] with active isotopes of bismuth, in the rang 10^{-5}–10^{-12} N, indicated that such a Nernst shift doe occur, and on this he bases the affirmation of p. 26 Recently declassified work by H. G. Heal[2], however using polonium, in concentrations of 8×10^{-13} and 10^{-13} N, gives a deposition potential of still $+ 0{\cdot}6$ volt, and he denies the applicability of the equatio at these concentrations.

Part of the difficulty lies, as Haïssinsky points ou later (p. 47), in the use of elements of high valenc (for polonium, a 100-fold concentration change pro duces a calculated potential change of only 0·028 vol —less than experimental differences in measurement on the same solution). Also, the tendency of poloniu to form complexes with the great excess of anion present may obscure interpretation of results obtaine with this element. It is to be hoped that the unce tainty may soon be eliminated, perhaps by the u of a radio-element of lower valency, the electr chemistry of which is already well known (f example, radio-silver).

From the theoretical discussion, the author turn to the electrochemistry of the elements of the natur radioactive series. This, as a summary of practic work, chiefly on the electrolytic deposition of t individual elements of the series from solution and the fused state, should be of great assistance to those wishing to prepare sources for radiochemical, physical, and biological use. A discussion of artificial radioelements and their electrochemical properties—a section necessarily short because of recent conditions—concludes this valuable book. F. MORGAN

EMBRYOLOGY FOR MEDICAL STUDENTS

Human Embryology

By Prof. Bradley M. Patten. Pp. xv + 776. (London: J. and A. Churchill, Ltd., 1946.) 45*s*.

LITTLE more than a year ago a new English text-book of human embryology had a somewhat mixed reception in these columns[1]. Criticisms were that it did not refer to the work of certain British men of science; that a few features in some diagrams were incorrectly labelled; and that here and there the text could have been expanded to advantage. To-day another text-book with precisely the same title is addressed to medical students by Prof. Patten, a well-known and much esteemed American embryologist. It is slightly longer; slightly more lavishly, if not as well (although this is largely a matter of taste), illustrated; it covers almost the same ground; and doubtlessly it is open to some of the same criticism. It would be surprising if it were otherwise. In a subject like topographical embryology, where ideas on the genesis of organs represent dynamic concepts based on successive 'still' views of developmental processes, there is ample opportunity for differences in individual interpretation and emphasis; and furthermore, so much scope that no one person could be expected to have a first-hand knowledge of every part of the whole field.

The purpose of Prof. Patten's book is to present to the medical student a conspectus of human morphogenesis. In this, like the English volume it follows, it succeeds admirably. If either were mastered the student would know far more about general embryology than a very high proportion of lecturers and demonstrators in British anatomical departments to-day—and by the same token very much more than his clinical teachers. No doubt undergraduates are already trying to do this, for the book of a year ago is already sold out, and this is almost certain to be the fate of Prof. Patten's very readable addition to the literature of embryology.

The very fact that this is so makes one ask whether it is right to expect the average medical student to attempt as much as is covered by Prof. Patten. Prof. Patten recognizes that the medical curriculum is overcrowded, and the consequent necessity to confine his book to a 'reasonable compass'. Anatomists who have specialized in embryology may agree with him that seven hundred pages of text is a reasonable compass; and others will as cordially argue that it is far too much. The difficulty here is that, to the man who has not made organogenesis a speciality, the case for devoting to the subject a large part of the anatomical curriculum often appears much overdone—and indeed at times pressed out of the bounds of all practical possibility. Protagonists of embryology offer the excuse that the subject helps to rationalize the topographical detail of anatomy; to understand the basis of the occasional abnormality met with in clinical practice; to appreciate certain of the problems of obstetrics; and above all, that it has a major intellectual or cultural value. Item by item few would bother to dispute any of this. Yet to state that a detailed understanding of the unfolding of a topographical pattern in the embryo is a basis for comprehending the detailed pattern in the adult is to come close to the statement of a tautology. To insist that a study of embryology helps the student to understand the occasional congenital abnormality met with in clinical practice is also to state the obvious; and suggests the logical conclusion that proportionately as little time should be devoted to the subject as is taken up in clinical practice by malformations. To state that the subject has a cultural value is merely to underline what should be a quality of the entire curriculum of the medical student. One may well ask oneself whether the whole pattern of these considerations is important in the educational problem which the average medical student constitutes.

For in any event the student has to take embryology very much as a matter of faith. In Great Britain he practically never examines a section of a human or pig embryo, still less a set of serial sections—among other good reasons, for the very important one that adequate study of such material is a very time-consuming affair. Consequently the 'stills' and diagrams of his text-books represent the only direct experience the average student has of dynamic developmental processes. Such slender foundations scarcely sustain a scientific discipline. Even if they did, it is difficult to see what particular good it would be to the budding medical man. Books like Prof. Patten's are, in short, admirable guides for the student who has the opportunity and desire to study organogenesis in the laboratory itself. But they are much more than is wanted—to quote his own words—for the successful understanding of "the emergence of the various organ systems from undifferentiated primordial tissues to a point where he can recognize the beginnings of familiar adult structures"—which is about all one is likely to ask of the average medical student of to-day. What he wants is some short text that briefly explains what is known about the recognized principles of morphogenesis, and which is illustrated by really competent diagrams of the main stages in organogenesis. Since we are dealing with processes, and not fixed structures, it would be still better if one could call upon the talents of a first-class producer of 'animated films' to provide really good films of embryonic development. That would still be several steps from the original material of the subject; but it would be far closer than the student gets to-day.

For all this, there can be little doubt that Prof. Patten's main reading public will, in fact, be hurried medical students. One hopes, however, that it will receive more earnest employment as well. For topographical embryology does not need to be excused by over-emphasizing its utilitarian value in medical education. It stands in its own right, as an essential part of the story of development—and without which morphology would be only half a science. From this point of view we may count ourselves as lucky that there are always some departments of anatomy that provide the subject with a secure home. S. ZUCKERMAN

HÆMOGLOBIN AND NITROGEN FIXATION IN THE ROOT NODULES OF LEGUMINOUS PLANTS

By PROF. D. KEILIN, F.R.S., and J. D. SMITH
Molteno Institute, University of Cambridge

IT has been shown by Kubo[1] that the root nodules of leguminous plants contain a hæmoprotein compound resembling hæmoglobin and probably acting as a store as well as a carrier of oxygen. The hæmatin nature of this pigment was confirmed by Burris and Haas[2], who believed, however, that it was not a hæmoglobin-like compound which could undergo oxygenation, but rather an oxido-reduction catalyst in which the iron changes its valency. That this pigment is a true hæmoglobin was demonstrated by Keilin and Wang[3], who purified it and found that: (1) it forms a perfectly reversible compound with molecular oxygen; (2) it has a high affinity for oxygen, the p_{50} at 15° being less than 0·1 mm. mercury; and (3) the relative affinity of this pigment for oxygen and carbon monoxide in terms of the equilibrium constant $K = [\mathrm{HbCO}]\,[p\mathrm{O}_2]/[\mathrm{HbO}_2]\,[p\mathrm{CO}]$ is about 37 at 15° C. They also determined the spectrophotometric absorption curves of this hæmoglobin and of its compounds with oxygen and carbon monoxide.

The constant presence of this pigment in effective nodules of all leguminous plants, and the fact that nitrogen fixation in these nodules is inhibited by very low partial pressure of carbon monoxide, suggested that the hæmoglobin is in some way connected with the process of nitrogen fixation.

The presence of hæmoglobin in nodules was confirmed by Virtanen[4] and by Virtanen and Laine[5]. They, however, claimed that in addition to hæmoglobin the root nodules always contain methæmoglobin, the concentration of which increases when the plants are placed in the dark. They assumed that in nitrogen fixation the function of hæmoglobin is connected not so much with its property of oxygenation to oxyhæmoglobin as with its oxidation to methæmoglobin.

It must be remembered that whereas hæmoglobin (Hb) and oxyhæmoglobin (HbO_2) are compounds of divalent iron, methæmoglobin (Methb), which is a true oxidation product of hæmoglobin, contains trivalent iron.

In the present communication we propose to give a brief account of our study of the state of hæmoglobin within the nodules of plants kept under different conditions, and to examine the suggestions put forward by Virtanen and Laine[5] as to the mode of action of hæmoglobin in the nitrogen fixation by nodules.

State of Hæmoglobin in Nodules of Plants in the Light and in the Dark

The plant used in our investigations was the soya bean. The nodules were produced by three strains of *Rhizobium*: 505 and 507 supplied by Dr. H. G. Thornton of Rothamsted Experimental Station, and the strain 2196 obtained from the National Collection of Type Cultures. Two of these, 505 and 2196, were 'effective' strains, whereas the strain 507 was 'ineffective'. The experiments were carried out between June and September 1946 with plants grown either in nutrient solutions or in soil, and the seeds were germinated either in sterilized sand or in unsterilized soil. The state of the hæmoglobin was determined by direct spectroscopic examination of nodules immediately after their removal from the roots. For this purpose each nodule is washed, and cut with a razor blade into three slices. The central slice with parallel surfaces is placed on a slide in a drop of water and examined with the microspectroscope, using a strong source of light. Other nodules were examined crushed between two slides. Oxyhæmoglobin was recognized by the absorption bands at about 574 and 540 mμ, hæmoglobin by a single band at 557 mμ, whereas methæmoglobin, if present, should show a band at about 630 mμ. In certain cases sodium fluoride was added to the crushed or sliced nodule, which was then examined for the band of fluoride methæmoglobin lying at about 610 mμ.

Plants grown in nutrient solutions. On the opening of the second pair of leaves the seedlings, grown in sterilized sand, were transferred to 1·5 l. conical flasks containing a nutrient solution. The plants were inoculated by the addition to the nutrient solution of a suspension of a pure culture of *Rhizobium*. Three sets of plants nine weeks old bearing nodules produced by strains 505, 507 and 2196 of *Rhizobium* were each divided into two groups, one of which was left with the tops exposed to light, whereas the plants of the other groups were protected from light by wire cages covered with black cloth.

After eight days, several specimens of plants belonging to each of the six groups were removed and their nodules were examined spectroscopically. The main results of this examination can be summarized as follows: (1) nodules produced by the ineffective strain 507 were devoid of hæmoglobin both in specimens kept in the light and those in the dark; (2) nodules produced by effective strains (505 and 2196) contained only hæmoglobin and oxyhæmoglobin; no methæmoglobin was visible even in nodules of plants kept in the dark for about eight days; (3) on the addition of sodium fluoride to crushed nodules the band of fluoride-methæmoglobin, which slowly appeared, was very feeble and of the same intensity in nodules from plants kept in light and those in the dark.

Plants grown in soil. The seedlings were inoculated with a suspension of strain 505 of *Rhizobium*, and seventeen days later they were separated into two groups: the plants of one group were left in light, whereas those of the other group were transferred to closed containers in a darkened part of the greenhouse. Samples of both groups of plants were taken out and their nodules examined spectroscopically. After two and four days in the dark, only hæmoglobin and oxyhæmoglobin were present in the nodules, and no trace of methæmoglobin could be detected. After twelve days in the dark the leaves of the plants were yellow and falling. The contents of the nodules were brown and devoid both of hæmoglobin and methæmoglobin. The total hæmatin content of such nodules estimated as pyridine hæmochromogen was much lower than that of the nodules from normal plants.

This experiment was repeated using older plants which had begun seed production and were bearing larger nodules. Here again, in plants kept in the dark and examined daily, no methæmoglobin could be detected by direct spectroscopic examination of crushed or sliced nodules, and only after seven days in the dark was a small amount of fluoride-methæmoglobin formed on addition of sodium fluoride to crushed nodules.

Localization and Concentration of Hæmoglobin Within Nodules

We found it possible to demonstrate that within the nodule hæmoglobin is confined to the large cells containing *Rhizobium.* This was done either by direct microspectroscopic examination of thick slices of nodules, or by observing the distribution of the blue colour produced by the peroxidase action of hæmoglobin in microtome sections of nodules about 10 mμ in thickness treated with benzidine and hydrogen peroxide.

The concentration of hæmoglobin in the bacteria-containing cells of dwarf bean (*Phaseolus vulgaris*) nodules, estimated in crude extracts of nodules as pyridine hæmochromogen, was found to be about $1 \cdot 1 \times 10^{-4}$ gm. mol. hæmatin/l. The mean value obtained directly in slices of nodules and including hæmatin of cytochrome was $2 \cdot 3 \times 10^{-4}$ gm. mol. hæmatin/l. These estimations were carried out with the microspectroscope and the double-wedge trough, as previously described[6,7].

Hæmoglobin and Nitrogen Fixation in Nodules

Before the red pigment in nodules was recognized as hæmoglobin, Virtanen and his co-workers suggested that the first product of nitrogen fixation in nodules is hydroxylamine (NH_2OH), and that this combines with oxalacetic acid produced in the green portion of the plant to form the oxime, which on reduction gives rise to *l*-aspartic acid.

When the presence of hæmoglobin in nodules was definitely demonstrated[1,3], Virtanen and Laine[5] made an attempt to correlate its function with their hydroxylamine–aspartic acid mechanism of nitrogen fixation. For this purpose they found it necessary to postulate the valency changes of hæmoglobin iron and the reversibility of the reaction of decomposition of hydroxylamine by hæmoglobin.

According to Virtanen and Laine[5] the part played by hæmoglobin in nitrogen fixation can be represented schematically as follows:

$$\begin{array}{rcl} N_2 + \text{Methb (Fe}^{\text{III}}) & \rightleftharpoons & NH_2OH + \text{Hb (Fe}^{\text{II}}) \\ & & \big\downarrow + \text{oxalacetic acid} \\ l\text{-aspartic acid} & \xleftarrow{\text{reduction}} & \text{oxime} \end{array}$$

That the mechanism of nitrogen fixation involves a cyclic change of the valency of hæmoglobin iron is, according to them, supported by the following considerations: "The changes in the colour of nodules . . . depend on the intensity of light, and follow to a surprising extent the variations of oxalacetic content of the plant juice. On bright days the oxalacetic acid content of the plant juice is at its highest; during cloudy periods it falls sharply and after forty-eight hours in total darkness disappears completely." Accordingly, they claim to have found that "during cloudy days the brown colour deepens in the nodules as the balance is shifted to methæmoglobin".

The hydroxylamine–aspartic acid theory has already been carefully examined by Wilson[8] in his masterly review of the whole subject of nitrogen fixation in plants. We therefore propose to deal only with the views put forward by Virtanen and Laine[5] as to the mode of action of hæmoglobin in nitrogen fixation by root nodules. Even if their hydroxylamine–aspartic acid mechanism is accepted, several considerations, which we shall briefly examine, militate against their views of the part played by hæmoglobin in this mechanism.

(1) Our experiments failed to confirm their observations as to the presence of methæmoglobin in root nodules of plants even when the latter were kept in darkness for several days. On spectroscopic examination nodules show only the absorption bands of oxyhæmoglobin, which are gradually replaced by the single band of hæmoglobin. This deoxygenation, which is due to the normal respiratory activity of nodules including *Rhizobium*, is more rapid when nodules are examined compressed or crushed between two slides. The appearance of methæmoglobin in Virtanen and Laine's experiments was probably due to the fact that they worked with nodule extracts in which hæmoglobin undergoes oxidation by quinones formed during the extraction. In fact, the formation of methæmoglobin is more rapid in extracts from nodules of peas and beans, which are particularly rich in the polyphenol oxidase system, than in those of soya bean.

(2) The brown colour of nodules observed by Virtanen and Laine was not necessarily due to the formation of methæmoglobin, since the brown coloration of degenerating nodules, like that of other damaged plant tissues, may be due to the products of oxidation of phenolic substances by a polyphenol oxidase.

(3) Their statement that "methæmoglobin is reduced to hæmoglobin by the action of oxalacetic acid" is misleading, since oxalacetic acid reduces neither methæmoglobin nor any other hæmatin compound.

(4) The mechanism of decomposition of hydroxylamine by hæmoglobin is more complicated than was shown in the equation given by these workers and which was based on Letsche's observations[9]. In fact, the investigations by Lipschitz and Weber[10] and Roche[11] demonstrated that not only nitrogen, but also oxygen, ammonia and possibly nitrate are formed in the course of the catalytic oxidation of hydroxylamine by oxyhæmoglobin, the oxygen liberated from the latter being partly used in the oxidation reactions. Were Virtanen and Laine right in representing the formation of hydroxylamine as a part of a reversible equilibrium reaction of its decomposition by hæmoglobin, the production of hydroxylamine would require not only molecular nitrogen but also ammonia and possibly nitrate.

Conclusions

Our experiments clearly show that within the root nodules of leguminous plants hæmoglobin displays its usual property of oxygenation ($Hb + O_2 \rightleftharpoons HbO_2$). On direct spectroscopic examination, the nodules show only the mixture of hæmoglobin and oxyhæmoglobin. No methæmoglobin could be detected in nodules even if the plants were kept in the dark for several days. Neither experimental evidence nor general considerations support the view that the nitrogen fixation in root nodules involves a cyclical change of the valency of hæmoglobin iron. Moreover, it seems unlikely that oxido-reduction reactions in nodules are catalysed by a compound such as hæmoglobin, which has the remarkable property of oxygenation and is therefore an excellent oxygen carrier but a very inefficient catalyst. Although one cannot dismiss the possibility that under certain conditions hæmoglobin may act as an oxido-reduction catalyst, no evidence is so far available that this applies to hæmoglobin of root nodules.

On the other hand, the fact that this hæmoglobin is present in root nodules of every leguminous plant, that the pigment is formed only in nodules produced by an 'efficient' strain of *Rhizobium*, that the pigment is localized only within the large cells containing symbiotic organisms and that nitrogen fixation by nodules is strongly inhibited by small concentration of carbon monoxide, leave very little doubt that the activity of hæmoglobin is linked with the process of symbiotic nitrogen fixation. The presence of hæmoglobin in root nodules, therefore, will have to be taken into consideration in all further studies of nitrogen fixation by leguminous plants.

We are very grateful to Dr. H. G. Thornton for the strains 505 and 507 of *Rhizobium* used in this investigation.

PROCESSES INVOLVING CHARGED MESONS

By Dr. C. M. G. LATTES, H. MUIRHEAD, Dr. G. P. S. OCCHIALINI and Dr. C. F. POWELL

H. H. Wills Physical Laboratory, University of Bristol

IN recent investigations with the photographic method[1,2], it has been shown that slow charged particles of small mass, present as a component of the cosmic radiation at high altitudes, can enter nuclei and produce disintegrations with the emission of heavy particles. It is convenient to apply the term 'meson' to any particle with a mass intermediate between that of a proton and an electron. In continuing our experiments we have found evidence of mesons which, at the end of their range, produce secondary mesons. We have also observed transmutations in which slow mesons are ejected from disintegrating nuclei. Several features of these processes remain to be elucidated, but we present the following account of the experiments because the results appear to bear closely on the important problem of developing a satisfactory meson theory of nuclear forces.

In identifying the tracks of mesons we employ the method of grain-counting. The method allows us, in principle[3], to determine the mass of a particle which comes to the end of its range in the emulsion, provided that we are correct in assuming that its charge is of magnitude $|e|$. We define the 'grain-density' in a track as the number of grains per unit length of the trajectory. Knowing the range-energy curve fc the emulsion[4], we can make observations on th tracks of fast protons to determine a calibratio curve showing the relation between the grain-densit in a track and the rate of loss of energy of the particl producing it. With this curve, the observed distri bution of grains along the track of a meson allows u to deduce the total loss of energy of the particle i the emulsion. The energy taken in conjunction wit the observed range of the particle then gives a measur of its mass.

We have found that the above method give satisfactory results when, in test experiments, it applied to the determination of the mass of proton by observations on plates developed immediatel after exposure. The errors in the observed value based on grain-counts along individual tracks, a only a little greater than those corresponding to th statistical fluctuations associated with the finit number of grains in a track. As we have previousl emphasized, however, serious errors arise whe the method is applied to the plates exposed for sever weeks to the cosmic rays[3]. These errors are du mainly to the fading of the latent image in the tim elapsing between the passage of the particle and th development of the plate.

We have attempted to allow for fading by detern ining a calibration curve for each individual plat by grain-counts on the tracks of a number of proton chosen at random from those originating in 'stars Such a calibration curve corresponds to an averag value of the fading of the tracks in the plate. Whil we thus obtain improved mean values for the mas of particles of the same type, as shown[3] by tes measurements on the tracks of protons other tha those used in making the calibration, the individu values are subject to wide variations. In no cas however, have mass determinations by grain-coun of particles, judged to be protons from the frequenc of the small-angle scattering, given values exceedi 2,400 m_e or less than 1,300 m_e.

In these circumstances it is not possible to pla serious reliance on the masses of individual meso determined by grain-counts; and we employ t method, in the present experiments, only to disti guish the track of a meson from that of a proton. I searching a plate, an experienced observer quick learns to recognize the track of a meson by inspectio provided that its range in the emulsion excee 100μ. Nevertheless, we regard it as established th a particular track was produced by a meson only both the grain-density and the frequency of t Coulomb scattering correspond to the values chara teristic of a particle of small mass. We have co sidered the possibility that as a result of a rare co bination of circumstances we might, in spite of t above precautions, wrongly attribute the track of proton to a meson of mass less than 400 m_e. It difficult to give a numerical estimate of the pro ability of making such an error, but we believe it be very small.

Secondary Mesons

We have now made an analysis of the tracks sixty-five mesons which come to the end of the range in the emulsion. Of these, forty show evidence for the production of a secondary partic The remaining twenty-five lead to the production secondary particles. Fifteen of them produce d integrations with the emission of two or more hea particles, and from each of the remaining ten

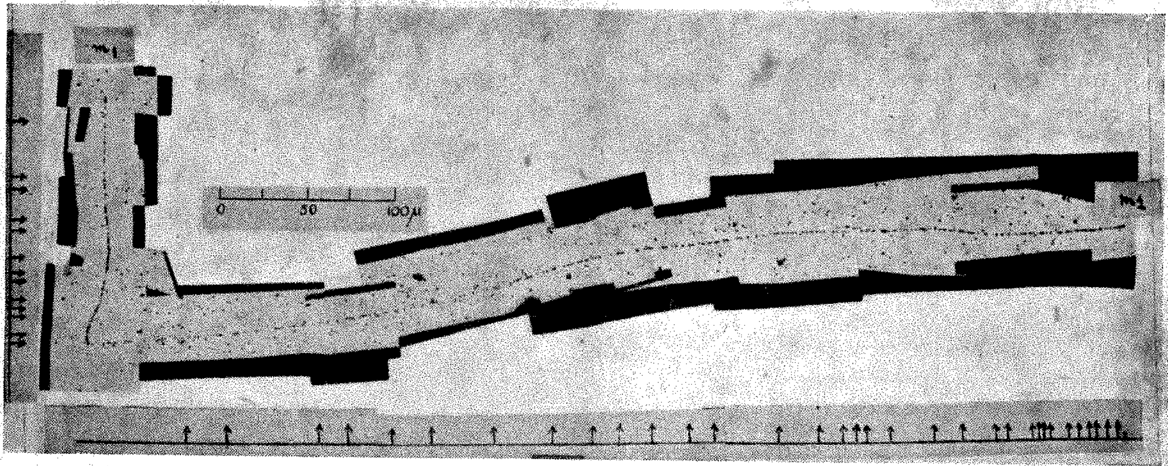

Fig. 1. OBSERVATION BY MRS. I. ROBERTS. PHOTOMICROGRAPH WITH COOKE × 45 'FLUORITE' OBJECTIVE. ILFORD 'NUCLEAR RESEARCH', BORON-LOADED $C2$ EMULSION. m_1 IS THE PRIMARY AND m_2 THE SECONDARY MESON. THE ARROWS, IN THIS AND THE FOLLOWING PHOTOGRAPHS, INDICATE POINTS WHERE CHANGES IN DIRECTION GREATER THAN 2° OCCUR, AS OBSERVED UNDER THE MICROSCOPE. ALL THE PHOTOGRAPHS ARE COMPLETELY UNRETOUCHED

observe a single secondary particle. Of these latter events, the secondary particle is in four cases a hydrogen or heavier nucleus; in four other cases the identification is uncertain, and in the last two cases it is a second meson.

Fig. 1 is a reproduction of a mosaic of photomicrographs which shows that a particle, m_1, has come to the end of its range in the emulsion. The frequent points of scattering and the rapid change of grain-density towards the end of the range show that the track was produced by a meson. It will be seen from the figure that the track of a second particle, m_2, starts from the point where the first one ends, and that the second track also has all the characteristics of that of a particle of small mass. A similar event is shown in Fig. 2. In each case the chance that the observation corresponds to a chance juxtaposition of two tracks from unrelated events is less than 1 in 10^9.

Grain-counts indicate that the masses of the primary particles in Figs. 1 and 2 are 350 ± 80 and $330 \pm 50\ m_e$, respectively; and of the secondary particle in Fig. 1, $330 \pm 50\ m_e$, the limits of error corresponding only to the standard deviations associated with the finite numbers of grains in the different tracks. All these values are deduced from calibration curves corresponding to an average value of the fading in the plate, and they will be too high if the track was produced late in the exposure, and too low if early. We may assume, however, that the two-component tracks in each event were produced in quick succession and were therefore subject to the same degree of fading. In these circumstances the measurements indicate that if there is a difference in mass between a primary and a secondary meson, it is unlikely that it is of magnitude greater than 100 m_e. The evidence provided by Fig. 2 is not so complete because the secondary particle passes out of the emulsion, but the variation in the grain density in the track indicates that it was then near the end of its range. We conclude that the secondary mesons were ejected with nearly equal energy.

We have attempted to interpret these two events in terms of an interaction of the primary meson with a nucleus in the emulsion which leads to the ejection of a second meson of the same mass as the first. Any reaction of the type represented by the equations

$$A_Z^N + \mu_{-1}^0 \rightarrow B_{Z-2}^N + \mu_{+1}^0 \text{ or } A_Z^N + \mu_{+1}^0 \rightarrow C_{Z+2}^N + \mu_{-1}^0, \quad (1)$$

in which A represents any stable nucleus known to be present in the emulsion, involves an absorption

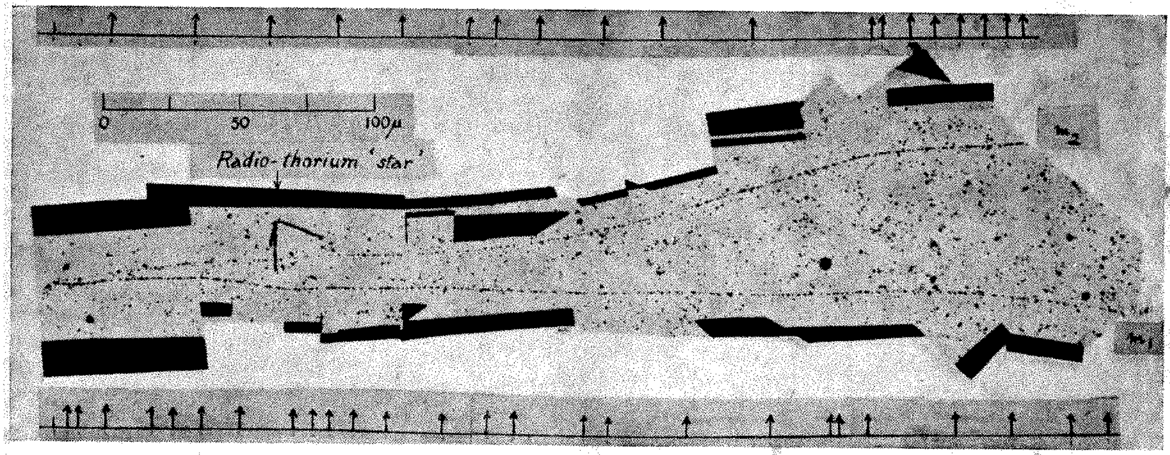

Fig. 2. OBSERVATION BY MISS M. KURZ. COOKE × 45 'FLUORITE' OBJECTIVE. ILFORD 'NUCLEAR RESEARCH' EMULSION, TYPE $C2$, BORON-LOADED. THE SECONDARY MESON, m_2, LEAVES THE EMULSION

of energy, in contradiction with the fact that the secondary meson is observed to have an energy of about 2 MeV.

A second process, represented by the equation

$$\mathrm{Ag}_{47} + \mu^{0}_{-1} \rightarrow X_{Z} + Y_{47-Z} + \mu^{0}_{+1}, \qquad (2)$$

in which X and Y represent two nuclei of approximately equal charge number, may be energetically possible, but the chance of it occurring in conditions where the total energy of the two recoiling nuclei is of the order of only a few million electron-volts is remote. It is therefore possible that our photographs indicate the existence of mesons of different mass[5,6,7]. The evidence provided by grain counts is not inconsistent with such an assumption. We have no direct evidence of the signs of the charges carried by the two mesons, except that the one secondary meson which comes to the end of its range in the emulsion does not lead to a disintegration with the emission of heavy particles. If, however, we assume that the transmutation corresponds to the interaction of the primary meson with a light nucleus, of a type represented by the equation

$$\mathrm{C}^{12}_{6} + \mu^{0}_{-1} \rightarrow \mathrm{Be}^{12}_{4} + \mu^{0}_{+1}, \qquad (3)$$

the difference in mass of the two mesons must be of the order of 60 m_e, according to estimates of the mass of the beryllium nucleus.

The only meson theory, to our knowledge, which assumes the existence of mesons of different mass is that of Schwinger[8]. It is visualized[9] that a negative vector meson should have a very short life and should lead to the production of a pseudo-scalar meson of the same charge but lower mass, together with a quantum of radiation. It will therefore be of great interest to determine whether the secondary meson, in transmutations of the type we have observed, is always emitted with the same energy. If this is so, we must assume that we are dealing with a more fundamental type of process than one involving particular nuclei such as is represented in equation (3). If, as an example of such a process, we assume that the momentum of the secondary meson appearing in our experiments is equal and opposite to that of an emitted photon, the total release of energy in the transmutation is of the order of 25 MeV.

In recent communications[10,11] very radical conclusions have been drawn from the results of observations on the delayed coincidences produced by positive and negative mesons in interactions with light and heavy nuclei[12,13]. It is assumed that a negative meson, at the end of its range, falls into a K orbit around a nucleus. In the case of a heavy nucleus, it is then captured, giving rise to a disintegration with the emission of heavy particles. With a light nucleus, on the other hand, it is regarded as suffering β-decay before being captured, so that like a positive meson, it can produce a delayed coincidence. The conclusion is drawn that the nuclear forces are smaller by several orders of magnitude than has been assumed hitherto. Since our observations indicate a new mode of decay of mesons, it is possible that they may contribute to the solution of these difficulties.

Emission of Mesons from Nuclei

Fig. 3 shows a mosaic of photomicrographs of a disintegration in which six tracks can be distinguished radiating from a common centre. The letters at the edge of the mosaic indicate whether a particular track passes out of the surface of the emulsion, *s* into the glass, *g*, or ends in the emulsion, *e*. The grain-density in tracks *a* and *c* indicate that the time between the occurrence of the disintegration and the development of the plate was sufficiently short to avoid serious fading of the latent image.

The track marked *f* suffers frequent changes in direction due to scattering, and there is a very rapid change in the grain-density in moving along the trajectory. These two features, taken together make it certain that the track was produced by light particle, and grain counts give an estimate fo the mass of 375 ± 70 m_e[14].

We have now observed a total of 1,600 disintegra tion 'stars', in each of which three or more charge particles are ejected from a nucleus. Of these, 17 correspond to the liberation of an amount of energ equal to, or greater than, that in the 'star' represente in Fig. 4, but only in two cases can we identify a

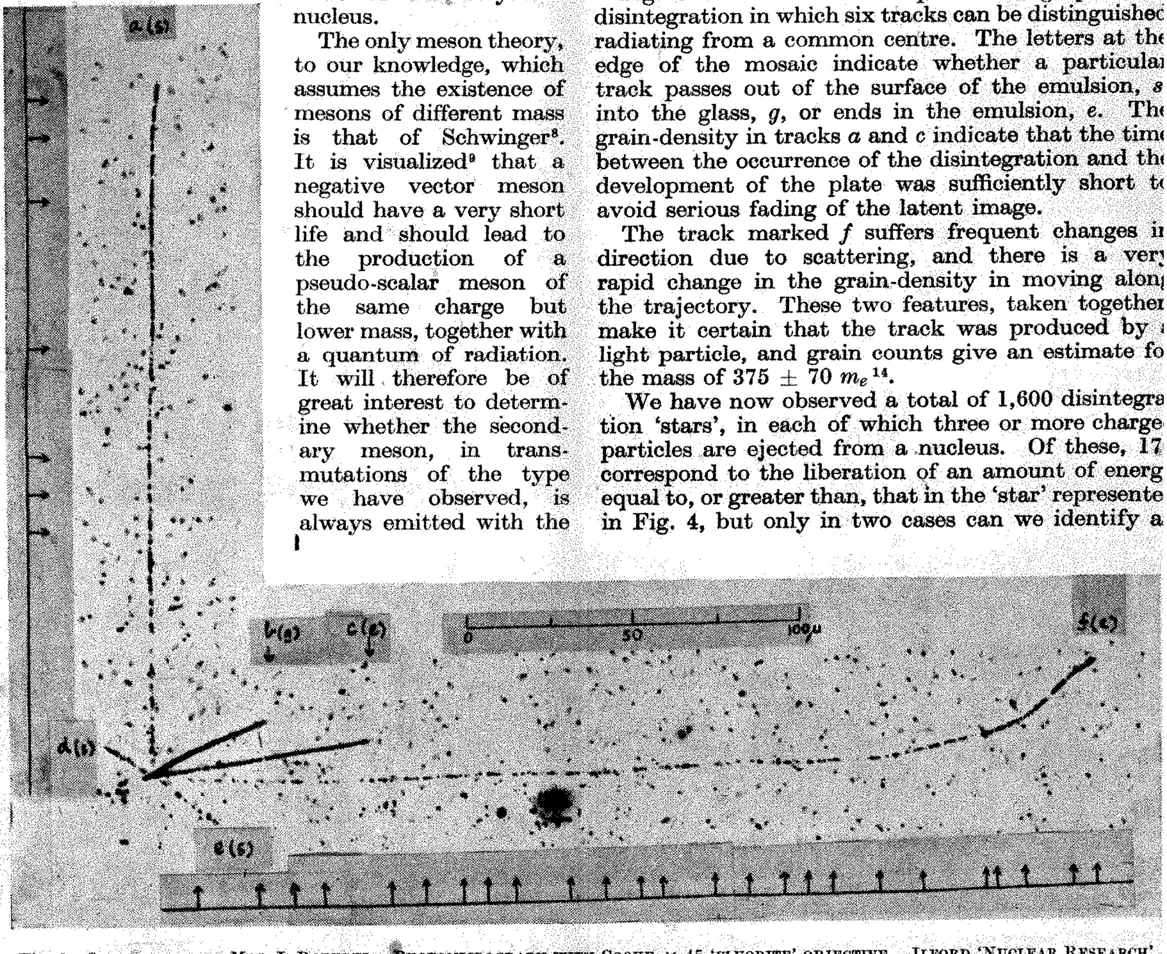

Fig. 3. OBSERVATION BY MRS. I. ROBERTS. PHOTOMICROGRAPH WITH COOKE × 45 'FLUORITE' OBJECTIVE. ILFORD 'NUCLEAR RESEARCH', BORON-LOADED C2 EMULSION. THE TRACK (*b*) DIPS STEEPLY AND ITS APPARENT GRAIN DENSITY IS GREATER THAN THE TRUE VALUE THROUGH FORESHORTENING. BOTH (*b*) AND (*c*) WERE PROBABLY PRODUCED BY α-PARTICLES

emitted particle as a meson. We cannot conclude, however, that the emission of mesons in such disintegrations is so rare as these figures suggest. If a meson is emitted with an energy greater than 5 MeV., it is likely to escape detection in the conditions of our experiments. Mr. D. H. Perkins, of the Imperial College of Science and Technology, has shown that, in the B_1 emulsion, the grain-density in the track of a meson becomes very small at energies greater than 2 MeV., and we must anticipate a similar result in the C_2 emulsion at higher energies. Our observations are therefore not inconsistent with the view that the ejection of mesons is a common feature of the disintegration of nuclei by primary particles of great energy, and that the present instance, in which the velocity of ejection has been exceptionally low so that an identification of the particle has been possible, is a rare example. It is possible that the example of meson production recently described[15] is due to a similar process, produced by a primary particle of higher energy, in which some of the heavier fragments emitted on the disintegration have escaped detection because of the depth inside the lead plate at which the event occurred.

The disintegration shown in Fig. 3 may be the representative of a type, common in the high atmosphere with particles of great energy. In the present instance the energy of the primary particle must have been of at least 200 MeV., and, if its mass was equal to or less than that of a proton, it would not have been recorded by the emulsion.

Disintegrations Produced by Mesons

The observation of the transmutations of nuclei by charged mesons has led to the suggestion of a method for determining the mass of these particles based on observations of the total energy released in the disintegration[1,2]. In attempting to apply the method, we meet the difficulty of identifying the particular type of nucleus undergoing disintegration and of taking account of any ejected neutrons which will not be recorded by the emulsion. A photograph of such a disintegration which, at first sight, appears to allow us to draw definite conclusions, is shown in Fig. 4. In the photograph, the tracks of four heavy particles can be distinguished, of which the short tracks α_1, α_2 and α_3 end in the emulsion; α_1 and α_2 were certainly produced by α-particles, and grain-counts show that α_3 is due to a proton. The observations are therefore consistent with the equation

$$N^{14}_{7} + \mu^{0}_{-1} \rightarrow 2He^{4}_{2} + H^{1}_{1} + H^{1}_{1} + 4n^{1}_{0}; \quad (4)$$

or, less probably, to a similar equation involving the emission of a deuteron or a triton in addition to the particles of short range.

Grain-counts on the track of the particle of long range, d, which passes out of the emulsion, indicate that if it was produced by a proton, the initial energy of the particle was about 15 MeV. Alternatively, if the particle was a deuteron, its energy was 30 MeV.; or, if a triton, 45 MeV. In any case, we can determine the minimum energy which must be attributed to the emitted neutrons if momentum is to be conserved in the disintegration. As a result, we find a minimum value for the mass of the primary meson of 240 m_e. The value determined by grain-counts is also 240 ± 50 m_e.

In view of the recent results of experiments on delayed coincidences, referred to previously[12,13], such results must, for the present, be accepted with great reserve. We must expect the liberation of an amount of energy of magnitude 100 MeV. in any nucleus to lead to the ejection of several particles, some of which may be neutrons. There is therefore no firm basis for assuming that the disintegration represented in Fig. 4 corresponds to the disintegration of a nucleus of nitrogen rather than one of silver or bromine. Indeed, the delayed coincidence experiments suggest that the second assumption is the more probable. When a sufficient number of observations with loaded plates has been accumulated, it may be possible to draw more definite conclusions from observed regularities in the modes of disintegration of particular types of nuclei.

A detailed account of the experiments will be published elsewhere.

UNIVERSITIES AND THE COMMUNITY

THAT public discussion on such a subject as "The Place of Universities in the Community" would range over a wide field was to be expected, and the one-day conference on that subject arranged by the British Association on May 10 at the University of Manchester proved no exception. The immediate purpose of the conference, to discuss important problems arising out of the projected expansion of the universities of Great Britain, tended at times to be overlooked by those who took part in the discussions at both sessions, and while the conference made some contribution to the education of public opinion as to what is involved in the expansion of the universities, particularly on the scientific side, little was added to what has already emerged in the debate between men of science and others on these questions, both before and after the appearance of the Barlow Report.

The first of the two sessions was devoted specifically to the consideration of the implications of the Barlow Report. Lord Simon of Wythenshawe, who presided over this session, did his best to keep the discussion on realistic lines but contented himself in his opening remarks with presenting the administrative background to the Barlow Report, pointing out that it was only one of a number of such official reports dealing with the question of capacity of the universities to provide the trained men and women which the community requires. He referred specifically to the earlier Goodenough, Teviot, McNair and Clapham Reports, and to the more recent Scarborough Report; but in view of what was said later by Prof. M. Polanyi, he might well also have cited the earlier Barlow Report on scientific staff. Lord Simon then quoted from the "Note on University Policy and Finance in the Decennium 1947–56" (which was discussed in *Nature* of April 12, p. 483), and emphasized the acceptance by the universities of the view that the Government has the right and the duty to satisfy itself that every field of study which in the national interest ought to be cultivated in Great Britain is in fact being adequately cultivated in the universities, and that the universities are using their resources with full regard both to efficiency and to economy. If the universities are collectively to devise and execute policies calculated to serve the national interest, the University Grants Committee would require strengthening, and Lord Simon referred to the recent appointment of a whole-time deputy chairman and to the Chancellor of the Exchequer's indication of the ultimate expansion of the grant to the universities to be administered by the Committee to at least £16–£20 millions as against £2–£4 millions before the War.

These figures were probably less effective in indicating what is immediately involved than Lord Simon's incidental remark that doubling the output of scientific workers within five years is a rate of expansion much greater than has ever been contemplated in the United States. The administrative and financial aspects were, however, scarcely again considered in the discussion. Prof. P. M. S. Blackett, who followed, thought that sufficient talent is available to provide the increased number of scientific workers required, and referred in particular to the reserve demand for such trained individuals represented by the teaching profession and by private industry, which probably needs more men of science than it recognizes. He urged that the Barlow Report should be followed by a further statistical inquiry into both the sources from which students enter the universities and the future of the graduates when they leave them.

One at least of these lines of thought was pursued by Dr. Eric James, high master of the Manchester Grammar School, who urged that the great weakness of the Barlow Report is that no evidence was taken from the schools as to their capacity to provide the requisite number of potential science graduates. He thought that the report made insufficient allowance for the number of trained science teachers required in the schools, on the quality of whose work in the schools, he maintained, the work of the universities rests. He urged that it should be a priority of the first order to discover where in the educational ladder the wastage of intelligence and talent occurs; emphasizing that we should remember that the educational system is a whole and not consider the universities apart from the schools, he pointed out that so far we have failed to formulate in any specific terms our ideas as to a general education for scientific workers.

This plea was later taken up by Sir John Lennard-Jones. He urged that, as providing a link between the nation's intelligence and public affairs, the university has a duty to the State and should make a point of being fully and accurately informed as to the nation's need for trained workers, and moved a resolution which was seconded by Prof. J. D. Bernal and adopted at the end of the session. The resolution recommended to the Council of the British Association that the University Grants Committee be invited, in collaboration with the universities, (1) to make extensive factual surveys of the openings for graduates in the national life; (2) to maintain records of the careers of university graduates and the measure of their success in their professions; and (3) to publish periodic reports of the results of such surveys for the guidance of universities and schools. Whatever reservation individuals may have felt about the wisdom of asking the University Grants Committee to undertake this task—and misgivings were expressed in private if not publicly—the importance of university co-operation in appointments work was fully recognized, although no one pointed out that the Hankey Committee has already recommended that this work should be undertaken by the Higher Appointments Department of the Ministry of Labour.

Other points raised in the morning discussion were the age at which choice of a scientific career is usually determined, the detrimental effect of existing overcrowding and of the shortage of teaching staff. The importance of careful selection of students in university expansion and of encouraging adaptability and discouraging the intensive specialization which hinder mobility were noted. Mr. Ritchie Calder, commenting on the danger of middle-class unemployment, urged that greater emphasis should be placed on the regional character of the university; a position in which only 10 per cent of science graduates from Scottish universities find employment in Scotland is most unsatisfactory.

Opening the second session of the conference, which was to consider more specifically research and organisation, Sir Henry Dale, who presided, suggested that with the universities dependent on the Government for more than seventy-five per cent of their income, the influence of Government departments might become a serious factor in the expenditure of funds on research. Sir Henry Dale voiced once more the fears that he has often expressed that the war-time practice of the universities of carrying out research on subjects laid down by outside authorities might be perpetuated. He emphasized the vital importance of the universities maintaining, in Britain and elsewhere, their full independence, and reiterated that the proper function of the universities is to promote free research with no immediate objectives but to widen the boundaries of knowledge, in contradistinction to prescribed research undertaken for the particular end of solving an immediate practical problem.

No evidence was given during the meeting that either industry or the Government is offering research endowments to the universities to which restrictive or secrecy conditions are attached, and it is noteworthy that all recent reports on research and the universities which have recognized the increasing dependence of the universities on Government financial support have been confident of the ability of the universities to maintain their independence. Nevertheless, the afternoon session adopted the resolution moved by Sir Henry Dale recommending the Council of the British Association to make representations to the competent authorities of all universities in the British Empire, urging that under the normal conditions of peace no contract for research should be accepted by the scientific departments of any of these universities if its terms included any restriction on freedom of publication.

In their plea for a follow-up of the Barlow Report by an investigation of the educational ladder at the school stage, Prof. Blackett and Dr. James introduced the first new distinctive note; Prof. M. Polanyi struck the second. In a paper on the organisation of universities, without pursuing the secrecy theme, Prof. Polanyi spoke strongly for the universities as the natural nurseries and homes of fundamental research. He recognizes the twin relations of teaching and research, and he pleaded that the advancement of learning depends on the universities being maintained as the well-springs of discovery. As Sir Henry Dale had said, it is the function of the university to hold aloft the search for truth in all its aspects; but when Prof. Polanyi added that it is waste of time to endow academic research workers unless the recipients are left free to use the funds at their own discretion, he gave expression to a principle which might well be re-considered by those industrial firms who have, as he indicated, tended to enter the academic field. Doubtless the distinction may not always be easy to maintain, but Prof. Polanyi equally insisted that the university itself should be careful not to be tempted into the investigation of practical problems which lie outside its own experience.

This most significant passage in Prof. Polanyi's paper was rather overlooked in the discussion, which seized, first on his reference to the importance of refusing to fill vacancies in senior appointments with men or women below a certain level of distinction, and of not regarding too closely the special field of inquiry, even if this involves some over-crowded departments and others with chairs vacant indefinitely; and secondly, on his defence of some disparity between academic salaries and those of other professional positions in industry or elsewhere. Prof. Polanyi also maintained that unless society appreciates science for its own sake, it will not continue for long to cultivate genuine scientific research, and accordingly in the long run the universities depend for their existence on the recognition of cultural obligations by the nation. He also insisted that since it is impossible to recognize and subsidize all the growing points of science, the universities, which uphold the broad principle that their task is to supply individual creative minds with the opportunities to do the work of their own choice, cannot agree with the Vice-Chancellor's Committee that it is their function to plan to meet the whole range of national need for higher teaching and research.

Prof. Bernal did not altogether follow Prof. Polanyi in this view. His discussion of research was obviously coloured by his recent experience of war-time conditions, and he distinguished research as of two types: subjective research, which he agreed should be left to the universities, and the objective and prescribed research, distinguished by Sir Henry Dale. While subjective research is the proper function of the universities, Prof. Bernal insisted that the greater need is for a new type of research worker and director able to integrate this with other activities. He urged that social and economic problems can likewise be tackled on scientific lines; here he was obviously less concerned with the creative aspect and the freedom of choice stressed by Prof. Polanyi than with the question of organisation and the fact that the individual scientific worker might exercise his choice without adequate knowledge. He supported both the regional work of the university—regional contacts, he believes, will help to suggest continually fruitful problems for investigation by the universities, which should make it their business to discover the needs and problems of the region—and the cultural value of scientific research. We need a unitary culture which to-day must contain a scientific method, just as the experimental method would play a part in uniting knowledge. If an adequate social philosophy is not yet fully formed, we have at least learned that the whole approach to social problems as well as to physical problems should be scientific.

In a somewhat rambling discussion, little was said which had not already been ventilated in previous reports on the universities and research. Some points in that from the Association of Scientific Workers in particular were mentioned. The claims of social science as presented in the Clapham Report, and also of adult education, on the support of the universities were also emphasized. Dr. C. H. Desch referred to the changing outlook in the steel industry and to the demand for scientific workers for research and management positions in contrast to a demand merely for testing work, and to the way in which patents policy offsets the obsolete tendency to secrecy in industrial research. Commenting on the need for providing for the new growing points in science, Prof. Polanyi's suggestion that chairs should be left vacant found some support, Dr. Gordon observing that the universities should make it clear to the Government beforehand that they do not propose to retain inferior men in professorial chairs even if appointed on trial. His comment about differentiation in salary scales, however, was challenged; Prof. Polanyi had not denied that university salaries are in need of revision upwards; the scientific worker in a university should be remunerated on a scale which permits him to maintain a family.

OBITUARIES

Prof. V. M. Goldschmidt, For.Mem.R.S.

Victor Moritz Goldschmidt, the eminent geochemist, formerly professor of mineralogy and geology in the University of Oslo, died on March 20.

He was born in Zurich in 1888, the son of H. J. Goldschmidt, who became professor of chemistry at Oslo in 1900. He entered the University of Oslo in 1905, taking as his main subjects chemistry, mineralogy and geology, and there came under the inspiring influence of Prof. W. C. Brögger, whom he was eventually to succeed. He was appointed professor and director of the Oslo Mineralogical Institute in 1914 at the early age of twenty-six. A highly successful teacher, he founded a large research school both at Oslo and at Göttingen, where he moved in succession to Mügge in 1928. Many of his former pupils now hold professorships or high posts in industry, in Europe or America.

Goldschmidt resigned the Göttingen chair in 1935 as a protest against the Hitler regime, and returned to Norway. In 1942 he was sent to a concentration camp by the Germans and sentenced to deportation to Poland, but escaped to Sweden and offered his services to the Allies. He came to Britain in the spring of 1943 and worked under the auspices of the Agricultural Research Council; the first year he spent at the Macaulay Institute for Soil Research, Aberdeen, and later went to Rothamsted Experimental Station, where he remained until his return to Oslo in 1946. For some of the particulars of this notice I am indebted to Dr. W. G. Ogg of Rothamsted and to Dr. R. C. Evans at Cambridge.

Goldschmidt's researches divide themselves broadly into an early group of studies (1911–20) devoted chiefly to petrology and geology; the main group of fundamental geochemical investigations which followed from 1920; and the pioneer crystallochemical studies (1925–27) which developed naturally from them and in turn served to interpret his later work.

His researches in the field of rock metamorphism have been of the first importance. The study he made of the metamorphic aureoles around the igneous massifs of the Oslo district marked a major advance in the correlation of the chemical and mineralogical composition of thermally reconstituted rocks, and contained the first successful essay towards a systematic classification of rock mineral assemblages in the light of the phase rule. Equally important were his investigations on the zonal metamorphism of the crystalline schists of the Palæozoic mountain region of southern Norway, forming as they did a genetic study of rocks re-crystallized under shearing stress and high temperature developed during regional folding and igneous injection.

Goldschmidt's researches in geochemistry were initiated during the First World War when the deficiency of raw materials led him to extended investigations on the mineral resources of Norway. The organisation of this research was entrusted to him by the Norwegian Government in 1917, and he became chairman of the Commission for Raw Materials and director of the Raw Materials Laboratory.

After the War, with a keen research team, he applied himself with great energy to the study of the basic problem of geochemistry—the discovery of the general laws and principles governing the distribution of the chemical elements in Nature. To this end both old and new methods of chemical and physical analysis were brought to bear on the investigation of rocks and minerals. X-ray analysis and quantitative spectrographic methods provided new lines of attack, and he developed later, particularly at Göttingen, an improved technique of carbon arc spectrography.

These studies led directly to his work in crystal chemistry, the most important of his results in this field appearing in the brilliant group of memoirs published in 1925–27: "Geochemische Verteilungsgesetze der Elemente" (iv–viii). His researches on the crystal structure of ionic compounds may indeed be regarded as laying the foundation of the science of crystal chemistry. By the systematic investigation of a wide range of compounds, he was able to formulate the picture of an ionic structure as being determined primarily by the geometrical packing of ions of characteristic sizes, and to tabulate for the first time values of ionic radii for the majority of the elements. These data in their turn provided a basis for the understanding of the problems of morphotropy, and led to an explanation of the morphological relationships which exist within groups of closely related compounds and to a correlation between physical properties and crystal structure.

The principles which Goldschmidt thus established were afterwards codified more formally but without essential modification by Pauling, and have been tacitly invoked in all later work on the X-ray study of ionic structures.

The elaborate series of geochemical investigations Goldschmidt began at Oslo and continued at Göttingen have revolutionized our knowledge of the distribution of the minor constituents of the earth's crust. He demonstrated the partition of a large number of the rarer elements among the successive products of the geological cycle—from the primitive magma to the sediments and the sea—and showed that ionic size and charge are important factors controlling their ultimate sorting and concentration.

Goldschmidt's industrial work was also of great importance. He was a pioneer in the development of forsterite as a commercial refractory, now in wide use; he worked out a process for making alumina from labradorite felspar, and took part in the development of titanium pigments. His interest in agriculture arose during the First World War when Norway was faced with a shortage of potash fertilizers. He suggested the possibility of using biotite as a source of potash, and though the idea was not altogether new, the resulting experiments he developed are probably the most complete set carried out to test the possibilities.

At Göttingen in connexion with his studies of trace elements, he and his colleagues examined samples of soil and tree leaves and showed the marked relative accumulation of certain trace elements in forest litter. What was probably his last publication was an article introducing a trace element symposium in *Soil Science*.

During his stay at the Macaulay Institute and at Rothamsted, Goldschmidt was generous with his advice and took a great interest in the work of trace-element distribution.

He had for some years been engaged on a comprehensive treatise on geochemistry. It is known that the greater part of this was written before he left England, and it is confidently expected that he was able to complete it for eventual publication.

C. E. Tilley

I wish to add to Prof. Tilley's account a few recollections of my personal relations with V. M. Goldschmidt. When he first came to Göttingen there was a latent tension between us, a mutual doubt regarding our work on ionic crystals: he considered my calculations of lattice energies cumbersome and scarcely worth while, and I had no confidence in his primitive way of adding ionic radii. But we soon discovered that these two methods were complementary, one providing exact values in a few simple cases, the other covering the whole field of crystal chemistry. After clearing the air, we became great friends. He was a remarkable man in many respects. His memory was stupendous. Once I sent an assistant to him to ask about literature on a great number of data. Instead of giving the titles of papers, he just dictated the numerical tables from memory, and a later check proved them essentially correct. He knew by heart not only the properties of atoms and ions, like radii, polarizabilities, etc., but also their occurrence in minerals and the distribution of these minerals in the earth's crust. If he did not know a fact, he had simple ways of deriving it from his radii.

Goldschmidt had a very original mind and a great sense of humour which sometimes found expression in a somewhat caustic manner. One had to take the trouble to look below the surface to discover a gentle and most generous nature which was easily wounded, and had no other defence than to hit out. To those who came to understand this, he was a devoted and most loyal friend, and they now mourn for one who has enriched their lives. M. Born

Prof. Ludwig Jost, For.Mem.R.S.

By the death on February 22 of Prof. Ludwig Jost, Germany has lost one of its most respected botanists and science one of the leading plant physiologists. Born in 1865 at Karlsruhe, he was educated at the local *Gymnasium*. In the autumn of 1883 he commenced his studies at the University of Heidelberg, attending particularly the lectures of Bütchli and Pfitzer. Afterwards he moved to Strassburg to study under de Bary. In 1887 he took his doctor's degree there, presenting a thesis on the breathing roots of palms. In the same year he was appointed assistant to Prof. Goebel in Marburg, and later returned to Strassburg, where he acted as assistant first to de Bary and after the death of the latter to Count Solms Laubach. In 1894 he was appointed assistant professor, and in 1907 to a full professorship in the University of Strassburg. In 1919, when the French re-entered that town, he had to leave, but was lucky enough to get an appointment to the vacant professorship at Heidelberg, which he held until his retirement in 1934. He was then elected emeritus professor and continued his scientific work privately in the Kaiser Wilhelm Institute at Heidelberg, where he died, having been failing in health for some years. He was always strongly averse to the Nazi regime, and his sufferings were accentuated by the poor nutrition since the end of the War.

His varied training as a student had given him a wide outlook in botany, and his own researches touched the fields of morphology as well as those of physiology. The first edition of his lectures on plant physiology appeared in 1904 and was sufficiently appreciated to be followed by three further editions.

He won for himself a considerable reputation both at home and abroad and was elected a foreign member both of the Royal Society and the Linnean Society. His personal kindliness and his unassuming manner endeared him to all with whom he came in contact. F. E. Weiss

We regret to announce the following deaths:

Sir Thomas Holland, K.C.S.I., K.C.I.E., F.R.S., principal and vice-chancellor of the University of Edinburgh during 1929–44, on May 15, aged seventy-eight.

Sir Frederick Gowland Hopkins, O.M., F.R.S., president during 1930–35 of the Royal Society, on May 16, aged eighty-five.

NEWS and VIEWS

Prof. E. Cartan, For.Mem.R.S.

Prof. Elie Cartan, who has just been elected a foreign member of the Royal Society, has been in the forefront of French mathematics since 1894, when his doctorate thesis on the structure of continuous groups was first published. In response to continued demand, it was reprinted forty years later. This subject has been Cartan's chief interest throughout his subsequent career as a mathematician. By 1900 Cartan had made fundamental contributions in another field, the problem of Pfaff. Two long memoirs on the subject appeared about this time in the *Annales de l'Ecole Normale*. It was in the first of these (in 1899) that he developed systematically the theory of 'exterior differential forms' which obey the laws of exterior multiplication of Grassmann. Throughout most of his subsequent work Cartan has found the method of 'exterior derivation' an extremely powerful one.

Cartan's chief contributions to the theory of relativity appeared between the years 1922 and 1925 when a systematic study of the gravitational equations of Einstein in the *Journal de Mathématique* was followed by a series of papers on relativity theory and affinely related spaces in the *Annales de l'Ecole Normale*. These last may be said to mark the beginnings of his major contributions to differential geometry, where he has found the method of the moving trihedron (*repère mobile*) of dominant significance. The essential unity of Cartan's ideas in different branches of mathematics is well illustrated by a tract which he published in the "Actualités" series in 1935, in which he shows that the theory of the moving trihedron has an intimate connexion with the equations of structure of a continuous group, and that the equations of structure of a group G contain in themselves all the differential geometry of the space having G as fundamental group.

Organic Chemistry at Edinburgh: Prof. E. L. Hirst, F.R.S.

Prof. E. L. Hirst, at present Sir Samuel Hall professor and director of the Chemical Laboratories in the University of Manchester, has been appointed to the newly instituted Forbes chair of organic chemistry in the University of Edinburgh. Prof.

Hirst, who was born in 1898, was educated at the Northgate School, Ipswich, and Madras College, St. Andrews. After graduating M.A. in Latin, Greek and logic at the University of St. Andrews, Hirst proceeded there to the degrees of B.Sc. and Ph.D. in chemistry under Prof. (later Sir) J. C. Irvine. While at St. Andrews he made notable contributions to the chemistry of cellulose and the structure of simple sugars. He was an assistant in chemistry at St. Andrews during the brief professoriate of (Sir) Robert Robinson, and moved with him to Manchester. In 1924 Hirst was appointed lecturer in Armstrong College, University of Durham, where Prof. (now Sir) Norman Haworth, with whom he had worked in St. Andrews, had established a school of carbohydrate chemistry. Haworth was appointed to Birmingham in 1925, and in the following year Hirst followed him; Hirst was appointed reader in the chemistry of natural products in 1935. This period marked a tremendous advance in carbohydrate chemistry, when the ring forms of sugar and glycosides were given precise definition, the constitution of all the important disaccharides was established, and great advances in the chemistry of starch, glycogen and cellulose were made. Hirst's most spectacular work at this time was the determination of the constitution of ascorbic acid (vitamin C) and its synthesis (in association with Haworth), representing the first laboratory synthesis of a vitamin.

In 1936, Prof. Hirst was elected Alfred Capper Pass professor of chemistry in the University of Bristol; here he continued and extended his studies on carbohydrates to such highly complex bodies as pectins, plant gums and mucilages, and threw further light on the constitution of starch. This work was interrupted during the recent War, when all academic research at Bristol was discontinued. Hirst was appointed head of the Bristol Outstation Armament Research Department. He served on the Scientific Advisory Committee of Research and Development of the Ministry of Supply, and was chairman of the Explosives Committee (Chemistry) and of various panels during the period of hostilities. Since Prof. Hirst's appointment to the Manchester chair in 1944, his work has been mainly concerned with the development of new methods for end-group determinations for use in dealing with the problems of the structure of complex polysaccharides. Hirst served as an independent member of the Working Party for the Cotton Industry, and was chairman of its research sub-committee.

Dr. K. Mellanby, O.B.E.

DR. K. MELLANBY, who has been announced as principal designate of the new University College which it is proposed to establish in Nigeria, has had a varied career. Trained at Cambridge as a zoologist, he devoted himself in the years before the War to the study of insect physiology. First, at the London School of Hygiene and Tropical Medicine and in Uganda he did illuminating work on the water relations of insects. As Sorby Research Fellow of the Royal Society he transferred to Sheffield and studied particularly the adaptation of insects to cold, both in the laboratory and in the field—in arctic Finland. At the outbreak of the War, Dr. Mellanby's organising ability became apparent. A survey of the incidence of head-lice among children in fever hospitals throughout the country gave the first accurate picture of the distribution of pediculosis in Britain. Dr. Mellanby then turned to the scabies problem. Enlisting the co-operation of a team of 'conscientious objectors' to serve as experimental subjects, he was able to carry out a fine scientific and practical study of scabies which placed our knowledge of the incidence and spread of the itch mite and the efficacy of the various treatments on a really sound basis. The well-known film of this work was a valuable piece of propaganda.

After a period as scientific liaison officer in North Africa, Dr. Mellanby joined the team organised by the Medical Research Council to investigate the spread of scrub typhus. His particular province was the ecology of the mites which carry the disease; but he again put great energy into the propaganda side of the work, including the preparation of an instructional film. Extensive travel in America, Australia and the Pacific area provided more valuable experience. In 1945 he was appointed reader in entomology at the London School of Hygiene and Tropical Medicine. Dr. Mellanby's wide knowledge of the world, his organising ability and a gift for getting on well with all sorts of people promise success to this new venture.

Government Estimates for Scientific and Industrial Research

THE Civil Estimates for the year ending March 31, 1948, now published (Class VI) show a gross estimate of £3,449,375 for the Department of Scientific and Industrial Research, against which appropriations in aid amount to £331,086, the net increase on 1946–47 being £727,355. Grants for investigation and research are estimated at £1,182,000, an increase of £254,400 on 1946–47, of which £842,000 is represented by annual grants to research associations and bodies engaged in industrial research, and £240,000 by grants to students and other persons or bodies engaged in scientific research. Headquarters expenditure is estimated at £175,780 as against £129,604 in 1946–47, and the estimate for the National Physical Laboratory shows an increase from £423,180 to £489,459, with an increase in staff from 611 to 731. The estimate for the Chemical Research Laboratory is increased from £42,158 in 1946–47 to £57,753, with an increase in staff from 58 to 102. Expenditure on the Building Research Station is estimated at £192,390 as against £151,380, with an increase in staff from 255 to 374; on food investigation at £88,803 as against £78,365, with an increase from 111 to 136 in staff; on the Forest Products Research Laboratory at £69,929 as against £61,913, with an increase in staff from 77 to 112; on fuel research at £164,676, as against £137,340, with an increase in staff from 174 to 232; on the Pest Infestation Laboratory at £22,444 as against £19,386, with an increase in staff from 43 to 52; on the Road Research Laboratory at £152,929 as against £97,850, with an increase in staff from 147 to 233; and on the Water Pollution Research Laboratory at £29,754 as against £22,058, with an increase in staff from 51 to 74. The total staff is estimated at 2,129 as against 1,538 in 1946–47. For the Geological Survey and Museum of Practical Geology, expenditure is estimated at £187,704 as against £106,941.

This net total of £3,118,289 represents only a part of the Treasury contribution to research for the current year. In addition to the vote of £12,000,000 to the universities, part of which at least will be expenditure on research, the Civil Estimates include appropriations of £698,000 for the Medical Research Council, £400,000 for the Agricultural Research

Council, £1,977,450 for agricultural education and research under the Ministry of Agriculture and Fisheries, and £412,652 for agricultural research and experiments under the Department of Agriculture for Scotland; £144,450 for fisheries research, £374,000 for forestry research and education, £78,623 for fisheries research and development in Scotland, £500,000 for Colonial research, and £50,000 for the social survey. Miscellaneous grants in aid of scientific investigation include £53,000 to the Royal Society. The grand total is approximately £19,500,000. Although the Dominions Office vote includes a grant of £33,825 in aid of Imperial Economic and Research Services, and the Ministry of Food vote £4,500,000 for the production of ground-nuts in East and Central Africa, of which some small fraction is for research, it is unlikely that the total expenditure from the Exchequer in aid of civil research much exceeds £10,000,000 for the current year as against the £60,000,000 to be expended by the Ministry of Supply and the Admiralty, apart from the work which may be carried out by the Department of Scientific and Industrial Research for the Services.

Atomic Power in Sweden

THE Swedish Atomic Committee, which consists of ten leading men of science and technicians, has submitted a proposal to the Swedish Government, recommending the formation as soon as possible of a joint-stock company, AB Atomenergi, with a capital of about £241,000, of which about two thirds would be contributed by the State and the remainder by Swedish industry. The first task of the company would be to design and build an experimental plant for the liberation of atomic energy, and later on a plant for the production of atomic power on an industrial scale would be erected. The Committee also suggests that, in addition to 2,000,000 kronor already proposed in the current State budget, another 2,000,000 kronor should be appropriated for research work to be performed under the supervision of a new body, the Atomic Research Council. It is reported that the company will use uranium from shale deposits in the central Swedish provinces of Närke and Västergötland.

Suggested British Herpetological Society

AT an informal meeting held at the British Museum (Natural History) on April 10 the formation of a British Herpetological Society was considered. The Society would be formed with the view of increasing our present knowledge and promoting interest in various aspects of herpetology which, it is felt, have been somewhat neglected. Its main objects would be: (1) to encourage the study of the ecology, life-histories, habits and distribution of the Amphibia and reptiles, and of the British species in particular; (2) to publish annually a report on the work of the Society, and to review briefly advances in knowledge, particularly in the field of ecology; (3) to hold meetings, when possible, for the reading of papers and the discussion of problems relating to herpetology; (4) to record and compile information on the various aspects of the subject covered by the Society. Although such a Society would, of necessity, be concerned mainly with the study of British species, foreign membership would be most welcome. It is suggested that the annual subscription to the Society, including a free copy of the report, should be ten shillings. Those interested in the formation of such a Society should communicate with Capt. J. D. Romer, 96 Mortlake Road, Kew, Surrey. If the response is sufficiently large, further steps will be taken to inaugurate the Society, and individuals will be informed accordingly.

Association of Social Anthropologists

AN Association of Social Anthropologists was founded on July 23, 1946, in response to the general opinion among social anthropologists in Great Britain that the subject has reached a stage of development warranting the establishment of a professional organisation. Its objects are to promote the study and teaching of social anthropology as a specialized branch of anthropology; to represent the interests and maintain the professional standards of the subject; to arrange periodic conferences of the members of the Association; and to secure publication of researches under its auspices. It is intended to publish a journal, *Annals of Social Anthropology*, as soon as arrangements can be made.

The Association includes teachers and senior research workers in social anthropology in the British Empire. Membership is limited to persons holding, or having held, a teaching or research appointment in social anthropology, and is strictly by invitation of the officers and committee of the Association. The present officers and committee are: Prof. A. R. Radcliffe-Brown (president), Prof. E. E. Evans-Pritchard (chairman and hon. secretary), Prof. Raymond Firth, Prof. C. Daryll Forde and Dr. Meyer Fortes.

Iraq Natural History Museum

THE first Natural History Museum in Iraq, which is under the auspices of the Iraqi Ministry of Education, was established early in 1946. The formal opening by the Regent of Iraq took place on May 2, 1946. The Museum consists of three main departments at present. (1) Zoological Department: the present exhibits in this department represent most of the avifauna of Iraq, as well as small collections of Iraqi mammals, reptiles, fishes and invertebrates. (2) Botanical Department: in this department plaster models of Iraqi fruits and vegetables are exhibited. There are also specimens of plant products, economic plants, plant diseases, etc. (3) Geological Department: in this department two of the oil companies operating in the country have participated in presenting its exhibits. The Iraq Petroleum Co. presented a cement model of the geological structure of the Kirkuk oilfields, as well as specimens of rocks, crude oil, and fossils found in Iraq. The Rafidain Oil Co. presented a model of an oil refinery, specimens of oil products, a model of a Leyland motor oil-tanker, a lubricating oil unit, a petrol filling pump, and various photographs and diagrams. The Museum is seeking to establish contacts with similar museums elsewhere, and to exchange information and publications with them. All communications should be addressed to the Director, Iraq Natural History Museum, Baghdad, Iraq.

British Society for the History of Science

AT the first annual general meeting of the British Society for the History of Science, held in the rooms of the Royal Society on May 5, the following elections of officers and council were made: *President*, Dr. Charles Singer; *Vice-Presidents*, Prof. H. Dingle, Dr. E. J. Holmyard, Sir Arthur MacNalty, Prof. J. R. Partington, Mrs. Charles Singer, Dr. Sherwood

Taylor; *Hon. Secretary*, F. H. C. Butler; *Hon. Treasurer*, H. W. Robinson; *Council*, Dr. H. P. Bayon, Prof. G. R. de Beer, C. N. Bromehead, J. G. Crowther, Dr. Dorothy Feyer, Dr. S. Lilley, Dr. D. McKie, H. T. Pledge, Dr. H. Shaw, Dr. H. Hamshaw Thomas, Sir Henry Thomas and Dr. E. Ashworth Underwood. The address of the honorary secretary is: Ravensmead, Keston, Kent.

Colonial Medical Research Studentships

On the recommendation of the Colonial Medical Research Committee, the Secretary of State for the Colonies has instituted ten research studentships for graduates in medicine and cognate sciences, who desire by this means to prepare themselves for research work in tropical medicine and related subjects. The Studentships will carry an allowance at the rate of £260 per annum, and will normally be for a period of two years. They will be awarded on the advice of the Colonial Medical Research Committee, and will be tenable at any university or other appropriate institution as approved by the Committee. Candidates must be British subjects and graduates of British universities. Application should be made, through the head of the candidate's department, to the Secretary, Colonial Medical Research Committee, c/o Research Department, Colonial Office, London, S.W.1.

Textile Institute

The Textile Institute is offering a scholarship, under the terms of a grant from the Cotton Trade War Memorial Fund, to young craftsmen in the cotton spinning or weaving industry, and is planning an additional award for those who have not yet entered the industry. The scholarship will extend for not more than three years, and is of a maximum value of £200 prior to the final year, and £350 for the final year, during which it will provide the holder with practical experience abroad. Forms of application can be obtained from the General Secretary, Textile Institute, 16 St. Mary's Parsonage, Manchester 3; applications are to be made by July 1.

Prof. Fred Bradbury, formerly head of the Department of Textile Industries at Belfast College of Technology, has been elected to honorary life membership of the Textile Institute. Prof. Bradbury took part in the formation of the Institute thirty-seven years ago, and was a member of the Institute's first Council elected in 1910.

Congresses

International Congress on Short-Wave Therapeutics

An International Congress on Short-Wave Therapeutics will be held in Amsterdam during July 19–24, 1948. Formal papers followed by discussions are being arranged. Particulars can be obtained from the Secretary of the Congress, Weteringschans 73, Amsterdam.

International Congress on Engineering Education

Prof. Richard Vieweg and Prof. Alwin Walther, with a small group of staff of the Darmstadt Technische Hochschule, are now trying to rebuild the college both as regards its buildings and its standing. They are accordingly organising, with the approval of the American Military Government, an International Congress on Engineering Education, to be held at Darmstadt during July 31–August 9. Feeding and housing of conference members from outside Germany will be undertaken by the American quartermaster's school at Darmstadt; suitable provision will also be made for Allied visitors from the other occupation zones. Darmstadt Technische Hochschule and the city of Darmstadt will furnish accommodation for Germans who attend. The preliminary programme indicates the following topics for discussion: (1) technology as an ethical and cultural opportunity; (2) present state and trends of development in engineering education throughout the world; (3) admission of students in relation to social problems; (4) exchange of professional ideas. Further information can be obtained from the Rector, Technische Hochschule Darmstadt, Kongressleitung, Darmstadt, U.S. Zone, Germany.

Announcements

Sir Robert Robinson, Waynflete professor of chemistry in the University of Oxford and president of the Royal Society, has been awarded the Albert Medal of the Royal Society of Arts "for his outstanding contributions to the advancement of organic chemistry".

Under the Statute of the Royal Society which provides for the election of persons who either have rendered conspicuous service to the cause of science or are such that their election would be of signal benefit to the Society, Mr. Clement R. Attlee has been elected a fellow of the Society.

Dr. John B. M. Coppock, head of the Technical Development Laboratories of the Fine Chemical Department, Boots Pure Drug Co., Ltd., Nottingham, has been appointed director of research of the recently formed British Baking Industries' Research Association.

Dr. F. N. Woodward has been lent to the Department of Scientific and Industrial Research for appointment as director of the United Kingdom Scientific Mission in the British Commonwealth Scientific Office in Washington. The present director, Dr. Alexander King, is shortly returning to the United Kingdom to take up an official appointment. Dr. Woodward is at present director of the Scottish Seaweed Research Association; during the War he was on the scientific staffs of the Ministries of Supply and Production. Dr. Woodward will also act as attaché for scientific questions to the British Embassy in Washington.

The Council of the University of Sheffield has made the following appointments: G. L. Hermitte, to be lecturer in histology; F. T. Thorpe, to be lecturer in mental diseases; R. M. Haythornthwaite, to be lecturer in civil engineering.

Mr. J. G. Pearce, director of the British Cast Iron Research Association, writes to point out that in the article in *Nature* of May 10, p. 649, on the Birmingham conference of the Federation of British Industries, the last sentence of the remarks attributed to him may give rise to misunderstanding. The full text was: "Of the major functions of a research association, the creation of new knowledge by research, its application in a given case through development, and its dissemination by intelligence activities, the problems of development and dissemination have been least satisfactorily solved . . ."

Erratum. In the communication "Nucleotide Metabolism of Bacteria and the Bacterial Nucleus" in *Nature* of April 26, p. 577, the illustration was inadvertently printed upside down.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications

Atomic Mass of Silicon

As is well known, the atomic mass of silicon has not yet been determined with satisfactory accuracy. The value given in the International Table of Atomic Weights is 28·06. Practically the same value, 28·063, was given by Baxter, Weatherill and Scripture[1] in 1923 from the ratio $SiCl_4/4Ag$. But from the same ratio, figures of $28{\cdot}11_1$ had been obtained in 1920 by Baxter, Weatherill and Holmes[2] and of $28{\cdot}10_5$ by Hönigschmidt and Steinheil[3]. Finally, in 1923, Weatherill and Brundage[4], from the ratio $SiCl_4/SiO_2$, gave the value $28{\cdot}10_6$. The three of the four modern gravimetric values are in fair agreement and lead to a mean figure of $28{\cdot}10_6$, which exceeds by 1/610 approximately the figure given in the International Table. This difference, considering the precision of modern gravimetric methods, is too great to be accepted without reservations, and it makes desirable and urgent a further revision of the atomic mass of silicon.

For this reason the recent publication of the experiments carried out by E. P. Ney and McQueen[5] with the mass-spectrograph on the isotopes of silicon must be welcomed. Subjecting silicon fluoride to an electronic bombardment, several ions are produced, among which the group SiF_3^+ is particularly interesting, from which it was possible to measure the mass and the abundance of the three isotopes, ^{28}Si (92·24 ± 0·10); ^{29}Si (4·69 ± 0·05) and ^{30}Si (3·07 ± 0·05). From these data, Ney and McQueen give the value of the atomic mass of silicon as 28·087, exceeding by 1/1039 the figure accepted by the International Commission.

The revision of the atomic mass of silicon has been undertaken at the Laboratory of Physical Chemistry of Compostela (Spain) using the pykno-X-ray method. This method, applied for the first time by Hutchison and Johnston to the determination of the atomic mass of fluorine[6], is based on the comparison of the molecular mass of the substance with that of calcite. The molecular mass of a crystal depends on: (*a*) the volume of its unit cell; (*b*) the number of molecules contained in the latter; (*c*) its density (ρ); and (*d*) Avogadro's number (N_A); hence when these values are known—at a given temperature—for the substance and the calcite, a simple formula enables the atomic mass to be calculated.

The compound chosen for the revision of the atomic mass of silicon was silica (SiO_2), in the form of α-quartz of hexagonal structure, the X-ray constants of which accurately determined by A. H. Jay[7] at 18° C. are: $a = 4{\cdot}9029$ A., and $c = 5{\cdot}3933$ A. As regards density, the pykno-metric measurements at 0° C., carried out by C. Gutierrez Losa in this Laboratory using our precision technique[8] with very pure transparent quartz from Noya (Corunna, Spain) give the mean value: $\rho_4^0 = (2{\cdot}6506_8 \pm 0{\cdot}0002_3)$ gm./cm.^{3}. Taking as coefficient of cubic expansion of α-quartz[9] the value $3{\cdot}529 \times 10^{-5}$, the density of SiO_2 at 18° C. will be: $\rho_4^{18} = (2{\cdot}6490_0 \pm 0{\cdot}0002_3)$ gm./cm.^{3}. As regards calcite, I have taken as molecular mass, $M_{CaCO_3} = 100{\cdot}090$, and as density, grating space and geometric structural constant, $\varphi(\beta)$, at 18° C., the values given by Bearden and Bearden and Shaw[10]: $\rho_4^{18} = 2{\cdot}71036$ gm./cm.^{3}, $d^{18} = 3{\cdot}02945$ A., and $\varphi(\beta) = 1{\cdot}09598$.

From the equations,

$$M_{SiO_2} = \frac{\sqrt{3}}{6} \cdot N_A \cdot \rho_{SiO_2} \cdot a^2 \cdot c$$

and

$$M_{CaCO_3} = 2 \cdot N_A \cdot \rho_{CaCO_3} \cdot \varphi(\beta) \cdot d^3{}_{CaCO_3},$$

and expressing the molecular mass of SiO_2 and $CaCO_3$ as a function of the other magnitudes mentioned, we conclude

$$M_{SiO_2} = M_{CaCO_3} \cdot \frac{\sqrt{3}}{12} \cdot \frac{\rho_{SiO_2}}{\rho_{CaCO_3} \cdot \varphi(\beta)} \cdot \frac{a^2 \cdot c}{d^3{}_{CaCO_3}}.$$

Substituting in this equation the various numerical values, we find $M_{SiO_2} = 60{\cdot}075$, the atomic mass of silicon being, therefore,

$$Si = 28{\cdot}075.$$

This determination is based on the molecular mass of calcite. This may not be the best reference substance for our purpose, since "it is well known to crystallographers that calcite always contains impurities"[11], and also because in the value of its molecular mass there is an approximate error of ± 0·007. On this account it is advisable, in my opinion, to take as reference substance sodium chloride, the molecular mass, density and grating space of which have been accurately determined. From

$$M_{NaCl} = 2N_A \cdot \rho_{NaCl} \cdot d^3{}_{NaCl}$$

it can be deduced that

$$M_{SiO_2} = M_{NaCl} \cdot \frac{\sqrt{3}}{12} \cdot \frac{\rho_{SiO_2}}{\rho_{NaCl}} \cdot \frac{a^2 \cdot c}{d^3{}_{NaCl}}.$$

Taking as molecular mass, $M_{NaCl} = 58{\cdot}454$, as density, at 18° C., the figure given by Johnston and Hutchison[12], $\rho_4^{18} = 2{\cdot}16396$ gm./cm.^{3}, and as grating space, $d^{18} = 2{\cdot}81425$ A., and substituting these figures in the above equation, we obtain $M_{SiO_2} = 60{\cdot}076$, or $Si = 28{\cdot}076$, in good agreement with the figure obtained taking calcite as reference. The mean value of the two atomic masses thus found,

$$Si = 28{\cdot}075,$$

is somewhat lower than the value found by Ney and McQueen, but higher than the one accepted by the International Commission. The most recent determinations seem, therefore, to suggest that the atomic mass of silicon is slightly higher than the one still given in the International Table.

Fluorescence of Solid Anthracene

The fluorescence of solid anthracene in light of wave-length 3650 A. is changed from blue to green when very small quantities of naphthacene are present in solid solution. This is explicable by an 'exciton' mechanism whereby energy is handed on by resonance from molecule to molecule[1]. The graphs shown here represent a quantitative examination of the effect, the blue and green components of the fluorescence being measured by a photo-cell through Ilford filters 601 and 404 respectively. The upper graph shows for two temperatures the fall of the blue anthracene fluorescence and the rise of the green naphthacene fluorescence with concentration of the latter, expressed as quantum efficiencies with a probable error of 15 per cent. The emissions are about equal at a naphthacene concentration of 3 × 10^{-5}, and the green reaches a maximum at about 10^{-3}. Above this concentration the colour of the emission changes to yellow as for pure naphthacene, and the efficiency decreases, evidently due to the overstepping of the limits of solid solution.

The supposed 'exciton' effect cannot be due to direct light absorption by the naphthacene owing to its feeble absorption at 3650 A. To eliminate the possibility that re-absorption of blue anthracene fluorescence followed by re-emission as naphthacene fluorescence is the cause, solutions of anthracene and naphthacene in acetone were poured into aqueous gelatine solutions to produce milk-like sols, the fluorescence of which could be measured under conditions of feeble light absorption. The lower graph shows as dotted curves the blue and green intensities for anthracene – naphthacene sols precipitated from one solution. These do not differ greatly from the curves of the upper graph for solid solutions made by fusion. The full lines, however, relate to anthracene – naphthacene concentrations made by mixing separately prepared sols of pure anthracene and of anthracene – naphthacene mixtures of concentration 10^{-3}. The differences for homogeneous and non-homogeneous mixtures of similar composition are strong evidence in favour of the 'exciton' hypothesis.

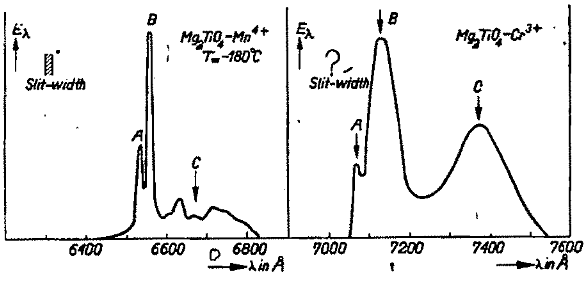
Tetravalent Manganese as an Activator in Luminescence

The fluorescence of luminophors activated with manganese, and also of pure manganese compounds, is generally attributed to divalent manganese[1]. The spectra emitted vary between green and red, and the width of the bands also varies from case to case, both probably being dependent on the magnitude and the symmetry of the electric lattice field at the position in the lattice at which the manganese ion is placed.

There is no doubt that this explanation is correct for the greater part of the manganese fluorescence known, and the colour differences between the green and red fluorescence respectively of zinc and magnesium silicates activated with manganese are certainly not due to differences in the valency of the manganese.

We have found some systems, however, in which also manganese of a higher valency can cause fluorescence. The emission due to these ions is situated in the red and shows a fine structure which is unusually sharp for manganese phosphors. In these systems, namely, zinc aluminate, magnesium aluminate, α- and β-aluminium oxide and magnesium titanate, all activated with manganese, the luminescence is markedly different according as the products are prepared under oxidizing or reducing conditions. The reduced products (except the titanate) show a green cathodo-luminescence. This emission is due to divalent manganese. The oxidized products show a deep red luminescence upon excitation by cathode rays or long-wave ultra-violet (3650 A.)[2]. This red fluorescence is due to manganese of a higher valency. In magnesium titanate the valency could be determined by chemical methods (titration), and was found to be between 3 and 4. That it is tetravalent manganese which is responsible for the red emission can further be proved by comparing the spectral distribution of the fluorescence of the salt when activated with manganese and with trivalent chromium respectively[3].



FLUORESCENCE SPECTRA OF Mg_2TiO_4—Cr^{3+} ACCORDING TO DEUTSCHBEIN (*loc. cit.*) AND Mg_2TiO_4—Mn^{4+}

The fluorescence spectra of these two substances (see graph) show a resemblance such as is to be expected for emissions which are characteristic of the iso-electronic ions Cr^{3+} and Mn^{4+} (both having a d^3 configuration) in the same surroundings[4].

Detailed results with these systems, including absorption, emission and excitation spectra, and the chemical methods used to obtain products with a maximum fraction of tetravalent manganese, will be published elsewhere[5].

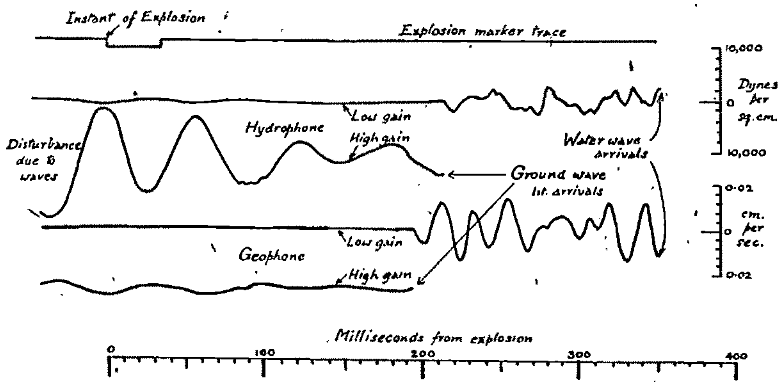
Marine Seismic Prospecting

In the years immediately preceding the War, considerable progress was made in the use at sea of the seismic method of studying submarine geology, and work was carried as far as the 100-fathom line. Further progress to deeper water was rendered difficult by the troubles arising in putting the instruments and explosives on the bottom of the sea. As a result of work in 1938 and 1939, it was suggested[1] that it might be possible to avoid these difficulties by having the instruments hanging in the water and relying on the transmission of the seismic waves from the bottom into the water. Unpublished observations during the War, both in Great Britain and in the United States, showed that seismic waves could, in fact, be observed in this way. In order to test the possibilities of the method, a direct comparison has been made of the signal received by a geophone on the bottom and by a hydrophone in the water. The explosive was also hanging in the water.

A calibrated moving-coil geophone, damped to give a constant velocity response from 30 to at least 100 c./s., was laid on the bottom with its axis approximately vertical. Its output was compared with that of a calibrated quartz-crystal hydrophone sensitive only to pressure changes, which was suspended about 40 ft. below the ship, and which had a flat response from 5 c./s. upwards.



RECORD SHOWING A COMPARISON BETWEEN THE SIGNALS PRODUCED BY A GEOPHONE AND A HYDROPHONE FROM THE SEISMIC WAVES RESULTING FROM AN UNDERWATER EXPLOSION

The output of each instrument was recorded at two levels of sensitivity, using four of the six strings of an Einthoven galvanometer. A fifth string was used to record the instant of explosion, so that the distance of the shot point could be determined from the transmission time of the direct wave through the water. Charges of 1–2 lb. of 'Polar Geobel', fired 100 ft. below the surface, gave satisfactory records up to 800 yards. A tracing from one of the records is shown in the figure. In this record the overall gain was adjusted so that the background-levels were visible on both high-gain strings, while the low-gain channels had about 24 db. less sensitivity. Under these conditions, the first arrival of the ground-wave was of sufficient amplitude to throw the high-gain strings off scale, while the direct water-wave produced a similar break in the low-gain traces. There was a considerable swell running when this record was taken, and the wind velocity was about 25 knots.

The charges used in the earlier experiments were attached to a buoy, fired by clockwork, and the instant of detonation transmitted to the ship by radio. This method was rendered cumbersome by the impossibility of controlling the instant of detonation after the buoy had been launched, and by the need for somewhat elaborate safety precautions. In most cases, therefore, the charge was trailed on an electric cable with floats every 100 yards. This method, while convenient at short ranges, could not easily be extended to distances greater than a few miles because of the labour of recovering the cable. For long-range work, it would be preferable to use a separate ship to fire the charge, as in the pre-war work, or to attach the hydrophone to a radio buoy which would transmit the signal back to the firing ship.

Difficulty arose from the transmission of mechanical disturbances down the instrument cables, but for the hydrophone this was overcome by giving the instrument a slight positive buoyancy, and by attaching a sinker about 30 ft. from the end of the cable. The geophone cable was similarly weighted, and the ship was allowed to drift freely during the recording period. Just before the shot, the geophone and weight were lowered to the bottom, and cable was paid out to allow for the movement of the ship. Under these conditions, the arrivals of the ground-wave were well defined, and the ratio of pressure to velocity agreed to within a factor of 2 with the theoretical value for plane waves in an infinite medium. Closer agreement was not to be expected, as the result was affected by reflexions from the surface, and by deviations of the geophone axis from the wave normal.

There seems no reason why this method should not be used in the deep ocean, and it appears to possess great practical advantages over any other that has been suggested.

The assistance of the Director of the Marine Biological Association at Plymouth for the laboratory and shipping facilities, and of the

Superintendent of the Admiralty Mining Establishment for the loan of the hydrophones and other apparatus, is gratefully acknowledged.

A New Method for the Observation of Zones of Colourless Substances on a Chromatographic Column

When chromatographic adsorption analysis is used for colourless substances (or on strongly coloured adsorbents, for example, activated carbon) it is impossible to see the zones of the different solutes adsorbed on the column. Some special arrangement is then needed in order to be able to locate the zones. In principle, two methods are available: (1) no observation is made on the column, but instead the concentration of the solution leaving the column is followed in a small cell; (2) the positions of the zones on the column are determined by using some special physical or chemical properties of the solutes. The first method, which was introduced by Tiselius[1] and improved by Tiselius and me[2,3], has also the advantage that the separation between two adjacent zones is greater in the filtrate than on the column. However, in many cases it is of importance to follow the separation directly on the column, and a number of different arrangements have been proposed[4]. In most of these cases the solutes either are converted into coloured compounds by means of suitable reagents, or indicators are applied before or after the chromatogram is finished, or use is made of fluorescence methods. These methods are, however, limited in use and unsuitable when zones are in direct contact with each other.

The new procedure to be described can be applied quite generally. The zones are detected on the column by observing the changes in refractive index of the solution in contact with the particles of the adsorbent. It is quite clear that this can be followed by any method for the determination of refractive index which uses the total reflexion of light entering through the glass wall of the tube in which the adsorbent is packed.

One of the simplest arrangements for the observation is the following. A tube with rectangular cross-section is used for the adsorbent (Fig. 1). Such a tube can easily be made by clamping two glass windows against a U-shaped plate of metal. One of the windows is rather thick and has polished edges. If the adsorbent is observed at the proper angle (Fig. 1) from a suitable distance (*c.* 1 metre), the boundary of the region of total reflexion is easily seen, and its position depends on the refractive index of the solution wetting the glass. Its shape will, therefore, be as in Fig. 2*a* in the case of an ordinary chromatogram with separate zones, and as in Fig. 2*b* if frontal analysis or displacement development is used. With strongly coloured adsorbents it may sometimes be useful to place a strip of thin white paper between the adsorbent and the glass window.

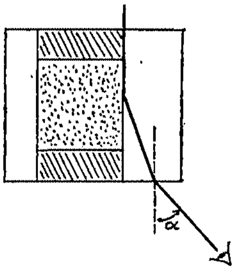

Fig. 1

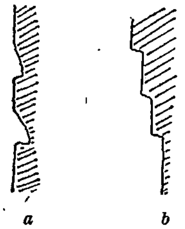

Fig. 2

Fig. 1. TUBE FOR CHROMATOGRAPHY SEEN FROM ABOVE
Fig. 2. SHAPE OF TOTAL REFLECTING REGION FOR (*a*) ELUTION ANALYSIS, (*b*) FRONTAL ANALYSIS

The operation of this method is in principle equivalent to that of a Pulfrich refractometer. It is clear that the sensitivity is improved by using monochromatic light during the observation. If necessary, the method can also be made quantitative by measuring the angle α with a telescope, since

$$n_0^2 - n_1^2 = \sin^2\alpha,$$

where n_0 is the refractive index of the glass and n_1 that of the solution. The accuracy can, of course, also be increased by using more elaborate methods for the observation; for example, an arrangement equivalent to a Hallwach's cuvette[5].

This method has the advantages that it can be applied quite generally and is independent of the specific properties of the solutes. Furthermore, it can be used when zones containing very similar substances with increasing concentration are in contact with each other, as in frontal analysis and displacement development. It seems also to be quite useful for inorganic chromatography. In the case of very large columns it is only necessary to place a strip of plane parallel glass in the wall of the container. It is also worth while to point out that different areas with different refractive indices can be detected in the same way when paper chromatography[6,7] is used, by placing the paper under the glass.

Although the method has the disadvantage that it is not so sensitive as most of the colour reactions, it does not exclude other kinds of observation, since the column can be observed in the usual way through the windows. Some experimental applications of the above principle will be reported later.

Set Time and Particle Size

In dissolving high-molecular weight compounds in hydrocarbons to give viscous solutions, it is convenient to stir or otherwise agitate the mixture until the viscosity of the solvent is raised to such a degree as to prevent any settling of the partially dissolved particles on standing. After such a 'set time' is reached, the material can be left to dissolve on its own accord. Homogeneity may be attained by a final shaking or mixing.

Set time as described above is a complex phenomenon governed by several factors. However, it is possible to correlate set time and particle size by a simple functional equation on the assumption that the method of attaining solution is standardized.

For any particle, the representative dimension of which is L, the viscosity, μ, is given by

$$\mu \propto L^2,$$

where μ is the viscosity of the solution required to give a standard rate of settling of the swollen particle the original dimension of which was L. This expression still holds for set time, T, defined as the time when the rate of fall of the swollen particle reaches a low standard value, which is undetectable over a period of one minute by the naked eye.

The viscosity of the colloidal solution can be given by the approximate proportionality, connecting μ and C, the concentration :

$$\mu \propto C^n,$$

where n is a variable index approaching 1 at zero concentration and has been found to be as high as 8 at high concentrations of macromolecules in hydrocarbons. Thus :

$$C \propto \sqrt[n]{L^2}.$$

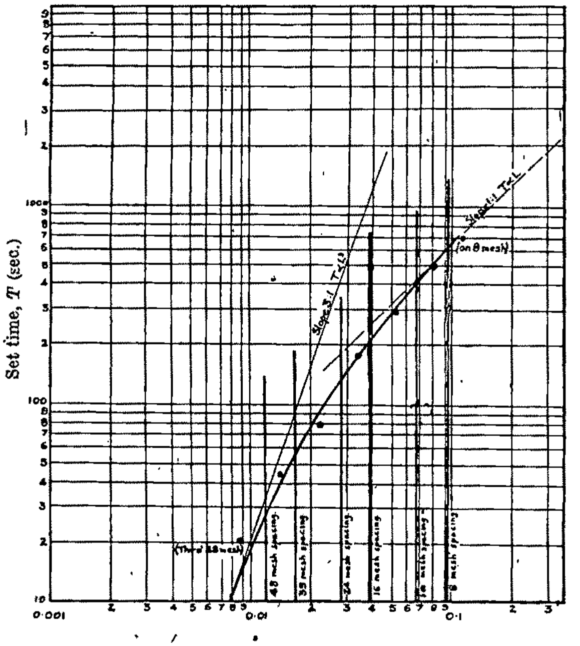
If the rate of solution, R, is approximately constant, due to stirring under standard conditions, then it is reasonable to put R as proportional to the specific surface of the particle per unit volume, that is,

$$R \propto 1/L.$$

Thus set time T will be reached when solution at the rate R yields a concentration C :

$$T = C/R \propto CL \propto L^{(1+2/n)}.$$

Thus for low concentrations ($n = 1$), T will be proportional to the cube of the representative dimension of the particle ; for high concentrations T is approaching a linear proportionality with L. As small particles require low values of C and large particles require high values, in order to be settling at undetectable rates, it follows that a plot of log T *vs.* log L should give a curve with log T varying with log L, so that $d(\log T)/d(\log L)$ is 3 at low values of L and unity at high values of L.



The accompanying graph gives the curve obtained for a series of sizes of a soap of aluminium. The agreement shown appears to justify the several assumptions made.

Absorption of Hydrogen by Aluminium Attacked in Caustic Soda Solution

In some experiments reported recently by Moreau and Chaudron[1], it was found that prolonged immersion of high-purity aluminium in dilute ($N/100$) caustic soda solution resulted in the absorption of large quantities of hydrogen by the metal, and that the presence of this gas had a measurable effect upon the elastic modulus. After 20–30 days immersion, the hydrogen content, measured by an ion-bombardment extraction method, was found to be as high as 1,000 c.c. per 100 gm. of metal. This measurement was carried out on specimens turned down from the original corroded blocks, and the results would, therefore, indicate that the absorbed hydrogen had penetrated to a considerable depth in the metal.

Such behaviour on the part of aluminium would imply that it can exhibit a condition analogous to that of steel which has been embrittled by pickling in certain circumstances ; this, as is well known, is associated with the absorption of large quantities of hydrogen, which apparently segregates along cleavage planes and lattice imperfections, and has a very deleterious effect on mechanical properties. No phenomenon of this nature has been found in aluminium or its alloys ; but an appreciable uptake of hydrogen by a similar mechanism might have less obvious effects, and play an important part, for example, in corrosion, particularly under stress. The latter possibility has been suggested by Goldowski[2].

Since the experimental results quoted above are at variance with our own experience, we have carried out some tests in which the corrosive conditions were, so far as we can judge, identical with those described by Moreau and Chaudron ; but the hydrogen absorbed by the specimens was determined by a hot-extraction method[3]. In these tests, two specimens of cast 99·99 per cent aluminium, each weighing about 10 gm., were immersed in ($N/100$) caustic soda for 49 days, the solution being renewed at frequent intervals when the reaction appeared to be slowing down. The specimens each lost about half a gram in weight and were very deeply etched, especially at the grain boundaries. On removal from the solution they were washed in 1 per cent acetic acid and dried without handling. One specimen was degassed without any further treatment, and evolved hydrogen equivalent to 0·47 c.c./100 gm. of metal, and a much smaller volume of other gases, mainly carbon dioxide. The second specimen was skimmed to a depth of about 1 mm. on a lathe before degassing, and in this case the hydrogen content was found to be 0·43 c.c./100 gm., with a lesser volume of other gases than in the first experiment.

Other experiments indicate that with the latter treatment the bulk of the gases other than hydrogen, and about 0·05 c.c./100 gm. of the hydrogen itself, is associated with the oxide film which is inevitably present on the metal. The correction to obtain the true value of dissolved hydrogen is probably greater than this for the unturned specimen. We thus find that the hydrogen content of the corroded metal is rather less than 0·4 c.c./100 gm., with no evidence of a high concentration in the surface layers. A gas content of this order is quite normal for cast aluminium, and we therefore conclude that no appreciable absorption of hydrogen takes place under our conditions. We have certainly been unable to detect any effect of the magnitude described by Moreau and Chaudron.

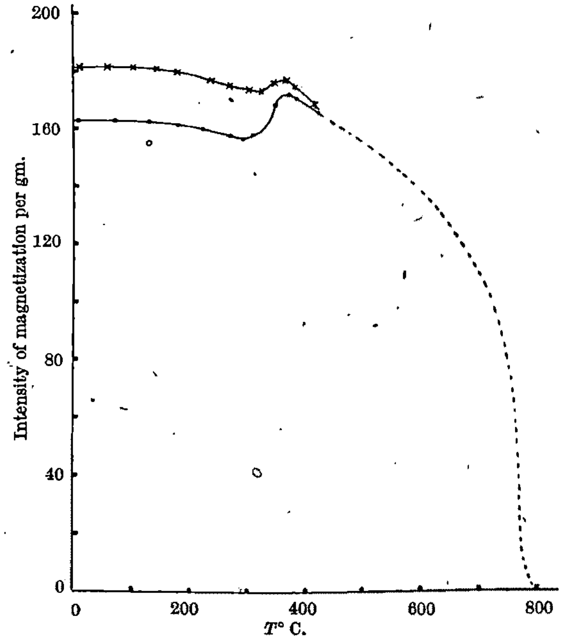
'Spoiling' of Tungsten Steel

It is known that the coercive force of tungsten magnet steel is reduced if the steel is maintained for a period at a temperature of 950–1,000° C. prior to hardening. The steel is then said to be 'spoiled'. In some such samples of tungsten steel the compound WC has been detected, and it has been suggested that the tungsten and carbon remaining in solution are insufficient to promote good hardening[1,2]. Experiments have been made on an unspoiled steel with the following analysis: W, 5·65; C, 0·72; Cr, 0·27; Si, 0·24; Mn, 0·3 per cent.



●—●, quenched from 850° C.
×——×, annealed at 950° C. for 64 hr. and quenched from 850° C.

Small samples of this steel were heated for various times in an enclosed quartz tube at 950° C. Later, while still in the tube, they were quenched from 850° C. in water. The intensities of magnetization of these samples were measured by means of a Sucksmith balance[3] at various temperatures. The field of 11,300 Oersted was sufficient to produce saturation. The figure shows curves of specific magnetization against temperature for two specimens treated in this way, the periods for which the specimens were kept at 950° C. being zero and 64 hours respectively. The specific magnetization of these specimens at room temperature after annealing in a region between 400° C. and 700° C. is always about 189.

The curves can be explained by assuming that the quenched specimens contain some austenite which is non-magnetic. On heating to 300° C., the austenite is transformed into a magnetic martensite or ferrite. (The change actually occurs slowly between 250° and 300° C., but the curves shown were taken with the temperature rising fairly rapidly, and consequently the transition appears at a slightly higher temperature.) The percentage of austenite can be estimated either (*a*) by assuming that it is proportional to the amount by which the specific magnetization at room temperature is less than that for a completely ferritic specimen, or (*b*) from the increase in the specific magnetization at 300° C. shown in the figure. Results using the two methods of estimation are shown in the table.

	Time at 950° C. (hr.)	σ	% of austenite	
			Method *a*	Method *b*
1	0	161·2	15	12
2	0	162·9	14	12
3	1	170·0	10·5	10
4	4	173·5	7	7
5	64	178·5	5	5

The percentage of retained austenite can be seen to decrease progressively as the time of annealing at 950° C. increases. To explain this result it may be assumed that at 950° C. tungsten and carbon combine to form a separate carbide phase, the reaction proceeding rather slowly and approaching equilibrium exponentially according to the law of mass action. The remaining solid solution becomes less rich in these elements, and since it is the presence of tungsten and carbon that enables austenite to be retained on quenching, the percentage of austenite retained will decrease as the amount of tungsten carbide increases.

The specimens were also examined microscopically, but it was not found possible to estimate the quantity of austenite by this method; but an increase in the patterns usually attributed to WC was observed as the time of annealing at 950° C. increased.

These experiments strengthen the theory that the 'spoiling' of tungsten magnet steel is caused by the formation of a separate carbide phase which reduces the amount of tungsten and carbon available to promote hardening.

We wish to acknowledge our thanks to the Permanent Magnet Association for permission to publish this note.

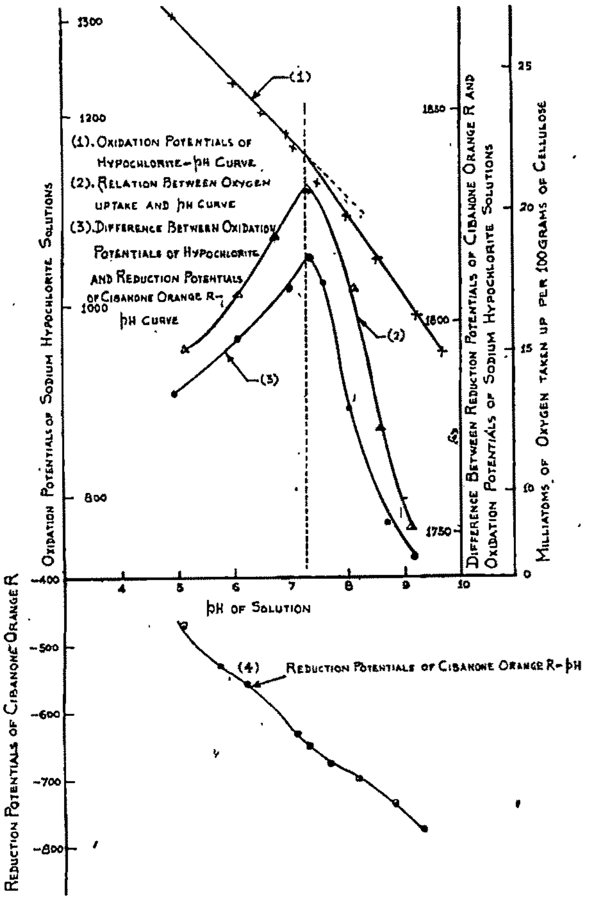
Accelerated Oxidation of Cotton Cellulose in Presence of Reduced Cibanone Orange R

THE rate of oxidation of cellulose by dilute solutions of sodium hypochlorite has been shown to be accelerated if certain vat dyes are also present in the reduced form upon the fibre[1,2]. Ferrous hydroxide precipitated on cellulose exerts a similar influence on the rate of oxidation[3]. The mechanism of this acceleration is not yet clear. It has been suggested[2] that the difference between the oxidation potential of the oxidizing agent and the reduction potential of the vat dye may be the determining factor in the acceleration of the oxidation. The present investigation deals with the measurement of reduction potentials of vat dyes upon the fibre and their influence on the acceleration of the rate of oxidation of the cellulose substrate by dilute sodium hypochlorite solutions.



Loose cotton dyed with Cibanone Orange R was tightly wrapped round a stout platinum wire. The dyestuff on the cotton was chemically reduced, and the free leuco compound was prepared by washing away the soluble impurities with oxygen-free distilled water. The electrode was then immersed in an oxygen-free buffer solution of known hydrogen ion concentration through which hydrogen gas was bubbled vigorously for fifteen minutes. The E.M.F. of the following cell was measured at short intervals:

+ Hg | Hg_2Cl_2,Sat.KCl || Sat.KCl || Leuco Cibanone Orange R dyed cotton in buffer solution | Pt −

The E.M.F. reached a constant value after about fifteen to twenty minutes and remained steady for periods varying between half to one hour. This constant value was taken as the E.M.F. of the cell. The potential of the half-cell

Pt | leuco Cibanone Orange R (dyed cotton in a buffer solution)

was calculated from the E.M.F. of the above cell. This value has been referred to as the reduction potential of Cibanone Orange R. The oxidation potentials of sodium hypochlorite solutions and the oxygen uptake by reduced Cibanone Orange R dyed cotton were measured by the method described by Nabar, Scholefield and Turner[3]. All measurements have been carried out at 30° C. The results are illustrated in the accompanying graphs.

It will be noted that the curve relating *p*H to oxygen uptake closely resembles the curve showing the relation between the *p*H and the difference between the oxidation potentials of hypochlorite solutions and the reduction potentials of Cibanone Orange R. A few other dyes examined show similar behaviour.

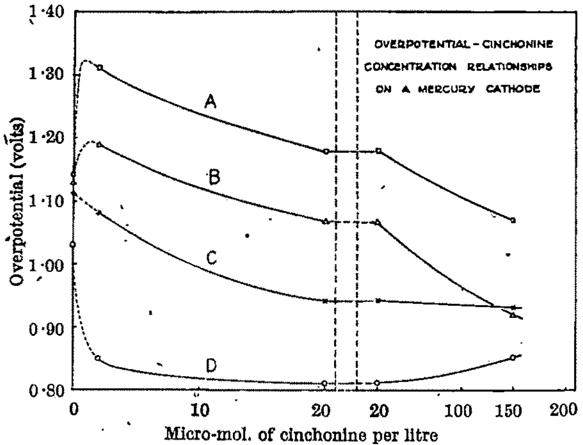
Effect of Alkaloids on Hydrogen Overpotential

IT is well known that certain substances, such as arsenious oxide[1], when added to a solution in which is a working electrode evolving hydrogen, considerably increase the hydrogen overpotential at the cathode. Such substances are often referred to as 'poisons'[2], and a detailed knowledge of their effects on irreversible electrode potentials appears to be of considerable importance in the elucidation of the mechanism of overpotential. It seemed probable that some additives might exist which function as 'activators' and thus decrease hydrogen overpotential at various current densities. Such substances have been found among certain alkaloids of the quinoline group.

Hydrogen overpotential has been measured by the direct method at current densities from 10^{-3} to 10^{-1} amp./sq.cm. on cathodes of mercury, lead, tungsten and platinized platinum in pure aqueous solutions of hydrogen chloride and in solutions containing quinoline, cinchonine, quinine, narcotine and morphine in concentrations from 2 to 150 micro-mol./litre. Marked lowering effects are observed in solutions containing these quantities of the alkaloids named above, particularly at lower current densities on mercury cathodes. Smaller lowering effects occur for lead; tungsten cathodes are little affected, and on platinized platinum all the above-mentioned alkaloids act as poisons.



A, 10^{-1} amp./sq. cm.; *C*, 10^{-2} amp./sq. cm.
B, 5×10^{-2} „ „ ; *D*, 10^{-3} „ „ .

Detailed results for mercury cathodes are given in the accompanying table, and a typical dependence of overpotential on concentration of alkaloid present is shown in the graph for mercury cathodes in solutions containing cinchonine.

EFFECT (APPROXIMATE) OF ALKALOIDS ON OVERPOTENTIAL ON MERCURY

Alkaloid		At 10^{-3}–10^{-2} amp./sq. cm.	Volts	At 10^{-2}–10^{-1} amp./sq. cm.	Volts
Quinoline	Lower conc.:	lowered	0·1	raised	0·1
	Higher conc.:	lowered	0·2	raised	0·2
Cinchonine	Lower conc.:	lowered	0·2	raised	0·1–0·2
	Higher conc.:	lowered	0·2	lowered	0·15–0·2
Quinine	Lower conc.:	lowered	0·2	raised	0·25
	Higher conc.:	lowered	0·1–0·2	raised	0·1–0·2
Narcotine	Lower conc.:	lowered	0·05	raised	0·1–0·2
	Higher conc.:	raised	0·05	raised	0·2–0·3
Morphine	Lower conc.:	lowered	0·05	raised	0·2
	Higher conc.:	raised	0·1	raised	0·3

The most notable features of the present results are that the lowering effects of the alkaloids increase with concentration at a given current density, and that they depend markedly upon the nature of the cathode material. Presence of alkaloid generally decreases the *b* factor of the Tafel equation[3] at low current densities and increases it at high current densities.

The results on mercury may be compared with the observations of Pech[4] and of Herasymenko and Slendyk[5] on the effects of alkaloids on the polarographic half-wave potentials, which were found to be changed by the presence of certain of these substances to more positive values.

The above work forms part of a comprehensive study of the effect of poisons on hydrogen overpotential which is being carried out in this Department. A detailed discussion will be published elsewhere.

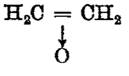
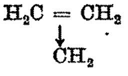
Structures of Ethylene Oxide and Cyclopropane

MY suggestion[1] that ethylene oxide and cyclopropane might be portrayed as (I)–(II) rather than (III)–(IV) has been criticized[2,3]. I wish, therefore, to discuss my suggestion, further.



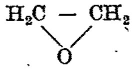
$$H_2C = CH_2 \atop {\downarrow \atop O}$$

(I)

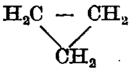


$$H_2C = CH_2 \atop {\downarrow \atop CH_2}$$

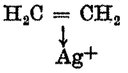
(II)



(III)

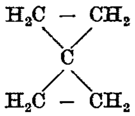


(IV)



$$H_2C = CH_2 \atop {\downarrow \atop Ag^+}$$

(V)



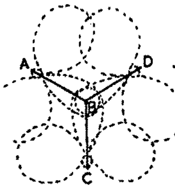
(VI)

My underlying ideas were: (1) evidence on olefinic donor properties suggests (I)–(II), just as (V) is known; (2) the carbon atoms involved are nearer the trigonal or ethylenic than tetrahedral state. Evidence for (2) seems very strong. (*a*) It is outstanding that epoxy or cyclopropyl groups joined to C=C show just those spectroscopic and chemical properties characterizing conjugation. Theory explains conjugation thus. All the carbon atoms involved are in the trigonal state: 2*p* atomic orbitals on neighbouring carbon atoms overlap to give a nonlocalized molecular orbital. The conjugation phenomena follow from the delocalization. Hence the idea that ethylene oxide and cyclopropane contain near-trigonal carbon atoms and molecular orbitals which, being built from 2*p* atomic orbitals, inevitably overlap with neighbouring 2*p* atomic orbitals. (*b*) The low dipole moment of cyclopropyl chloride: the high electronegativity of a trigonal carbon atom in its hybrid valencies[5], as in vinyl chloride, explains this. (*c*) The height of the strong CH Raman frequencies and the unsaturation properties of ethylene oxide and cyclopropane.

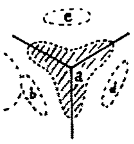
One is therefore led to structures with carbon atoms near the trigonal state. (I)–(II) suggest the existence of trigonal carbon atoms, non-localized orbitals, unsaturation, conjugating power. (III)–(IV) do not.

(I) suggests resemblance to amine oxides. Such is seen in work by Karrer[4], to which Sir Robert Robinson does not refer: certain epoxy groups *do* lose oxygen readily (→C=C). I do not suppose likeness between (I) and amine oxides to be *very* close: the orbital symmetries involved are so different. Similarly, analogy between (I) and (V) is not *very* close, for O, unlike Ag^+, has further valency orbitals which must be involved: their importance can be seen below.

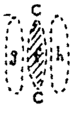
It is clear that the probable symmetry (from infrared data: *not* from intuition, which would suggest O_3 to be equilateral) of cyclopropane enforces superposition of three forms like (II). The resultant is not (IV), for it is still based on trigonal rather than tetrahedral carbon atoms. In the hybrid, the CH_2 planes must bisect the CCC angles: molecular orbitals are formed by overlap of (*a*) three hybrid sp^2 atomic orbitals, (*b*) 2*p* atomic orbitals. (VII) shows this: *AB*, *CB*, *DB* are CH_2 planes at 90° to the paper. The result has some of the character of (VIII). Two electrons occupy the three-pronged area *a*, two may be found either in *b* or *d* or *e*, and two lie in an orbital that represents a first overtone of *a*. The latter are 'anti-bonding' electrons: their presence reflects repulsion in (II) between the lone pair and other electrons. *b*, *d*, *e* are regions of high amplitude in an orbital with no actual nodes.



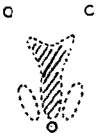
VII



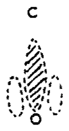
VIII



IX



X



XI

The resonance description of cyclopropane on my model is as a hybrid of three forms (II), the molecular orbital description partly as (VIII). The orbital pattern (VIII) to which we have been led is a generalization to three centres of the orbital picture (IX), which theory has evolved to explain two-centre unsaturation and make redundant the old distorted tetrahedral model for ethylene. *f* represents the σ, *g*–*h* the π orbital. (That (IX) and (VIII) *are* the same geometrical pattern applied to two and three centres respectively can be shown by folding filter papers along (i) two diameters at 90°, (ii) three at 60°, making the same cuts in each and opening out; *f* becomes *a*, *g*–*h* become *b*–*d*–*e*.) The molecular orbital picture for ethylene oxide is as (VIII), except that the dipole means *e* is now tenuous, *b*–*d* drawn downwards, the upper prongs contracted. (X) ensues. One reaches the same essential result[5] by considering the single structure (I) as the major resonance form. A >C=O group has the molecular orbital picture (XI). Some resemblance of ethylene oxide to CH_3CHO may therefore follow. Cationoid character comes from a large partial positive charge on the CC of (X), as on C of >C=O.

(VII) implies, besides (VIII), some localized-bond character. The overlap between any pair of $2p$ atomic orbitals is neither 'sideways' nor 'endwise'. So far as it is the latter, the resulting molecular orbital overlaps little with the third $2p$ atomic orbital, that is, localized bonds at *b*, *d*, *e* result, *a* is vacated and its component atomic orbitals, mixed with the original carbon atomic orbitals, cause some change towards tetrahedral atoms. The angle between the $2p$ axes is such that sideways overlap, with resulting non-localization, is greater than endwise—in accord with the carbon atoms being nearer trigonal than tetrahedral. In cyclobutane the angles are such that localization is greater and four-centre unsaturation less. Even in cyclohexane, however, a greater tendency (than in paraffins) towards $2p$ character in the C—C and of $2s$ in the C—H valencies is shown by CC weakness and CH strength[5].

In azoxy compounds, lone pairs and not bonding electrons are donated. This is not against (I), as ethylene has no lone pair. It is significant that azoxy groups do *not* form strained rings, though far less distortion of natural valency angles is necessary than in (I). A most important stable molecule to consider is spiropentane, usually drawn as (VI). My ideas are readily extended to this molecule, the central carbon atom being digonal and the two CCC planes at 90°.

Dr. McDowell's arguments seem not to affect my model. I do not expect (I)–(II) to show olefinic frequencies: the disturbance is too great for this. I *expect* S +—*R* to be able to replace NH or CH_2 or O.

So far as I can see, my model explains qualitatively all the salient facts. I think, therefore, (I)–(II) possible single formulæ, full descriptions (especially with (II)) needing hybridization with like forms; but if entirely new symbols for the binding at issue be suggested, I shall quite agree. I have been mainly concerned to apply wave mechanical principles to the problem—though Sir Robert Robinson apparently does not realize this. As regards co-ordination by bonding electrons, my contribution was to try to combine clear statement with a rational basis for assessing donation probability, namely, ionization potential knowledge.

Status of Potato Virus B

POTATO virus X is known to exist in many strains. Potato virus B has been considered to differ from all other strains of potato virus X, on account of its reactions on several potato varieties.

Clinch[1] considered 'Up-to-Date streak' to be synonymous with virus B of Bawden[2]. She was not certain whether a strain of X was present in her stock of Up-to-Date, along with the strain causing streak. However, it seems definite that Bawden's material contained a 'normal' X strain, as well as B in some plants at least.

Cockerham[3] described the reactions on several hosts, including a large number of potato varieties, of a virus from Duke of York potatoes. He considered this virus to be pure virus B. Bawden and Sheffield[4], working with this material, showed by cross-absorption tests that B and several strains of X were all serologically related but not identical. One of the X strains used (X^a) resembled B in some host reactions and not in others. They point out that a simple test based on host reactions is not a valid test of relationship.

'Up-to-Date streak' virus in Up-to-Date, supplied by Clinch, has been compared serologically with virus B from Bawden's source in Duke of York.

Rabbit antisera to the virus were prepared from the two sources. *Nicotiana glutinosa*, inoculated directly from potato, was used as the starting material for partially purified preparations of the virus free from tobacco mosaic. These preparations were used in absorption experiments. Cross-absorption tests, made with virus in slight excess, showed that both sources of the virus have an antigenic portion in common (7/8), and that each has a fraction distinct from the other (1/8 in each case), using the serum end-point as an estimate of the fractions.

It is concluded that virus B from Duke of York potato has an antigenic portion differing from the streak virus in Up-to-Date. The reverse is probably true. However, the possibility that part of, or all, this difference is caused by an X-type strain, present along with the streak strain in Clinch's material, has not been eliminated.

It is suggested that virus B is no more a single entity than is virus X. It is possible that many strains of virus X may be found which do not give top necrosis on varieties like Epicure and King Edward. This conclusion, together with the findings of Bawden and Sheffield[4], indicate that there is no sound basis for giving the strains known as 'virus B' any special status within the X group. There seems to be no good reason why the reactions on a few arbitrarily chosen varieties of potato (or any other single host) should have any special significance as a basis for the classification of X strains into groups.

The value of the cross-absorption figures as a quantitative estimate of the 'common' and 'non-common' portions on the particle is very doubtful. Nevertheless, carried out with a number of strains, it may give some indication of the relative extent of antigenic relationship.

My thanks are due to Dr. Phyllis Clinch and Mr. F. C. Bawden for supplies of their material, and to Dr. K. M. Smith and Dr. Roy Markham for helpful criticism.

A Protozoal Disease of South African Trawled Fish and its Routine Detection by Fluorescence

Recent investigations into the problems of (*a*) 'mealiness' of the cooked flesh of the Cape John Dory (*Zeus capensis*) and (*b*) milky spots in smoked fillets of the stockfish (*Merlucius capensis*) have revealed that the abnormalities are a consequence of heavy infections of the muscle fibre by a protozoal parasite. The parasite is identical to that described by Gilchrist[1] as *Chloromyxum thyrsites* causing the 'pap' condition of the snoek (*Thyrsites atun*). Fantham[2], however, suggested that the organism might be identical to *Chloromyxum quadratum*, Thélohans.

Gilchrist reported that 5 per cent of the snoek catch were so heavily infected as to be of no commercial value, and that microscopic examination of the flesh of twelve fish selected at random and considered perfectly healthy revealed that eight of the fish were infected.

In the John Dory, approximately 25 per cent of the catch landed are extremely emaciated, with the flesh so soft that it cannot be filleted. It is just possible to detect less severe infection at the time the fish is landed by trawlers, by the greater opacity of the infected muscle fibres, while 36–48 hours later the infection is clearly visible as milky areas embedded in the flesh.

In the stockfish there are no visible signs of infection until after the fillets have been smoked, when the infected areas appear as whitish spots embedded in the flesh. The 'milky' spots, on pressing, exude an ooze of disintegrated tissue heavily impregnated with the characteristic spores of the parasite.

The discovery that infected muscle fibres fluoresce under ultra-violet light filtered through Wood's glass has made it possible to survey in large samples of the catch, (*a*) the distribution of infection within the tissues, (*b*) the intensity of infection, and (*c*) the number of fish infected. The infection is limited to single or a few adjacent muscle fibres distributed at random throughout the flesh. Such muscle fibres fluoresce brilliantly in the stockfish, and even deeply embedded infections can be detected without difficulty. In the John Dory, the intensity of the fluorescence is not so great, but is ample to indicate even a single infected fibre in the whole fish. The fluorescence is greatly diminished in salted fish.

The extent of the infection in the trawled fish may be gauged from the following data.

Fish	No. examined	% Infected
John Dory	596	76
Stockfish	660	70

The extent of the infection may vary from a single muscle fibre to a state in the John Dory in which the fluorescing fibres permeate the whole flesh. It is difficult to imagine how such fish can move and live. It is probable that only the numerous spines with which the John Dory is protected save the heavily infected individuals from becoming easy prey to other fish. Heavy infection of the order encountered in the John Dory has not been seen in the stockfish; but there is no clear evidence to indicate whether this is due to greater resistance or to the elimination of the fish as soon as the infection reaches moderate proportions, when muscular movement might be affected.

The John Dory catch is also characterized by the preponderance of female to male in the ratio of approximately 2 : 1. The distribution of the intensities of infection in male and female fish and the proportion of infected individuals among the sexes seems to indicate that the male fish are more susceptible and that the disease progresses more rapidly in the male. There is strong presumptive evidence of considerable mortality in the John Dory from this disease. It is of considerable interest that Gilchrist suggested in 1924 that the occasional meagreness of the annual shoals of snoek visiting the Cape could probably be ascribed to this disease.

Details of this investigation will be published elsewhere.

Population Studies in Fisheries Biology

G. L. Kesteven has stressed[1] the need for a dynamic approach to the study of fish populations. It has been possible recently to develop a mathematical treatment having certain features in common with that of Baronov[2], which bears this necessity in mind, and which we feel will be of value in further consideration of fisheries problems, and in particular has immediate application in the assessment of remedies for overfishing.

Russell's equation[3] expresses the dependence of the yield from a fishery on the vital coefficients of the population (natural mortality, recruitment and growth) and the rate of fishing. In its original form, this equation is not an analytical tool, as Kesteven points out. It is possible, however, to express these fundamental relationships in a form that would enable application to any population of fish for which there are sufficient data.

We shall define the primary factors that enter into a determination of the rate of yield, in terms of the coefficients of recruitment (B), growth ($W(t)$) and natural and fishing mortalities (M, F), M including a factor for loss by emigration from the area considered. All other factors, such as population density and mesh selection in so far as they influence the rate of yield, do so by virtue of their effect on these primary coefficients, and thus can be incorporated into the equations.

If B is equal to the number of fish attaining fishable size per year, and the coefficients are effective over a period λ years, the fishable life-span of the species, it can be shown that:

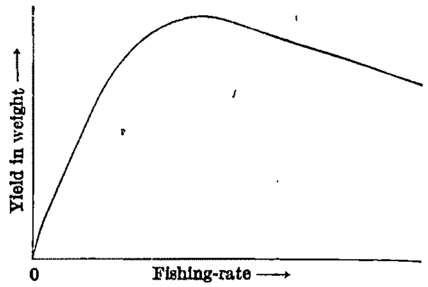
$$Y = \sum_{n=0}^{\lambda-1} \int_{t=n}^{n+1} W(t).F.B.\exp\left(-\int_0 F + M\right) dt,$$

where Y is the yield in weight per annum. It must be emphasized that this, and the following example, apply only to equilibrium condition.

To illustrate the form which the equation may take, we consider the simplest case, where B, M and F are constants, and $W(t) = \alpha + \beta t$.

$$\text{Then } Y = B.F. \int_0^{\lambda} (\alpha + \beta t) \exp(-(F + M)t)$$

$$= \frac{B.F}{F+M}\left[\alpha + \frac{\beta}{F+M} - \exp(-(F+M)\lambda \left(\alpha + \beta\lambda + \frac{\beta}{F+M}\right)\right]$$



There is a field in which this equation can be applied as a first approximation. A fuller treatment requires a determination both of the variable components affecting the primary coefficients and of the significance of possible departures from the steady state.

Further details of this procedure and its applications will appear elsewhere.

Influence of the Medium on the Inactivation of Tetanus Toxin by X-Ray Irradiation

THE inactivation of diphtheria toxin by ultra-violet light was first demonstrated by Hertel[1] in 1904. This observation was fully confirmed by other workers for different toxins. Attempts to destroy toxins by means of irradiation with X-rays or radium have hitherto been unsuccessful. Only Ferroux and Muttermilch[2], using exceptionally large doses of radium and highly diluted tetanus toxin, reported destruction of the toxin.

Using considerably greater doses of X-rays than previous authors, we were able to inactivate tetanus toxin and to study the influence of the medium on toxin inactivation *in vitro* by X-rays. The influence of the medium on the destruction by X-rays of viruses, enzymes and other experimental material has already been demonstrated.

Material and Methods. We have used two types of tetanus toxin, prepared in different ways:

(1) A tetanus toxin prepared by culturing tetanus bacilli anaerobically for 14 days in meat infusion broth containing glucose, and afterwards purifying the product by Eaton's method[3]. Such a toxin sample contained 1,000 minimum lethal doses (M.L.D.) in 1 c.c., and yielded 0·14 mgm. nitrogen per 1 ml. in a micro-Kjeldahl test. It will be referred to as $T1$.

(2) The second tetanus toxin sample employed was prepared by culturing tetanus bacilli in Mueller's medium[4] and diluting the product so that it contained 1,000 M.L.D. per 1 ml. This yielded 4·5 mgm. nitrogen per ml. in the micro-Kjeldahl test. It will be referred to as $T2$.

Irradiations were carried out with an Ott tube operated at a tension of 35 kV. and a current of 5 m.amp. with a copper anticathode. The distance between the vessel in which the toxin was irradiated and the focal point was 50 mm., and the intensity of the X-rays was about 90,000 r./min. The window was aluminium foil 30 μ in thickness.

Samples of toxin (0·1 ml.) were irradiated in vials with a diameter of 15 mm., the depth of the liquid in the vials being 0·6 mm. After irradiation the treated toxin solutions were serially diluted to varying extents with saline. At least four white mice, averaging 20 gm. in weight, were inoculated with each of the toxin solutions. Unirradiated control samples of toxin were similarly treated.

The medium was varied by adding a series of proteins and peptones to samples of $T1$.

Results. A dose of 7 million r. suffices totally to destroy the 100 M.L.D. contained in 0·1 ml. of the original standard $T1$ sample, whereas lower dosages only partially inactivated the original 100 M.L.D. The extent of toxin inactivation was determined by the inoculation of varying dilutions of the irradiated original standard toxin sample. In this way it was found that a standard $T1$ sample, after exposure to 4 million r., contained 50 per cent (50 M.L.D.) of the toxin originally present. Doses of 3 million r. inactivated 20 per cent (20 M.L.D.) of the same toxin, and 2 million r. only 5 per cent (5 M.L.D.).

X-ray irradiation of tetanus toxin $T2$ proved to have a less marked effect. Doses of 7 million r. inactivated only 20 per cent of this toxin (20 M.L.D.); 3–5 million r. destroyed approximately 10 per cent (10 M.L.D.). This difference in behaviour between $T1$ and $T2$ is probably associated with the greater purity of tetanus toxin No. 1. W. Dale[5], working with enzymes irradiated *in vitro*, reported the 'protective' action of certain substances contained in the medium. Similar observations on the protective action of certain substances against X-irradiation have been reported earlier[6–8] for viruses and enzymes.

In order to determine the possible association of different proteins and protein peptones with the enhanced resistance to X-rays, we added a series of these substances to samples of *T*1 before irradiation. The addition of different substances to the medium diminished the X-ray effect on the toxin in varying degrees.

In a number of experiments in which albumin was added, it could be observed that 10 per cent of albumin in the medium completely blocked the inactivating effect of 4 million r. on tetanus toxin (*T*1). Lower albumin content had a less noticeable protective action, and 0·1 per cent of albumin no longer had any demonstrable protective action against irradiation with 4 million r.

Protective action was noted after the addition of albumin, albumin peptone, rabbit serum, protamine, and globulin-peptone. No protective action was induced by the addition of globulin, casein, casein peptone, gelatine, edestin and irradiated toxin.

It is to be noted that substances, such as gelatine, which have a protective effect on certain other test objects such as sperm and hormones, exhibited no protective action on tetanus toxin in our experience.

This investigation has been carried out with the aid of a grant from the British Empire Cancer Campaign.

Value of Adding Cotton-Seed, Okra and Fenugreek to Maize Flour

THE association of maize-eating with pellagra and the prevalence of this disease in Egypt have, from time to time, suggested the replacement of maize by some other flour in bread-making; this being impracticable, attempts have been made to raise the nutritive value of maize by supplementing it with other flours. In Egypt, the problem has been unintentionally solved by peasants who have adopted the addition of either fenugreek (*Trigonella Fœnum-græcum* L.), or okra (*Hibiscus esculentus* L.) to maize flour. The resulting bread was very satisfactory, at least so far as added fenugreek is concerned, and it compared well with wheaten bread.

It occurred, however, to those interested in cotton-seed by-products to recover the proteins of the seed after the extraction of the oil and to use the resulting flour as a supplement to maize. The cotton-seed flour is a fine product with yellow-green colour and no particular odour or taste. Its reaction is acid, and it contains 8·75 per cent of moisture, 5·91 per cent of fat, 51·35 per cent of raw proteins, 4·11 per cent of raw fibres, 8·62 per cent of ash and 21·26 per cent of nitrogen-free soluble substances.

Supplementary value of the seed proteins. Unlike wheat, maize flour does not possess the sticky gluten which characterizes wheat. The Egyptian peasant's idea in adding fenugreek to maize flour probably aims at producing a more or less cohesive mass with the help of fenugreek mucilage. When fenugreek is scarce or when it is expensive, the peasants employ instead okra, which contains a similar mucilage. Both fenugreek and okra are local products and are very cheap in comparison with the cotton-seed flour.

It therefore appeared desirable to compare the nutritive value of maize to which cotton-seed flour is added with maize plus fenugreek or okra. Young growing rats were used as experimental animals. Fed as a supplement to a maize diet adequate in all respects except for its protein component, cotton-seed flour at a 4 per cent level enhanced growth in a similar way to that induced by fenugreek or okra supplement at the same level. The increments obtained were 13, 34, 25 and 32 gm. for the basal diet, the basal plus cotton-seed flour, plus fenugreek and plus okra respectively. It might be argued that cotton-seed flour is not bitter, and that unlike fenugreek more of it can be added to maize with impunity. Such addition may increase the nutritive value of the bread and be a point in favour of the cotton-seed flour. It will be remembered, however, that while the bitter taste of fenugreek restricts its use, there are no such restrictions in the case of okra. It was therefore decided to make a fresh comparison with higher supplements of these seeds. Diets of the same compositions but containing 10 per cent of the different supplements were employed, using again young growing rats. When the level was raised to 10 per cent, it was found that the biggest increment was obtained in the case of the okra supplement (77 gm.), then came fenugreek (72 gm.), and finally the cotton-seed flour (48 gm.). If the different supplements were compared by dividing the weight increase by the protein content of the supplement in the different diets (proteins of cotton-seed flour, 51 per cent; fenugreek, 23 per cent; and okra, 18 per cent), then at both the 4 per cent and the 10 per cent levels the protein value of fenugreek is 2·5 times that of cotton-seed flour, while okra is 1·5 times that of fenugreek.

Vitamin content of cotton-seed flour. Biological experiments were made to test for the presence of vitamin B_1 and nicotinic acid, while vitamin A and its precursor carotene were determined spectrophotometrically. Cotton-seed flour contains an amount of vitamin B_1 equivalent to a fifth of that present in an equal weight of a sample of fresh 'Marmite'. The ether-soluble extract of the flour was examined spectrophotometrically and was found to contain no vitamin A, but it contained on the average 6·375 mgm. of carotenoids per cent. As regards nicotinic acid (anti-pellagra and anti-blacktongue factor), feeding experiments with dogs showed that it contained a small amount.

Cotton-seed flour is therefore inferior to fenugreek and okra in its protein value, and the vitamin content is not appreciable.

PARTICLE SIZE ANALYSIS

PARTICULATE material is a general descriptive title for the many forms of matter existing in a state of sub-division into discrete particles. Such materials play an important part in almost all human activities, either as dust particles formed by natural agencies, or as powders produced by the artificial reduction in size of larger fragments of material. Dust is always present in the atmosphere, and though generally regarded as a nuisance, also fulfils useful purposes; but when present in excessive quantities it becomes a menace to health, and much active research is in progress to minimize the harmful effects of dust in mining and industrial atmospheres. Artificially ground powders are of the greatest importance to industry; sometimes their production is the main objective, as in the manufacture of Portland cement or pigments, and fine grinding of immense tonnages is an essential stage in the reduction of metallic ores. The building industry uses large quantities of materials in powdered or granular form, and a knowledge of the size analyses of these is essential. Agriculture and civil engineering are concerned with problems such as soil erosion, silt deposition and the foundations of buildings, for which data on the size characteristics of sedimentary deposits are needed. Thus there can be few manufacturing processes which are not dependent upon the use of powdered materials at some stage, and though the quantities involved may be smaller than in the industries mentioned above, the monetary value may be high, as for example in the fabrication of parts from metal powders.

Empirical methods of examination combined with the results of experience have in the past sufficed to determine the quality and the suitability of a powder for a particular industrial purpose, but for the last twenty years considerable attention has been given to methods of particle-size determination. During this period the literature on the subject has grown rapidly in volume; indeed this abundance is somewhat confusing to those commencing a study of methods of particle-size analysis.

A conference was held on February 4 by the Institution of Chemical Engineers and the Society of Chemical Industry (Road and Building Materials Section) with the object of clarifying this situation and summarizing the results of recent researches. The interest in the subject was even greater than expected, for out of an attendance of about 350 persons, quite a large number were unfortunately unable to gain admission to the meeting hall. The conference was divided into morning and afternoon sessions; at the morning session there were six papers dealing with methods of size analysis, and at the afternoon session five papers dealing with industrial applications of sizing analyses, all presented in abstract*. The authors were selected from research workers in Government or Government-aided research laboratories, universities and industrial research departments particularly concerned in the subject. Although clearly impossible to cover every aspect, the papers presented a cross-section of recent developments in particle-size measurement and typical industrial applications. The chairman of the morning session was Mr. Hugh Griffiths, president of the Institution of Chemical Engineers, and the discussion was opened by Dr. Idris Jones, director general of research for the National Coal Board. Dr. Jones directed attention to the importance of particle-size measurements in the coal industry, and emphasized the need for a study of dust-sampling methods. He especially stressed the need for developing a rapid method of size analysis, otherwise there were long delays in applying research to urgent industrial problems.

Dr. L. H. Lampitt, president of the Society of Chemical Industry, took the chair at the afternoon session, and opened the discussion by directing attention to the many applications of particle-size analysis in the food industry. Some thirty speakers contributed to the discussion during the day; many of the comments referred to technical points of detail which will be very helpful in developing research on the subject; but the problem of simplifying the situation for the newcomer to this field of study was scarcely touched. There appear to be three methods that are most promising for the routine measurement of the fineness or state of sub-division of a powdered material. These are the adsorption method of determining surface area, the permeability to fluid flow as a measure of external surface area, and the light-extinction or turbidimeter method of determining particle-size distribution and surface area. The three methods measure different properties of the powder, however, and several speakers directed attention to the need for a co-operative research which would delineate the characteristics of these methods of examination and enable some correlation of the results to be made. This could be done by a comprehensive series of tests on materials of particular importance to industry, and is clearly a subject for future research. The problem of standardization was not dealt with specifically in the discussion; although the British Standards Institution is now engaged in the preparation of standards for the size analysis of certain materials, an extension to cover powdered materials in general would be of great benefit to industrial research workers.

Prominence was given in several of the papers to the definition of terms, with particular reference to aggregates of particles. Much research on the measurement of particle size has been conducted on the assumption that the particles are individual or discrete entities of crystalline nature; indeed, the dispersal of a sample of powder into such a state is one of the problems of analysis. In many practical applications of powdered materials, however, the individual particles are often clustered together in aggregates known as 'working' or 'operational units' which are not physically constant, for the state of aggregation depends on the treatment to which the powder is subjected; for example, it will be different in the dry and wet states, though other factors exert considerable influence. Future research must be devoted to a study of these aggregates and to methods of measurement which indicate the size of these as well as of the discrete particles composing them.

The determination of particle-size analysis is an essential preliminary to the study of many industrial problems involving particulate materials, and much research has been hindered or even wasted by insufficient or incorrect knowledge of this factor. Thus, research on the theory of grinding or on the efficiency of commercial dust filters cannot progress without a knowledge of the size analysis of the materials concerned; and fundamental research on these and many other subjects is impossible until consistent and rapid methods of size analysis have been developed.

---

* The authors of papers were as follows:

Methods of Measurement: C. N. Davies (Industrial Health Research Board, Medical Research Council); Dr. S. J. Gregg (University College, Exeter); Dr. H. Heywood (Imperial College of Science and Technology, London); Dr. F. M. Lea and R. W. Nurse (Building Research Station); Dr. D. G. Skinner and Dr. S. Boas-Traube (British Colliery Owners' Research Association); W. H. Walton (Chemical Defence Experimental Station, Porton).

Industrial Applications: Dr. A. C. C. Newman (Paint Research Station); Dr. R. K. Schofield and Dr. E. W. Russell (Rothamsted Experimental Station); Dr. M. L. Smith (Philips Lamps, Ltd.); C. J. Stairmand (Imperial Chemical Industries, Ltd.); H. Whipp and F. W. Bernhardt (Dussek Bitumen and Taroleum, Ltd.).

This conference was the first of a public nature to be held in Great Britain to consider the properties of powdered materials, and marks an important advance in the study of this branch of applied science. The complete set of papers and the ensuing discussion, both at the meeting and in writing, should become a valuable source of reference on the subject for many years.

HAROLD HEYWOOD

SOCIETY FOR EXPERIMENTAL BIOLOGY

CONFERENCE IN UTRECHT

At the suggestion of Prof. G. J. van Oordt, the Society for Experimental Biology was invited by the botanists and zoologists of the University of Utrecht to hold a conference there during April 11–14. This was a memorable event in the history of the Society, being the first occasion on which a meeting had been held outside Great Britain. Utrecht and its ancient University have been for long associated with the struggle for the freedom of thought in Europe, and, after the recent relief from a period of intellectual suppression, it was a peculiarly happy environment for scientific discussion.

The response to the invitation was much greater than was expected, and the conference was attended by more than eighty members of the Society and about forty biologists from Holland, as well as a few from Belgium. As usual, there were separate botanical and zoological sessions, one in the Botanical Laboratory which, with the adjacent Botanical Gardens, is directed by Prof. V. J. Koningsberger, the other in the Zoological Laboratory, the two main sections of which, devoted to experimental embryology and to endocrinology, are under the direction of Prof. C. P. Raven and Prof. G. J. van Oordt respectively.

Some fifty-five papers were read which covered a wide field, though many centred around subjects upon which active research is now in progress in Holland—phytohormones, absorption of substances by plants, growth and differentiation of animal tissues, and comparative physiology. During a discussion on the possible influence of phytohormones on the fine molecular structure of the plasma membrane, we learnt that the deficiencies in Holland's war-time diet had prevented the secretion into the urine of auxin-*a*, for which the botanists at Utrecht had therefore been compelled to substitute indolyl acetic acid in their experiments on plant growth. Among other interesting subjects discussed in the Botanical Section were the absorption and transport of ions and the influence on this of illumination, the structure of the cell wall, apogamy in ferns and a quantum interpretation of certain data on phototropism. The Zoological Section devoted a morning to tissue differentiation, beginning with the development of bone and widening out into a general discussion on cellular differentiation. Another set of papers on neurophysiology, mostly of vertebrates, but including one on sea anemones, also provided material for good discussion. The rest of the papers were not so closely interrelated, but it was generally agreed that the meetings were stimulating and led afterwards to much informal discussion of these and other subjects of mutual interest to Dutch and British biologists. All communications were read in English and, to our great admiration, the proceedings were in no way hampered by the fact that our hosts were speaking a language in which they have had little practice in recent years.

During the afternoon of April 12, four of the University's Institutes showed demonstrations illustrating their current research. In the Botanical Institute were demonstrations of microdissection, of micro-chemical methods and of hormone test technique. In the Physical Laboratory (director, Prof. J. W. M. Milatz) is a biophysical research group working chiefly on problems connected with micro-organisms and photosynthesis, and here we were also privileged to see one of the few surviving original van Leeuwenhoek microscopes in an interesting demonstration of the history of microscopy. Work on experimental embryology and endocrinology was shown in the Zoological Laboratory; and in the Institute of Comparative Physiology, built in 1936 for the late Prof. Jordan with the aid of the Rockefeller Foundation, the research illustrated was mainly concerned with digestion and with the physiology of invertebrate muscle. This was the only occasion on which members of the Society experienced anything approaching disappointment as, owing to the excellence, number and geographical dispersion of the demonstrations, many were unable to see as much as they would have liked, though this was unavoidable.

The general organisation of the Conference and of its subsidiary functions was excellent, and for this we have to thank the local secretary, Mr. J. C. van de Kamer. In the evening of April 11 the delegates were received in the Central Museum by Dr. G. A. W. ter Pelkwijk, Lord Mayor of Utrecht and curator of the University, and by the director of the Museum, Jonkvr. Dr. C. H. de Jonge; and on the following evening there was a reception in the University by the president-curator, Jhr. Dr. L. H. Bosch Ridder van Rosenthal, followed by a chamber music concert by "The Society for Old Music" of works by Purcell and de Fesch. On Sunday, April 13, we were the guests of the Dutch Government in an excursion through North Holland to the Zuider Zee Dyke, and one of the chief engineers, Jr. Volker, and Mr. Botermans from the Governmental Department of Information, kindly acted as guides and explained some of the hydrological and biological problems connected with land reclamation.

By the generous invitation of one of the students' committees of the University of Utrecht, members of the conference were permitted to use as meeting-places and restaurants one of the clubs of the Utrechtsch Studentencorps, and a club of the Utrechtsch Vrouwelyke Studenten Vereeniging. This not only added greatly to the comfort and enjoyment of the proceedings, but also enabled us to understand how the Dutch have successfully solved the problem of a traditional corporate life in a non-residential university. But it must be especially emphasized that nearly all the eighty members of the conference were lodged and entertained in the homes of the University staff and of other professional people in the neighbourhood. In the present very difficult circumstances this is hospitality indeed; and one of the most significant features of the conference was the open hearted demonstration of personal and informa friendship which made the occasion one of much more than purely scientific value. This kind of atmosphere is perhaps less easily created at an ordinary international conference, and we hope that this will not be the last occasion on which a scientific society is invited to hold a meeting in another country.

L. C. BEADLE

MOUNT HOPE AND ITS DAIRY CATTLE

THE increase of milk production is one of the desiderata that is commonly accepted as necessary, and one of the equally commonly accepted ways of securing an increase is by the use of a proven sire. This is the more necessary because it has been said by no less an authority than Robert Boutflour that the average production during a lactation is little, if any, more to-day than it has been for a very long time.

It is to this end that the Mount Hope Farm was established, and a complex of investigations into the laws of inheritance among mice, poultry and dairy cattle began. Mr. Parmalee Prentice has now described these investigations (*Agric. History*, Oct. 1946). The work with dairy cattle started in 1916 when the first were bought, but contagious abortion delayed the start of real work on breeding until the herd had been purged of this disease, by which time (1924) a young Guernsey herd had been acquired which was thought likely to be good. For various causes a satisfactory bull did not appear, and in 1925 a bull was bought because he ranked well according to the system of valuing dairy bulls developed at the Maine Agricultural Experiment Station. This system is based on a comparison of a bull's mates and of his daughters; if the daughters' milk yield was higher the bull was advantageous, if lower the bull was detrimental. The amount of the increase was considered to be a measure of the bull's influence on milk yield.

Misfortune followed the choice, for the bull became impotent and a new bull was selected on the Turner measure for proven sires; but this was found unsatisfactory, and this particular system is no longer used "because it has been found that it over-estimated the inheritance which the sire contributed to its offspring"; and Mr. Parmalee Prentice and his coworkers found it conceivable that the daughters of this bull were good "not only because his influence was good but also because their dams had contributed as much as the sire"—which seems not unreasonable.

They then proceeded to work out a system of their own which they named the Mount Hope 'index', "a correct method of determining a bull's breeding worth from his daughters' records after allowance is made for the dam's influence upon the daughters' productivity". The index was first announced in 1927 and has now been before the world for twenty years.

"Bull indexes are computed by comparing the production records of the daughters and mates of the bull. In order to compare the production of the daughters with the production of their dams and to make comparisons between other cows of different ages, our statistics of milk production since 1936 . . . are always in terms of the mature equivalent. The index is then always applied to a comparatively small number of dam-daughter pairs. Moreover seasons vary; food and management are different in different barns and frequently change in the same barn. The physical condition of the cattle varies, and the result of it all is that though we are able with assurance to tell a good cow from a poor one and in general to tell how good a particular cow is, we are never able in measuring production records to tell with scientific precision the productive ability of a particular cow."

In many places the Mount Hope index has been accepted and is being used. In others, and perhaps the majority, the index is regarded with some scepticism. The need for proven sires and the sons of proven sires in dairy cattle breeding is fairly generally accepted, and records have been adopted so that performance may rank alongside 'pedigree'—one of the qualifications of which the Mount Hope workers are most critical. There has been a good deal of controversy about the Mount Hope dairy cattle and the Mount Hope index, and the essay by Mr. Parmalee Prentice in *Agricultural History* of October 1946 tells the whole story of the work that has been done there. The quarterly is the organ of the American Agricultural History Society, the offices of which are at Room 3870, South Agricultural Building, Washington 25, D.C.; and the annual subscription is four dollars.

G. E. FUSSELL

RELEASE OF INFORMATION ON ATOMIC ENERGY*

THE National Research Council of Canada is making available a number of reports, recently taken off the secret list, on subjects in the fields of theoretical physics and applied mathematics. These reports, which are either too long for journals or are summaries of other work, will be reproduced by the multilith process and will be available at a small charge from the Plans and Publications Section of the National Research Council, Ottawa.

Much material in the hands of the Council is being published in Canadian scientific journals, but the titles mentioned below represent a few which for special reasons cannot be dealt with in that way.

LIST OF DECLASSIFIED REPORTS

MT-1	The Functions $E_n(x) = \int_1^\infty e^{-xu}u^{-n}dx$	G. Placzek
MT-12	Elementary Approximation in the Theory of Neutron Diffusion	P. R. Wallace and J. LeCaine
MT-4	Notes on Diffusion of Neutrons without Change in Energy	G. Placzek and G. Volkoff
MT-131	A Table of Integrals involving $E_n(x) = \int_1^\infty e^{-xu}u^{-n}du$	J. LeCaine
MT-88	Influence of a Small Black Sphere upon the Neutron Density in an Infinite Non-Capturing Medium	B. Davison
MT-232	Influence of an Air Gap surrounding a Small Black Sphere upon the Linear Extrapolation Length of the Neutron Density in the Surrounding Medium	B. Davison
MT-93	Influence of a Large Black Sphere upon the Neutron Density in an Infinite Non-Capturing Medium	B. Davison
MT-112	Angular Distribution due to an Isotropic Point Source and Spherically Symmetrical Eigen-Solutions of the Transport Equation	B. Davison
MT-135	Influence of a Large Black Cylinder upon the Neutron Density in an Infinite Non-Capturing Medium	B. Davison
MT-124	Large Spherical Hole in a Slightly Capturing Medium	B. Davison
MT-136	Neutron Density at the Centre of a Small Spherical Cavity	B. Davison

* British declassified reports are announced in *Nature*, March 22, p. 411.

FORTHCOMING EVENTS

*(Meeting marked with an asterisk * is open to the public)*

Tuesday, May 27

University College (in the Anatomy Theatre, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. Maurice Caullery: "Marine Biology on the French Coast in the Last Hundred Years".*

Wednesday, May 28

Institute of Fuel (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Dr. E. A. Watson and Dr. J. S. Clarke: "Combustion and Combustion Equipment for Gas Turbines".

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 5 p.m.—Sir Harold Spencer Jones, F.R.S.: "Modern Astronomical Instruments" (Trueman Wood Lecture).

Society of Chemical Industry, Chemical Engineering Group (at the Waldorf Hotel, Aldwych, London, W.C.2), at 5.30 p.m.—Annual General Meeting.

Institution of Electrical Engineers, London Students' Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 7 p.m.—Annual General Meeting.

Thursday, May 29

Royal Statistical Society (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.15 p.m.—Dr. M. S. Bartlett: "Multivariate Analysis".

Royal Aeronautical Society (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 6 p.m.—Mr. J. K. Northrop: The Thirty-fifth Wilbur Wright Memorial Lecture.

Television Society (at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W.C.2), at 6 p.m.—Dr. D. Starkie: "Plastic Lenses in Television Projection".

Friday, May 30

Physical Society (in the Physics Department of Imperial College, Imperial Institute Road, London, S.W.7), at 5 p.m.—Scientific Papers.

Saturday, May 31

British Psychological Society (in the Physiology Theatre, University College, Gower Street, London, W.C.1), at 10.30 a.m.—"The Film in Education".

Tuesday, May 27—Saturday, May 31

Textile Institute (at Portrush, Co. Antrim).—Annual Conference. "Developments in the Production and Processing of Textiles."

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer in Physical Chemistry, a Lecturer in Pharmaceutical Chemistry, a Lecturer in Metallurgy, a Lecturer in Physics, and a Lecturer in Biology—The Registrar, College of Technology, The Newarke, Leicester (May 31).

Senior Assistant in the Mechanical Engineering Department, and a Lecturer in Mathematics and Physics, at the Rutherford College of Technology—The Director of Education, City Education Office, Northumberland Road, Newcastle-upon-Tyne 1 (May 31).

Lecturer in Chemistry and Metallurgy—The Registrar, Technical College, Sunderland (May 31).

Chair of Physiological Chemistry—The Secretary of the University Court, The University, Glasgow (May 31).

Senior Lecturer in Mathematics—The Principal, Chelsea Polytechnic, Manresa Road, London, S.W.3 (May 31).

Head of the Department of Chemistry and Dyeing, Bradford Technical College—The Director of Education, Town Hall, Bradford (May 31).

Science Lecturer to teach at least two of the following subjects: Biology, Chemistry, Physics, Mathematics, a Modern Language—The Principal, Aston Technical College, Whitehead Road, Birmingham 6 (May 31).

Readership in Medical Parasitology at the London School of Hygiene and Tropical Medicine—The Academic Registrar, University of London, Senate House, London, W.C.1 (June 2).

Graduate Teachers (2) to take courses up to Higher Certificate standard in (*a*) the Mechanical Engineering Department to teach subjects of Heat Engines, Strength of Materials, Theory of Machines, and Drawing and Design; and (*b*) the Electrical Engineering Department to take all subjects, including Mathematics—The Secretary, School of Engineering and Navigation, High Street, Poplar, London, E.14 (June 5).

Lecturer (Grade III) in Geography—The Registrar, Queen Mary College, Mile End Road, London, E.1 (June 7).

Lecturer to teach Physical Chemistry—The Registrar, University College, Hull (June 7).

Physicist to assist in research on application of physics in medicine, and a Junior Physicist to take part in clinical, teaching and research work—The Secretary, Royal Cancer Hospital (Free), Fulham Road, London, S.W.3 (June 9).

Lecturer (Grade I) in Mechanical Engineering, and a Lecturer (Grade I) in Electrical Engineering—The Principal, Heriot-Watt College, Edinburgh (June 9).

Inspector of Explosives—The Secretary, Civil Service Commission, 6 Burlington Gardens, London, W.1, quoting No. 1878 (June 14).

Lecturer, and Demonstrators (2), in the Department of Chemical Pathology, and an Assistant Lecturer in Pharmacology—The Dean, Guy's Hospital Medical School, London, S.E.1 (June 14).

Assistant Lecturer in Chemistry, and a Lecturer (Grade II) in Botany—The Registrar, University College, Southampton (June 14).

Scientific Assistant—The Director, School of Agriculture, Cambridge (June 14).

Assistant (full-time), and an Assistant (part-time), in the Department of Psychology—The Secretary, Bedford College for Women, Regent's Park, London, N.W.1 (June 14).

Assistant Lecturer (man or woman) in Agricultural Chemistry—The Registrar, Wye College, Wye, Ashford, Kent (June 14).

Lecturers in Agriculture, Agricultural Chemistry, Agricultural Zoology, Mechanical Engineering, Civil Engineering, Botany, Chemistry, Pathology and Bacteriology, Anatomy, Physiology and Histology, Surgery and Medicine, for Gordon Memorial College, Khartoum, Sudan—The Secretary, Inter-University Council, 8 Park Street, London, W.1 (June 15).

Chair of Physiology, a Lecturer in Special Sense Physiology, and a Lecturer in Histology—The Registrar, University College of South Wales, Cathays Park, Cardiff (June 15).

Assistant Lecturer (Grade III) in Mathematical Physics—The Secretary, The University, Edmund Street, Birmingham 3 (June 15).

Lecturer in Romano-British Archæology—The Registrar, The University, Leeds 2 (June 15).

Senior Physical Metallurgists (2), and Metallurgical Technicians (2), by the Department of Scientific and Industrial Research, New Zealand—The High Commissioner for New Zealand, 415 Strand, London, W.C.2 (June 15).

Lecturer in Chemistry—The Registrar, Trinity College, Dublin (June 15).

Lecturers (2) in Mathematics in the Natal University College—The Secretary, Universities Bureau of the British Empire, 8 Park Street, London, W.1 (June 16).

Chair of Child Health—The Secretary, The University, Aberdeen (June 16).

Assistant Lecturers (2) in Botany (preferably with experience in Cell Physiology or Anatomy)—The Registrar, The University, Manchester (June 16).

Lecturer (Grade II) in the Department of Inorganic and Physical Chemistry—The Registrar, The University, Liverpool (June 20).

Lecturer (Grade II) in Genetics—The Registrar, University College, Southampton (June 21).

Lecturer in Mathematics, or an Assistant to the Professor—The Registrar, Trinity College, Dublin (June 21).

Lecturer in Mechanical Engineering—The Registrar, Queen Mary College, Mile End Road, London, E.1 (June 23).

Chair of Geography at Birkbeck College—The Academic Registrar, University of London, Senate House, London, W.C.1 (June 25).

Readership in Organic Chemistry at Birkbeck College—The Academic Registrar, University of London, Senate House, London, W.C.1 (June 26).

Assistant Lecturer (Grade III) in the Department of Geography—The Secretary, University College, Gower Street, London, W.C.1 (June 30).

Assistant Lecturer (Grade III) in Geology—The Secretary, The University, Edmund Street, Birmingham 3 (June 30).

I.C.I. Research Fellowships in Physics and Chemistry, including Physical and Organic Chemistry, Biochemistry, Chemotherapy and Pharmacology—The Secretary, The University, Edinburgh (June 30).

Assistant in the Civil and Mechanical Engineering Department—The Secretary of the University Court, The University, Glasgow, W.2 (June 30).

Chair of Architecture—The Acting Registrar, The University, Sydney, Australia (July 31).

Senior Technician for Physics Department—The Secretary, Mount Vernon Hospital and the Radium Institute, Northwood, Middx.

Lecturer in the Department of Mathematics, and Lecturers in the Department of Applied Chemistry—The Secretary, Northampton Polytechnic, St. John Street, London, E.C.1.

Technical Research Assistant by the Professor of Physiology—The Secretary, King's College of Household and Social Science, Campden Hill Road, London, W.8.

Assistant Lecturer in Physics—The Secretary, Royal Technical College, Glasgow.

Scientific Officer (Electrical Engineering and Instrumentation, temporary) at the Atomic Energy Research Establishment, Harwell, Didcot, Berks.—The Secretary, Ministry of Supply, Est.8C, Room 193, Shell Mex House, Strand, London, W.C.2.

Laboratory Assistant in the Department of Zoology—The Secretary to the Governors, Royal Holloway College, Englefield Green, Surrey.

Chief Instrument Maker for Natural Philosophy Department—The Professor of Natural Philosophy, Royal Technical College, Glasgow.

Experimental Officer for testing dairy plant and equipment—The Secretary, National Institute for Research in Dairying, Shinfield, Reading.

Lecturer in the Engineering Department, and a Lecturer to teach Physics to the standard of Intermediate B.Sc. and some Mathematics—The Principal, County Technical College, Guildford, Surrey.

Assistant to teach Chemistry in the Technical Day School, and up to Intermediate B.Sc. degree standard in the Technical College—The Principal, Technical College, West Hartlepool.

Scientific Assistants (male or female) by the Ministry of Supply for chemical work, mainly of an analytical nature, at the Ministry of Supply Factory, Springfield, near Preston, in connexion with the Atomic Energy Production programme—The Appointments Officer, Ministry of Labour and National Service, 1–6 Tavistock Square, London, W.C.1, quoting K.S.337.

PAPER SHORTAGE, EDUCATION AND RESEARCH

THE debate on the book publishing trade in Great Britain which took place in the House of Commons on the adjournment on May 9 reflected general disquiet on the subject. The position had previously been the subject of letters to the Press by Sir Stanley Unwin and others, and of questions in the House of Commons itself, replies to which from the Government had not given satisfaction. The shortage of paper supplies existed before the fuel crisis, and the unsatisfactory position in regard to scientific and technical books was discussed in *Nature* of December 28. Sir Stanley Unwin in a letter to *The Times* stressed the way in which even Government departments as well as the schools and colleges have now become handicapped by the scarcity of books, and referred to the inability of publishers to meet the insistent demand abroad for British books, which can be looked upon as valuable contributions to the country's export target and also as a means for promoting knowledge of the British way of life.

These three points were brought together in the motion cited by Mr. Wyatt, which urged the Government to accept the principle that book publishing is an essential industry deserving a greater and more appropriate measure of priority in view of its importance to the culture of the country and to the export trade, and the necessity of maintaining and increasing the provision of text-books for schools and universities. Mr. Wyatt urged that the small amount of coal and paper consumed in book publishing is out of all proportion to the immense value to the community of books produced. Not more than about 2·5 per cent of the paper used in Britain goes to book publishers; Mr. Wyatt pointed out that 71,000 tons a year was consumed by the Stationery Office as against only 54,000 tons in 1946 by all the book publishers together. It is at present quite impossible to replace ordinary standard works to make good the ordinary wear and tear of libraries, quite apart from the replacement of copies destroyed during the War. All reserve stocks of paper for books, particularly school-books, have been used up, and with their present paper quota publishers cannot possibly begin to make up the present deficiency of books for schools or colleges, or of recognized classics, and at the same time continue publishing as a live industry.

The demand is, of course, greatly accentuated by the raising of the school-leaving age, the expansion of the universities and the increased demand of the public for reading matter which has grown up during the War. While every university or public library can bear witness to the intense and largely unsatisfied demand for text-books of all classes, including the set books for examinations, and to the number of students whose needs are not met, Mr. Wyatt pointed out that another serious feature of the situation is that the culture of the country is being stifled because publishers cannot publish the works of new authors. Mr. Wyatt, after referring also to the export trade and to the prestige value of British books abroad as more important than the financial aspect, emphasized particularly the way in which the sale of technical books abroad is being captured by the United States. The output of British scientific and technical books during recent years has been low enough, but Mr. Wyatt pointed out that because we cannot export our books, American publishers are buying the copyright to export them themselves, and their export trade in books has already risen from about £1,500,000 a year to three times that figure. Not only are books completely overlooked in the matter of priorities, but also the paper salvage drive is being neglected.

The debate itself illustrated the lack of appreciation of the position on the part of the Government, for the time allowed no other speeches than those of Mr. Wyatt and Mr. Belcher, Parliamentary Secretary to the Board of Trade, in reply. Mr. Belcher, who maintained that the Government does consider books an important part of the life of the country, urged that the position is not entirely due to lack of fuel: there is a twenty per cent. deficit of labour in the printing and bookbinding trades, and machinery has suffered from seven years depreciation and lack of replacement, apart from the destruction of about 5,000 printing machines during the War. Replacements will take from one and a half to two and a half years; the greatest problem, he said, is bookbinding machinery, which the Government is now arranging to import from the United States. Last winter, publishers were allocated 80 per cent of their pre-war consumption of paper, with an additional 10 per cent for export; and when, following the fuel crisis, it was agreed with the Publishers' Association to reduce the 80 to 70 per cent, the Government undertook to license in a subsequent period supplies to make up any deficiency on the 70 per cent in any one period. The coal allocation was increased from 33⅓ in March to 50 per cent in mid-April, and from June onwards the mills will receive an allocation of fuel equal to their full consumption in the summer of 1946. Paper supplies should therefore, according to Mr. Belcher, shortly reach the level anticipated before the fuel crisis, and the Government has made arrangements under which book publishers will receive a basic allocation of 60 per cent of pre-war consumption. In addition, they will be allowed 20 per cent, provided they devote the same proportion as before of their 60 per cent quota to educational or export books, and give an undertaking that they will use the additional 20 per cent for increased production of educational books for use in schools, colleges and universities and for home study, or for increasing their export targets. If, in the future, the amount of paper for book publishing were increased, the Government would hope to maintain these arrangements, with proportionate increases in the 60 per cent and 20 per cent figures. Mr. Belcher added that arrangements already made for publishers to receive from the special reserve of paper extra allocations for the production of essential books which they are unable to produce from their own quota would continue, and the Government has decided to divert from the reserve 1,000 tons for the production of educational text-books.

Much turns on the use of the term 'allocation'; in this connexion it means 'permission to buy' and is in no sense a guarantee that supplies will be obtainable. Further, the reference to the special reserve of paper, better known as the 'Moberley pool', is obscure; this reserve, of 1,500 tons, was established for the production of cultural and educational books, subject to detailed inquiries, and it is not apparent what change in policy is intended.

Moreover, there were several points raised by Mr. Wyatt and Sir Stanley Unwin to which no reply was made. The point about exporting paper, and particularly coated papers, was ignored; and Mr. Belcher in his reference to machinery did not indicate that the industry is to receive any priority in the replacement of worn-out machinery or in the allocation of raw materials. It is, in fact, the ignoring of this claim to priority and the absence of imagination in Mr. Belcher's reply which are the most disturbing features of a situation in which the virtual embargo on the output of new literature and of scientific and technical books is likely to persist.

Mr. Belcher may have dismissed the idea of salvage too lightly, and more might be done in the way of paper economy in the myriad fields in which paper is used in a modern community. It is, however, the manifold nature of those uses and the complex way in which they are entangled with almost every aspect of the life of the citizen—business, industrial and civic, as well as educational and cultural—that makes it so important that supplies should be brought to an adequate level as a priority of the first importance to every section of the community and every aspect of national life.

Here we cannot allow to pass unchallenged the question of the production of scientific and technical books. Apart from the fact that, as Mr. Wyatt pointed out, the sale of British technical books abroad tends to stimulate the sale of the British machinery and equipment described in such books and from the prestige element attached to sales abroad of such books, it is not altogether desirable that scientific men and technologists in Great Britain should be so largely dependent on books from other countries in their work. Scientific and technical advance in Britain might well be assisted if an attempt could be made to restore the balance which seven years of preoccupation with the demands of war has upset. British achievements and advances should be made known to the world at least in part by the men responsible, and also in books produced in Great Britain.

There is a further factor which was most evident at the time of the fuel crisis in the suspension of scientific and technical periodicals, but which, as was pointed out at the time, is an inevitable consequence of the shortage of newsprint. Scientific work and interests, as well as knowledge of public affairs, are liable to suffer from the compression and selection that are involved when newspapers and periodicals are severely limited in size. Scientific and technical factors themselves are often involved in the formation of sound public judgments on such matters as the fuel crisis, even though the problem appears as first sight to be purely political. Lord Marley, for example, pointed out in the House of Lords how neglect to apply available knowledge resulting from scientific research into fuel problems had contributed to the fuel shortage. His criticism was directed against sections of industry as well as against the Government itself; but if sound policy is to be evolved and appropriate administrative action taken, it is important that scientific and technical opinion should have the opportunity to express itself effectively before policy has been determined. The point is the more important because there are indications that measures of rationing contemplated are of the type that penalizes the efficient consumer, whether individual or industrial, and those who have responded most loyally to the appeal for economy.

The suspension of the scientific and technical Press of the country was a serious hindrance to the expression of informed, responsible and constructive criticism on certain highly important aspects of the situation, and in that alone was a threat to what is usually understood by 'the freedom of the Press'. Nor is that all. While in the technical field to which we have just referred, the ability of the engineer, the chemist, the physicist, the fuel technologist, and others to express sound judgments is unquestioned, there are also fields, such as that of management and administration, where the scientific worker and technologist have not only the duty to express an opinion when they can do so from personal knowledge and experience, but also where they may often be at least as competent to utter sound judgments as their fellow citizens. Only the most outrageous casuistry can pretend that behind the immediate physical difficulties which precipitated the fuel crisis and the long series of handicaps which the Government inherited from the past, there has not been the human contributory factor of procrastination and inept administration.

Scientific workers or technologists cannot be expected to make their due contribution to social and public affairs if arbitrary action such as occurred in the fuel crisis is allowed to obstruct informed comment and responsible criticism. It cannot be denied that the situation which involved the suspension of periodicals was preventable, and with reasonable foresight and competent administration would not have arisen. As the Commission on Freedom of the Press in America points out in a general report entitled "A Free and Responsible Press", if freedom of the Press is to achieve reality, Government must set limits upon its capacity to interfere with, regulate, control, or suppress the voices of the Press, or to manipulate the data on which public judgment is formed; and it goes on to point out that without intruding on press activities the Government can even help to improve the conditions under which such activities occur, and remove hindrances to the free flow of ideas instead of thwarting that flow, and promote, instead of check, the reality of public debate.

Freedom of the Press is indeed no less essential to scientific advance than to political liberty and to the creative activities on which the spiritual life of men depends. Where, as the Commission observes, men cannot freely convey their thoughts to one another, no freedom is secure. Moreover, science itself is a part of that civilized society which is a working system of ideas; and like it, lives and changes by the consumption of ideas, and can only indeed serve the society of which it forms a part by ensuring that as many as possible of the ideas of its members are available for examination by the scientific method, and that the results of scrutiny are fully and freely made known to society. That is the fundamental reason why the scientific worker as such is bound to protest against restrictive administrative action; this applies whether the action is due to lack of imagination as in the question of paper supply for books, or to the failure to observe in the fuel crisis the restraints which, as the American Commission insists, a democratic government is morally bound to respect in all circumstances.

PHILOSOPHY AND ITS BACKGROUND

History of Western Philosophy and its Connection with Political and Social Circumstances from the Earliest Times to the Present Day

By Bertrand Russell. Pp. 916. (London: George Allen and Unwin, Ltd., 1946.) 21*s.* net.

If one grants the assumption as to the nature of philosophy on which this book is based, it is a remarkable achievement. The assumption is, as Lord Russell says in the introduction, that philosophy is something intermediate between theology and science; it is a no-man's-land; it is speculation about the nature of the universe and the nature of things, based on the assumption that you can get definite answers on such subjects by speculation. Lord Russell does not think that you can do this, but the belief in the powers of such speculation has persisted and has produced many interesting results.

Western philosophy so conceived begins, not with Socrates but with Thales, and what this book does is to review the long history of men's speculations from Thales to the present day. The views of the philosophers are described with the beautiful lucidity of which Lord Russell is a master, and as he describes the views of one philosopher after another he adds witty, waspish, cynical and wise comments. If Edward Gibbon had been a philosopher instead of a historian, he might have produced a book very like this. It is a curious history because, according to Lord Russell, it has been all wrong. We have now, at long last, discovered that this speculation is vain. The answer to that effect has been finally and conclusively given by logical positivism. Yet I think that Lord Russell would still have us study philosophy, because he discerns as a by-product of this curious, mistaken activity a certain emotional temper, a certain contemplative attitude towards the world which he thinks is of great value.

Lord Russell makes a point of accompanying the accounts of the speculations of the philosophers with a statement of the historical background from which these speculations came. It appears to me that the idea is sound and valuable, but I cannot think much of the execution. I do not think that Lord Russell is a historian. The history is accompanied by interesting and illuminating comments, but some of it seems to me just the expression of Lord Russell's dislike, and not history at all. One has only to compare, for example, the chapter on "Die Anfänge des Judaismus" in Edward Meyer's "Geschichte des Altertums" with Lord Russell's chapter on the Jews to see what poor stuff the latter is. What is more curious is that Lord Russell does not really connect the history with the philosophy. His account of the philosophers is curiously unhistorical. He examines the work of one of them after another, selects the propositions which they believe to be true and which interest him, compares them with his own views, all as though they were contemporaries and not in the least as though their philosophy was integrated with, or really part and parcel of, the historical time in which they were living. It surprises me very much that anyone can discuss Socrates without describing the crisis through which Athens was passing in the fifth century as told, for example, by Thucydides. He writes of these various Greek philosophers of that time as though they were interesting and brilliant people who happened to turn up then, but who were not, as people, really concerned about the state of their civilization. All that Lord Russell does with the historical side is to show that this aloof, contemplative, speculative faculty as it appears in one man after another is to some extent influenced by historical events. I do not think he does anything like justice to the real interpenetration of philosophy and history. But that again is the result of his conception of what philosophy is.

One result of this conception of philosophy is that it confines philosophy to logic and metaphysics. There is nothing about the philosophy of history, and therefore not a word, in the modern section, about Vico or Croce or Dilthey. Similarly, there is nothing about æsthetics, and, most significant omission, philosophy does not include moral philosophy. Of course, Lord Russell has to make remarks about the moral views on philosophy held by Socrates, for example, or Locke; but he does not pay very much attention to them; they are not his concern. It is to me, therefore, no accident that Lord Russell seems to take a very unfavourable view of Socrates and Plato and, more especially, of Emanuel Kant, for their conception of philosophy was entirely different from his.

Perhaps the easiest way to put the point I want to make is to ask why earlier historians of philosophy have always held that Greek philosophy began with Socrates. They all, of course, recognized that the so-called pre-Socratics had something to do with philosophy; they held, nevertheless, that philosophy proper began with Socrates. The explanation is that Socrates was not just concerned with what Lord Russell regards as philosophical questions; he was concerned with the problem of standards in general. Socrates thought that Athens was going to pieces because the democracy of the day repudiated moral and political standards. He was sure that there were such standards, and he made it his business to examine and vindicate them. He did so very largely by directing attention to the existence of scientific standards in mathematics and by asking himself what was the relation between moral standards, or 'the just', and mathematical standards. Plato's theory of forms, which was an elaboration of Socrates, was not just a theory of universals; it was a theory of standards. Plato, for example, did not think there was a form of green; for we do not conceive of there being a green which is greener than any visible green. Socrates began by comparing the political teachers of the time unfavourably with craftsmen. The craftsmen at least knew the difference between good and bad work. The mathematicians knew the difference between mathematical thinking and vague guessing and purely empirical measuring. The recognition of the fact that there are good and just men as there are bad and unjust men is, to Socrates and Plato, and, for that matter, to Aristotle, a fundamental fact that has just got to be reckoned with. What philosophy does, as Plato explains in the Republic, is to reflect on the assumptions and hypotheses of the different inquiries and to consider their relation to one another. Such reflexion is clearly not in vain; it is very concrete and very definite. Of course, such reflexion on the nature of standards may, and in Plato does, result in conclusions which Lord Russell would call speculative. There is a very great division which runs through philosophy, conceived in the Platonic or Kantian sense, between those who hold that reflexion on assumptions and hypotheses leads to an apprehension of supersensible realities, and those who do not. Dialectic for Plato leads to such apprehensions; for Aristotle it is a form of false reasoning; for Hegel it is the highest form of knowledge; for Kant it is illusion. But that does not alter the fact that all these philosophers begin with the solid facts of human achievement, with the facts of right thinking and good conduct and fine art and just government.

This contrast I have been trying to make comes out more strikingly than ever if you compare Lord Russell's treatment of Leibniz with his treatment of Kant. Leibniz is, perhaps, his favourite philosopher and he puts him very high. Leibniz had an extraordinarily ingenious speculative mind, and, in my judgment, no sense of reality whatever. But he could perform to perfection the kind of ungrounded speculative thinking with which Lord Russell identifies philosophy. When Lord Russell comes to Kant he explains that he does not think much of him: of that one cannot complain; but the extraordinary thing is that he considers Kant's most important contribution to be his view of space, a view taken by Kant in his pre-critical period; and what Kant regards as his far-reaching discovery, that metaphysics should be criticism, is not expounded or examined. Kant is not a speculative philosopher; he does not believe in speculative philosophy. He started with his feet most firmly on the ground, with being quite certain that there was all the difference in the world between science properly so-called and what he describes as "groping around"; between doing what you ought and doing what you happen to like; between great art and finding what would tickle the public; and he sets himself to ask how these great achievements of the human spirit were possible, how alike or how different they were in methods and assumptions and what they implied.

Those seem to me to be the two main ways of regarding philosophy. I entirely accept the Kantian revolution, and therefore I cannot be expected to have much sympathy with Lord Russell's pre-revolutionary conception. But, as I said at the beginning of this review, if you do accept Lord Russell's assumption as to what philosophy is, this is a very remarkable performance. For those who like this sort of thing, this is indeed the sort of thing they like.

LINDSAY OF BIRKER

CAUSAL FACTORS IN SCHIZOPHRENIA

The Biology of Schizophrenia

By Dr. R. G. Hoskins. Pp. 192. (New York: W. W. Norton and Co., Inc.; London: Chapman and Hall, Ltd., 1946.) 15*s*. net.

THE greatest problem of modern psychiatry is that of schizophrenia. The vast majority of the permanent occupants of the mental hospital consists of patients suffering from this disease, which besides cripples a large number of patients who contrive to live a precarious existence in the outside world as tramps, eccentrics, prostitutes and similar misfits.

Dr. Hoskins' book is a valuable review of this psychosis. It is an expanded version of his three Salmon Lectures. The first part is devoted to a description of the development of human personality and social community on the basis of emergent evolution. The second part is a description of schizophrenia as a pattern and the comparison of it with various biological reactions found in other animals. It is the third part which will be of most interest to the clinical psychiatrist and the research worker. In this part he reviews a large amount of modern literature and examines the various possible causes for the curious symptoms which characterize this disease. He examines the endocrine factors, the oxygen relationships, the carbohydrate metabolism, the circulatory conditions and the importance of hæmostasis. Many of the facts which Dr. Hoskins discusses here have been determined by his own research team at Worcester State Hospital.

It is obvious that in research upon an obscure disease process such as schizophrenia there is no one method of approach; but it is rather the correlation of the multitudinous minor discoveries which will give the final clue. Dr. Hoskins wisely takes the biological stand and attempts to fit together what is known; but unfortunately not enough has yet been discovered to make it possible to solve the problem. He seems to think that the avenues of research tend to lead towards the problem of maturation as related to the endocrines, vitamins and enzymes. He points out that the schizophrenic is lacking in empathy (the basis of emotional relations with others), and that if we could discover the cause of this deficiency we should be advancing our chances of solving the whole problem. In this matter he points out that feral children—children who have been adopted by wild animals since an early age—are totally lacking in power to show empathy. He suggests the importance of inheritance by quoting the well-known work on twins, in which it was shown that if one of monozygotic twins developed schizophrenia this also tended to appear in the other, while dizygotic twins did not show similar reactions.

Dr. Hoskins shows an easy tolerance to all schools of psychiatry and writes fairly and generously from all points of view. His style is clear and understandable—a virtue not always found in psychological books. The format itself is excellent, the print is clear, with wide margins such as have not been seen in Britain since the paper shortage. The binding is good. There is a long list of references, which are valuable to those who wish to read one particular part of the literature, and there is an excellent index.

Clifford Allen

A BIRD PHOTOGRAPHER ABROAD

Bird Life in Two Deltas

Being the Diaries of a Bird Photographer in the Estuaries of the Guadalquiver and the Rhone and their Neighbourhoods. By G. K. Yeates. Pp. 159 + 68 plates. (London: Faber and Faber, Ltd., 1946.) 15*s*. net.

THE standard of bird photography has risen high in recent years, but we have no better exponent of the art, for an art it has become, than G. K. Yeates. His bird portraits are superb examples of the work of the camera. In his latest book, "Bird Life in Two Deltas", we see pictures taken in Spain and in the south of France. "The Spanish *marismas* at the estuary of the great Guadalquiver and the Camargue or Rhône-Delta constitute two of the greatest bird paradises in Western Europe", says the author. He goes on, "The brief visits of a foreigner to these great oases of bird-life, so vast that even a lifetime would leave much unseen and unexplored, can in themselves provide only a fleeting glimpse into the wealth and variety of their natural history. These three diaries which follow are the unadorned records of my visits."

But the diaries, if 'unadorned', are not the less interesting for that, for they tell a plain story very well, the story of a naturalist in a rich field, of his difficulties, his triumphs and his many observations. Here is his account of flamingoes: "Never have I been so moved by the sheer wondrous beauty of a bird as I was today by these flamingoes. . . . We first saw the birds as a long thin pink line through the mirage. As we came closer, they assumed more definite shape. When wading through the shallows, the flamingoes' general colour scheme is a very soft pink. The body appears like a round ball precariously balanced on two long pink stilts. The long thin serpentine neck with the curious heavy downward-tilted bill completes a strange picture. . . . The soft reflections of the long thin pale-pink line in water that took its colour from the blue of the sky defeat my poor pen for description."

Yeates adds: "Lovely as is the flamingo as it wades, it is a flash of glory on the wing, for then instead of the soft pinks which predominate on the ground the bird exposes the brilliant scarlet of the covert feathers . . . nor is it just one bird in the air. Numbers on such a scale are difficult to estimate, but I do not think 1,500 far short of the birds that were here present."

Buff-backed herons, little egrets, black-winged stilts, night herons, hoopoes, etc., provide the author with many observations on bird behaviour and with photographs of remarkable quality.

Of special interest are his records of the penduline tit in the act of constructing its nest. Photographs of nest-building are rare. This species contrives a lovely little domed nest after the style of that of the familiar long-tailed tit, but uses reed 'down' instead of moss and lichen. A favourite site is among the drooping sprays of tamarisk. We here see stages in the building, an outer circle or hoop being first constructed, in which the bird works and builds up the main walls.

Several useful appendixes are to be found at the end of the book—a bibliography which will be helpful to anyone desiring to look up the literature of these bird paradises, a list of scientific names and a list of the French names of the Camargue birds.

BRITISH SCIENTIFIC INSTRUMENTS

PHYSICAL SOCIETY'S EXHIBITION

THE healthy condition of the British scientific instrument industry was again demonstrated at the second post-war exhibition held by the Physical Society at the Imperial College of Science and Technology, South Kensington, at Easter. In the past it has been customary to hold the exhibition early in January, but owing to the extraordinary and unforeseen large increase in attendance at the first post-war exhibition (held January 1946), it became necessary to make fresh arrangements. These took the form of a restriction in the number of tickets issued (limited to about 12,000), an increase of the floor space of the exhibition (extending into a part of the Science Museum), and an increase in the period during which the Exhibition was open, from three to four days (April 9–12 inclusive). It was mainly due to this latter change that the Exhibition, the thirty-first of the series, was held at Easter instead of the New Year. These changes certainly had the desired effect, and visitors this year were able to view the splendid display of scientific instruments under relatively comfortable conditions.

Owing to paper supply and printing difficulties arising from the fuel crisis, it was not possible to produce the catalogue in time for the Exhibition. Consequently, a concise 8-page guide was issued for the convenience of visitors to the Exhibition, followed afterwards by the catalogue itself, a well-illustrated volume of about 380 pages. This catalogue is much more than a guide to the Exhibition: it is, in fact, a work of reference containing descriptions of a very large number of scientific instruments manufactured in Great Britain during recent years.

The Exhibition was a tribute to the high degree of skill and ingenuity shown in the design and manufacture of high-class scientific instruments in Britain. As in previous years, it was divided into two main sections, namely, the Trade Section and the Research and Educational Section. The Trade Section included exhibits from 118 firms of instrument makers, while the Research and Educational Section was represented by twenty-nine organisations, many of these being Government research establishments. During the Exhibition, four discourses were given on recent advances in various aspects of the development of scientific instruments. One of these, given by Dr. Edward Lee (of Admiralty Research Laboratory, Teddington), dealt with the development of certain types of Service infra-red equipment which has in post-war years found valuable applications in research and industry. He dealt in particular with the image-converter tube in which infra-red radiation up to a wave-length of 1·3 μ is transformed into visible radiation. During the discourse the audience were supplied with the Service type of this tube (the R.G. tube) enabling them to see demonstrations of various interesting infra-red phenomena. Dr. Lee referred also to recent progress in the production of lead sulphide photo-conducting cells sensitive up to a wave-length of 3·5 μ. These cells have been used recently in observing transient low-temperature effects which were previously undetectable. He referred to the use of infra-red equipment fitted to military vehicles for driving at night and to the detection of the exhausts of enemy aircraft.

Interesting and instructive discourses were also given on "Recent Advances to Optical Science" and on "Air Photography" by Mr. B. K. Johnson (Imperial College) and by Mr. A. C. Brock (Royal Aircraft Establishment, South Farnborough) respectively. Prof. A. Porter in his discourse dealt with the important subject of "Automatic and Manual Position Control Systems". His remarks were based on various mechanical aspects of fire control and radar systems as used in the Services. He was mainly concerned with a discussion of the relative effects of inertia and damping in follow-up mechanisms, and the introduction of controls including the first and second differentials of displacement.

These discourses are not only of interest to the specialists but have also a more general appeal, and are now one of the important features of the Exhibition. Another feature which is gradually assuming greater importance is the exhibition of scientific and educational films. One of these, of more popular interest, was a 50-min. film depicting episodes in the life of Lord Kelvin. The British Kinematograph Society showed ten films illustrating the uses of motion pictures in scientific research; for example: (1) kine radiograph of normal human joints; (2) super-slow motion of a splash; (3) films in aircraft research, etc. Another film, shown by Kodak, Ltd., Research Laboratories, illustrated the use of the phase-contrast microscope in biological studies.

In a brief review of the Exhibition, it is almost impossible to select even a representative sample of the very numerous exhibits for reference. The following, taken almost at random, may, however, serve as a rough indication of the type of exhibits to be seen. Microscopes, for example, in recent years seem to be departing more widely from the old conventional forms. In the Research Section was shown a reflecting microscope having a numerical aperture of 0·98, with exact focal achromatism, fitted with phase-contrast illumination. Using this instrument, photomicrographs of stained and unstained material (by phase contrast) were shown. Another microscope, of an entirely different type, is the electron microscope. This has now been used in a 'shadow casting' method. Shadow-casts are formed by irradiating a supported specimen obliquely, *in vacuo*, with a stream of gold molecules. Such objects when viewed by transmission in an electron microscope show shadows and gradations of density in a pattern which indicates the detailed shape of the original specimen. A 50 kV. electron microscope, giving total magnifications of the order of 20,000 times, was on view in the Trade Section of the Exhibition. The resolving power of the instrument was stated to be better than 100 A.

Reference has been made to infra-red sensitive cells in Dr. Lee's discourse. The characteristics of lead-sulphide cells as applied to high-speed low-temperature pyrometry were shown in the Research Section. One exhibit demonstrated the quick response-time of the lead sulphide cell, about 20 microsec. at room temperature. At the peak of its sensitivity curve (2·7 μ), it is almost a hundred times as sensitive as the best thermocouple. At liquid-air temperatures its sensitivity is greatly increased, but its response time is now of the order 500 microsec. In addition to its use in spectroscopy, the lead sulphide cell is finding many applications in industrial processes and in research.

Developments in electrical (and electronic) instruments are particularly noteworthy, and more 'Service' applications were released in time for this Exhibition. One form of bomb locator which was exhibited was in principle a very sensitive magnetometer for measuring the distortion of the earth's magnetic field due to the presence of ferro-magnetic material. The sensitive element in this locator is a length of mu-metal wire, the A.C. resistance of which varies with the field along the axis of the wire. Variation of the resistance is indicated by a sensitive bridge circuit. Two widely spaced elements are used to indicate the field gradient.

Perhaps one of the most popular and striking exhibits was the demonstration of centimetre waves and the equipment used in the generation, transmission and reception of centimetre waves. Wave guides, magnetrons, klystrons, dielectric rod and tube aerials, lens-corrected horns, crystal receivers, concentric probes, bolometers for power measurement, polarization-plane changers, etc., for use in micro-wave communications and research were to be seen on several stands both in the Trade and Research Sections. Demonstrations were given illustrating the properties of centimetre waves such as reflexion, focusing, stationary waves, polarization and attenuation.

In the Trade Section a cathode ray tube known as the 'Skiatron' was demonstrated. In this tube the electrons, instead of causing fluorescence when they strike the screen, produce an image of varying opacity which can be projected on a screen, using conventional sources of high-intensity illumination, instead of relying on the relatively weak illumination produced on a fluorescent screen.

Another interesting exhibit in the Trade Section was the equipment used in picture telegraphy. This equipment was designed primarily for use by the Press for the transmission of news-pictures directly over existing telephone networks, or in conjunction with radio links. The commercial applications are obvious, and the system offers possibilities in crime detection, since it permits of rapid transmission of finger-prints and other pictorial matter. The definition obtained in this system is very good, and the speed of scanning satisfactory; for example, a picture 10 in. × 8 in. can be transmitted in 7–20 min., according to the scanning-line and drum speed combination.

An entirely novel feature in this year's Exhibition was the exhibit of the Atomic Energy Research Establishment (Electronics Group). Electronic β-ray counters and health monitors for β- and γ- and slow neutron radiations were demonstrated. Much interest is being taken in the design of Geiger counters and in various forms of apparatus for measuring ionization, with associated electronic equipment. Counting rates as high as 5,000 a minute are now readily obtainable—this compares very favourably with the normal rates of 20–30 a minute when counting α-particle scintil- ations by eye. The importance of the exhibit was not so much in what it actually showed as in what it foreshadowed.

In acoustics, improved types of noise meters were exhibited, and a demonstration was given of the absolute pressure calibration of a microphone by measurement of the amplitude of smoke particles. A novel application of soap films was demonstrated in gas analysis apparatus embodying a dynamic method instead of the more usual static method. The apparatus consists of eight soap film meters incorporating the necessary absorbent solutions. To arry out an analysis, which can be completed in hree minutes, soap films are formed in each meter by raising and lowering valves.

The use of silicone-insulated windings in electric motors running at abnormally high temperatures was demonstrated in another research exhibit.

It is hoped that the above examples sufficiently illustrate the wide range covered by the exhibits. It is practically impossible for the normal visitor, who has only one day to spare to visit the Exhibition, to see everything. All he can do is to take a particular interest in a few items and a more general interest in some of the others—if time permits between his chance meetings with old acquaintances!

The thirty-first Exhibition was, if possible, even better than its predecessors, and the exhibition committee and officers of the Physical Society are again to be congratulated most heartily in the well-merited success of their annual effort.

ACTION OF MUSTARD GAS (ββ'-DICHLORODIETHYLSULPHIDE) ON NUCLEOPROTEINS

By Dr. I. BERENBLUM
AND
Dr. R. SCHOENTAL

Oxford University Research Centre of the British Empire Cancer Campaign, Sir William Dunn School of Pathology, University of Oxford

EARLY studies on the reactivity of mustard gas (ββ'-dichlorodiethylsulphide) with amines and amino-acids[1,2,3] provided the first indication that its vesicant action might depend on a combination with protein constituents of the living cell. Additional indirect support for such a view was the observation that respiratory and glycolytic processes of bacteria[4] and of minced tumour tissue[5] were inhibited by mustard gas *in vitro*, and that with the sulphone analogue there was inhibition of metabolism of brain tissue *in vitro*, representing a selective effect on the pyruvate oxidase system[6]. Actual evidence that mustard gas could combine with proteins became available when serum proteins were shown to acquire new antigenic properties after treatment in the cold with mustard gas[7].

The antigenic change in serum proteins seemed too feeble, however, to account for the striking biological effects of mustard gas *in vivo*. It seemed desirable, therefore, to repeat the work, using skin proteins instead of serum proteins as test material. Preliminary experiments of this kind yielded, however, unexpected results.

A crude aqueous extract of rabbit skin, when shaken with mustard gas, developed a bulky protein precipitate, having a high sulphur content (thus indicating a combination of the protein with the mustard gas), and a high phosphorus content (suggesting that it was nucleoprotein in type). When a more purified preparation of nucleoprotein, derived from calf thymus, gave similar precipitation with mustard gas, while a number of other proteins failed to give this reaction, the originally planned (immunological) work was set aside, and the precipitation phenomenon investigated in greater detail.

Preparation of extracts: Finely minced tissue (skin or thymus) was extracted first with distilled water, and then with several lots of dilute borate buffer at *p*H 8·5. After removal of insoluble matter by centrifuging, the pooled solutions were brought to *p*H 6·0 with dilute acetic acid, and the resulting precipitate separated by centrifuging, and dissolved in 0·05 N ammonia. This was filtered repeatedly through the same filter paper until clear. (This filtration, which lasted several days, was carried out at 3° C.) The clear filtrate was desiccated by lyophilic drying, and the powder extracted in a Soxhlet apparatus with light petroleum (b.p. below 40° C.). Other methods of extraction yielded preparations which reacted essentially in the same way when treated with mustard gas, and need not, therefore, be described here in detail.

The powder was readily soluble in alkaline solutions at and above *p*H 7·5. On acidification to below *p*H 6·5, a precipitate was formed, which dissolved again on re-addition of alkali. An analysis of the powder gave the following values: 12·2 per cent N; 0·89 per cent P; and 1·1 per cent S. (The nitrogen content of nucleoproteins is usually given as about 16 per cent. The somewhat lower value given above is attributable to a relatively high ash content of the test sample.)

Treatment with mustard gas: In the standard test, 0·5–1·0 per cent of nucleoprotein preparation in $M/20$–$M/4$ borate buffer at *p*H 9·0 was continuously shaken with 1 per cent mustard gas per volume of solution, at 37° C. The *p*H of the mixture was adjusted every few minutes, with small additions of dilute sodium hydroxide (using an external indicator), to neutralize the hydrochloric acid liberated from hydrolysis of mustard gas.

Precipitation occurred whether crude or purified preparations were used, or whether these were derived from rabbit skin or calf thymus. (For negative results in concentrated phosphate buffer, see below.) The precipitation began within 2–5 minutes, becoming first noticeable as a turbidity which failed to clear on further addition of alkali.

Influence of *p*H*:* Maximum precipitation occurred in borate buffer at *p*H 8·5–9·0, falling off considerably at *p*H 9·5, and no longer occurring at *p*H 10·0. In phosphate buffer between *p*H 8·0 and 9·0, only slight precipitation occurred. In acetate buffer, from *p*H 6·5 downwards, the normal precipitation (due to acid *p*H itself) became converted into an irreversible precipitation, after shaking with mustard gas (that is, the precipitate failed to re-dissolve on addition of alkali).

The poor precipitation in phosphate buffer was traced to the relatively high competition factor[8] of phosphate ions for mustard gas in the reaction mixture. (This possible mechanism was suggested to us by Mr. J. St. L. Philpot.) Thus, more precipitate developed with mustard gas in a mixture of borate and acetate buffer at *p*H 8·2 than in phosphate buffer at the same hydrogen ion concentration, while no precipitate developed when the concentration of the phosphate buffer was raised to three molar.

Variation in the concentration of reagents: By varying the concentration of nucleoprotein in the test mixture, corresponding differences were obtained in the yield of precipitate, from a bulky precipitate with 1·5 per cent to a mere trace of turbidity with 0·001 per cent. Diminution in precipitation with decreasing amounts of mustard gas (acting on 1 per cent nucleoprotein) followed a more rapid course, from bulky precipitate with 1 per cent mustard gas to turbidity with 0·05 per cent. This was accounted for by the large proportion of mustard gas becoming hydrolysed before being able to act on the nucleoprotein.

Acid effect in mustard gas precipitation: Though the precipitate produced by acid is reversible (that is, it redissolves on addition of alkali) whereas that produced by mustard gas is irreversible, it seemed possible that during the hydrolysis of mustard gas, the acid *produced at the actual point of liberation* might be sufficiently concentrated to cause denaturing of the nucleoprotein. This was excluded by the following tests:

1. Mustard gas and nucleoprotein tested in strongly buffered solution, with frequent adjustments of *p*H and vigorous shaking, so that the maximum fall in *p*H was never more than 0·5: precipitation occurred as usual.

2. Small amounts of concentrated hydrochloric acid, instead of mustard gas, added to a buffered nucleoprotein solution: no irreversible precipitation.

3. Other compounds, known to liberate hydrochloric acid through hydrolysis (see below), tested on nucleoprotein solutions: of these, lewisite, dichlorodimethylsulphide, and *t*-butyl chloride, failed to produce irreversible precipitation.

4. Estimation of sulphur content of nucleoprotein before and after treatment with mustard gas (uncombined mustard gas being removed by extraction of the precipitate with lipoid solvents): sulphur content of acid-precipitated nucleoprotein ranged from 1·1 to 1·7 per cent; sulphur content of treated nucleoprotein with mustard gas ranged from 1·8 to 3·3 per cent, the higher figures being obtained in tests with prolonged treatment with large excess of mustard gas.

Effect of mustard gas on other proteins: Similar tests to the above were made on serum globulin, serum albumin, fibrinogen, prothrombin, hæmoglobin, gelatine, pepsin, and ribonuclease. In the standard tests (lasting 20 minutes) no precipitates developed (except with hæmoglobin, which was accounted for by non-specific precipitation resulting from prolonged shaking).

The tests were repeated for longer periods, with the mustard gas added in divided doses (1 drop to 30 ml. of test mixture every 15–20 minutes) and the amounts of precipitate estimated nephelometrically in a 'Spekker' photo-electric absorptiometer: no effect was observed with ribonuclease; slight turbidity only with pepsin, gelatine, albumin, prothrombin and fibrinogen (the last-mentioned being non-specific, due to shaking); progressively increasing precipitation with globulin, though very much more slowly than with nucleoprotein.

Nucleoprotein precipitation in vivo: If the nucleoprotein inside the living cell became irreversibly denatured following mustard gas application, the amount of soluble nucleoprotein extractable from such tissue should be greatly reduced. This was investigated.

Some neat mustard gas was applied to a large area of skin on rabbits, and two hours later (by which time erythema and œdema were well pronounced), the treated skin, as well as neighbouring normal skin for control, were excised and extracted by the method described above: no detectable nucleoprotein was obtained from the treated skin, whereas the normal skin yielded abundant quantities. When tested at shorter intervals (½–1 hour) after application, some nucleoprotein was extractable from the treated skin—though in greatly diminished amounts compared with the normal skin.

At the suggestion of Dr. R. H. S. Thompson, these tests were repeated on rat skin, using much smaller quantities of mustard gas (for example, 1 drop of a 5 per cent solution in ethanol, an amount known to be just sufficient to produce œdema, and to interfere with enzymic activity of the skin): under these conditions, apparently normal yields of nucleoprotein were obtained from the treated skin (any precipitation that may have occurred being too small to be detected by the semi-quantitative method of comparison used).

Effect of other compounds on nucleoprotein : This investigation, forming part of a separate study, gave results of interest in connexion with the present work, and may be summarized as follows : similar precipitation of nucleoprotein was obtained with a few compounds closely related chemically to mustard gas, all possessing strong vesicant action. On the other hand, lewisite gave no precipitation. In the case of ββ'-dichlorodiethylsulphone and of divinylsulphone, no actual precipitation occurred, but the precipitate formed on acidification (subsequent to the treatment with these compounds) failed to re-dissolve on addition of alkali. (These last results need confirmation on other samples of nucleoprotein.)

Dichlorodimethylsulphide (an analogue of mustard gas, almost non-vesicant, but hydrolysing rapidly in water), also *t*-butyl chloride, and other related compounds, produced no precipitate when shaken with nucleoproteins.

Though conclusions from *in vitro* tests with purified proteins must be accepted with caution, since the 'purification' may have contributed towards the effects produced, the observation that nucleoproteins are rapidly precipitated by mustard gas is rendered significant by the fact that after treatment of skin with mustard gas *in vivo*, no soluble nucleoprotein is any longer extractable. The formation of an insoluble nucleoprotein-mustard gas compound cannot, therefore, be attributed to the use of partially denatured nucleoprotein, but represents a product of interaction which bears some relation to the action of mustard gas on living cells.

As evidence that mustard gas can combine with proteins, these findings support the previous results from immunological studies[7], and are in keeping with he more recent results with corneal collagen[9], keratein[10], various proteins, using mustard gas with adioactive sulphur as tracer[11], egg albumin, casein, and amino-acids[12]. (Reference should also be made o the observed interaction between 'nitrogen mustards' and sodium thymonucleate, etc.[13])

However, unlike the compounds formed by mustard gas with other proteins, that formed with nucleoprotein is highly insoluble. Such specific precipitation *n vivo* may produce special effects, for in failing to precipitate cytoplasmic proteins, mustard gas might be able to penetrate the nucleus and produce characteristic changes there. In this connexion, it may be noted (*a*) that the lethal effect of mustard gas on cells delayed for several hours, as with X-rays, but nlike most other irritants, and (*b*) that mustard gas lso behaves like X-rays in producing mutations in *Drosophila melanogaster*, while other irritants (includng lewisite) do not[14].

Intra-nuclear precipitation of nucleoproteins could nly represent one aspect of the biological action of mustard gas. Apart from the cytoplasmic nucleoroteins, associated with mitochondria, microsomes, tc., there are enzymes of nucleoprotein type (for example, the flavoproteins) in the cytoplasm, precipitation of which would seriously interfere with function. Furthermore, combination of proteins (or other important cell constituents) with mustard gas, *without precipitation*, would also lead to important changes in living cells.

Recent evidence points to a multiple mechanism of vesicant action, and the present results lend further support to this view. Some of the local effects are more likely to be associated with interference with enzyme action in the cell[15], while the hypersensitivity which may develop after repeated exposure is more readily explained on the development of antigenically changed proteins[7]. Nevertheless, in view of the important role which nucleoproteins have in the living cell, their irreversible precipitation *in vivo* is likely to have serious consequences, and may well be largely responsible for the necrotizing effects in mustard gas burns.

This work was carried out in 1940 as part of a programme of extramural research for the Ministry of Supply, and communicated to the Ministry in 1940. We wish to thank Prof. R. A. Peters and other members of the group working in this field in Oxford, for helpful advice, and the Director of Scientific Research (Defence), the Ministry of Supply, for permission to publish these results.

STRUCTURE AND PROPERTIES OF DIAMOND

THE diamond offers a variety of fascinating problems to the research worker interested in the correlation of physical properties with crystal structure, and the well-known variations of crystalline habit, colour, fluorescence, and so forth, are responsible for a bulky scientific literature. Its scientific interest and its beauty as a gem inspired many abortive attempts at synthesis, and probably one successful solution of the problem[1]. It is not surprising that the diamond was among the very first crystals examined by X-ray methods, and the essential simplicity of the structure is in striking contrast with the complexity revealed by a detailed examination of the crystalline form and properties.

The researches of Robertson, Fox, and Martin, published in 1934[2], established firmly the existence of two kinds of diamond, known as Type I and Type II for lack of clear understanding of the origin of the observed differences in various physical properties. Since that time, much experimental data has been obtained by X-ray methods in the Davy

Faraday Laboratory, London, and it is now at least possible to show in what respects the X-ray diffraction effects characteristic of diamonds of Types I and II are *not* explicable in terms of theories which cover phenomena observed with other crystals. A very large amount of interesting experimental work has also been reported in publications from the Indian Institute of Science at Bangalore, especially in two symposia[3,4] on the "Structure and Properties of Diamond". The team at Bangalore, under the direction of Sir C. V. Raman, originally directed attention to anomalies in X-ray scattering, and has more recently applied a variety of physical methods to the examination of a very fine collection of diamonds. The earlier work (particularly that on diffuse X-ray reflexions) served as the basis for the development, by Raman[5], of a general theory of the dynamics of the crystal lattice which has been strongly criticized by theoretical and experimental workers[6] and has not found acceptance in other laboratories than that at Bangalore. Later, in order to provide a structural interpretation of experimentally observed variations in physical properties and growth habit, Raman[3] advanced a theory of the symmetry of diamond which implies the existence of four different crystal structures. Raman's exposition and development of this theory were much less obscure than in the case of the general theory of the crystal lattice, but its application to X-ray diffraction effects has been criticized very severely[7], and again it must be admitted that acceptance is withheld, outside the Bangalore laboratory.

It is against this background that the second symposium on the structure and properties of diamond[4], here under review, must be judged. The style and general content of the twenty-one papers, all contributed by Raman and his collaborators in the Bangalore Institute, show no serious departure from those of previous publications from this school of research; the treatment is in many cases descriptive rather than analytic, and, in the reviewer's opinion, the value of the observational data is reduced rather than enhanced by the insistence with which they are adduced in support of the Raman theories, and stated to be in flat opposition to others. This treatment succeeds only in conveying the impression, whether rightly or wrongly, that the Raman theories dominate the experimental researches of the Bangalore school to an extent which must encourage an uncritical acceptance of interpretations favouring Raman's views, while adverse criticisms of the Raman theories, expressed by other workers in this field of research, remain unrefuted. In the review which follows, therefore, no attempt is made to assess the theoretical significance of the new experimental data.

Crystalline Form and Microscopic Structure

In the first of four papers on topics which may be grouped under this heading, Raman and Ramaseshan (pp. 1–24) develop the idea that the curved faces and edges which frequently occur in natural diamonds are not accidental features of growth, as is commonly supposed, but represent essential properties of the crystal. On this view the curved faces appear as a direct consequence of the act of solidification from a drop of liquid carbon, while the edge-development gives the clue to the true internal symmetry of the structure; the majority of the seventy-two diamonds examined are classified, in this way, as showing tetrahedral symmetry, though truly octahedral symmetry is established in some cases and interpenetration of positive and negative tetrahedral forms is frequent. A semi-quantitative elaboration, by Ramaseshan (pp. 122–129), of the suggestion that curvature of the faces corresponds directly with curvature of the liquid drop of carbon, requires the *ad hoc* assumption that a high degree of directed valency-bonding exists before solidification. The calculations of crystal surface energies are correlated with cleavages in another paper by Ramaseshan (pp. 114–121); but it is perhaps not unreasonable to suggest that these calculations, and the deductions drawn from them, may represent an over-simplification of the very complex energy problems associated with crystal growth and face-development under conditions and in an environment of which little or nothing is known. For their bearing on these views as to the significance of curved faces and edges, the recent experimental observations of Tolansky and Wilcock[8] are of great interest; it seems that the multiple-beam interference technique establishes beyond any reasonable doubt that these features of the topography of the diamond are due to the deposition of a succession of stepped growth-sheets—a mode of crystal growth commonly observed in other substances.

A paper by Ramachandran (pp. 65–80) describes in detail the dimensions, orientation, and optical characteristics of the laminated structures seen under optimum conditions in many diamonds of Types I and II, and attributes the positive and negative uniaxial characters of the laminæ to states of compression and tension arising from variations in lattice-spacing in the different kinds of diamond structure postulated by the Raman theory. The rea existence of such variations in spacing, reported by R. S. Krishnan[3], has, however, been denied by Lonsdale[7], so that the validity of Ramachandran's interpretation of his observations is open to question.

X-Ray Studies

Studies by R. S. Krishnan (pp. 33–44) and by Ramachandran (pp. 95–103) represent the extensio and refinement of researches already reported, th former on the temperature-variation of lattice parameter, the latter on X-ray topography, with a attempt to correlate variations in X-ray reflectin power with the laminations observed optically an with luminescence phenomena.

In a theoretical study, Ramachandran (pp. 58–64 calculates the X-ray diffraction effects to be expecte for a diamond structure in which carbon atom occupy the sites 000, $\frac{1}{4}\frac{1}{4}\frac{1}{4}$ in the cubic unit cell, bu are assumed to have non-spherically symmetrica electronic configurations. He concludes that it i impossible from the presence or absence of the (20 and (222) reflexions to decide uniquely whether th symmetry of the crystal is tetrahedral or octahedra He states, however, that "the (222) reflection is . . absent only in the fully antisymmetric case", whic (if the reviewer has understood Ramachandran nomenclature correctly) is equivalent to saying tha the (222) reflexion is absent only when the two carbo atoms at 000, $\frac{1}{4}\frac{1}{4}\frac{1}{4}$ are identical and have identic orientations, a requirement of the tetrahedr structure. Lonsdale[7] has shown that a real (22 reflexion exists, which would appear, on Ramacha dran's own calculations, to prove that the symmet is octahedral.

Atomic and Electronic Vibrations

The greater part of the symposium is devoted to the observation of optical properties and their interpretation in terms of atomic and electronic vibrations.

Precision measurements are included in six papers, of which two by Krishnan (R. S.) (pp. 25–32 and 45–57) report observations of the second-order Raman spectrum and its variation over a wide range of temperature. Ten distinct second-order lines have frequencies corresponding with infra-red absorption maxima, and five of them are octaves of the frequencies assigned in the Raman theory to lattice vibrations. It is difficult to attach any real significance to the proposed interpretation of the Raman spectra, when Krishnan persists in associating the octave of the fundamental Raman frequency 1332 cm.$^{-1}$ with the steepest point in the curved line joining an infra-red absorption maximum with the adjacent minimum —an arbitrary proceeding already condemned by Sutherland[9]. On the purely experimental side, however, it is to be noted that a recent communication in *Nature*[10] by Krishnan reports the complete resolution of the Raman lines, which in the symposium appear only as minute 'steps' on a continuous faint background.

Four papers by Ramanathan (pp. 130–161) describe infra-red, visible, and ultra-violet absorption properties of a large number of diamonds, and demonstrate that it is not possible to draw a definite line of demarcation between Type I and Type II diamonds from observations on infra-red absorption near 8 μ and ultra-violet absorption near 2250 A.

Descriptive accounts of the luminescence exhibited by diamonds under various stimuli occupy no fewer than five papers, and Ramachandran (pp. 81–94) outlines a semi-quantitative theory of the luminescence due to X-ray excitation. In a short review it is possible to do no more than indicate some of the effects described and discussed in papers by Rendall (pp. 168–175), Chandrasekharan (pp. 182–197), Ramachandran and Chandrasekharan (pp. 176–181); they include the blue and yellow fluorescence patterns, phosphorescence which persists for a short time after cutting off the exciting radiation, thermoluminescence observed on heating to 270° C., and the deactivation effect of radiation of wave-length longer than 4200 A., which causes a 'flash' emission of visible light. In the last of the papers listed above, Ramachandran and Chandrasekharan bring some evidence in support of their suggestion that luminescence effects are due to 'forbidden' electronic transitions.

Conclusion

The symposium includes also papers by Ramaseshan (pp. 104–113) on the Faraday effect and by Achyuthan (pp. 162–167) on photoconductivity, both largely experimental.

Many of the experimental data recorded in this substantial volume of about 200 pages, illustrated by many plates and drawings, are of great interest, actual or potential. The attempted interpretation of these data, however, in terms of the Raman theories, cannot be convincing unless the criticisms already made by workers outside the Bangalore Institute are answered in full and in such a way as to satisfy the critics. Instead, the Bangalore workers would sometimes seem to turn to fresh experimental approaches in the search for further support for their theories, leaving the original criticisms unanswered. The inevitable result is that full recognition is withheld from what is obviously an enthusiastic and hard-working research team, engaged on a problem of great interest and importance.

OBITUARIES

Sir Almroth Wright, K.B.E., C.B., F.R.S.

ALMROTH EDWARD WRIGHT was born in Yorkshire in 1861, the second son of the Rev. C. H. H. Wright, a distinguished Ulster divine, by his wife Ebba, daughter of Nils Almroth, governor of the Swedish Royal Mint. He was educated at first in Germany and France and then privately in Belfast before going up to Trinity College, Dublin, where he graduated B.A. in 1882 and M.B., B.Ch. in 1883, proceeding to the M.D. degree in 1889. After working at the Universities of Leipzig, Strasburg and Marburg, he returned to England to become demonstrator in pathology in the University of Cambridge, where he took the B.A. degree in 1888. In 1889 he became demonstrator in physiology in the University of Sydney, returning three years later to become professor of pathology at the Army Medical School at Netley, where he remained until 1902.

Following up the tentative essays of Pasteur, Haffkine and Pfeiffer, Wright originated in 1896 the system of anti-typhoid inoculation. The results of this prophylactic measure in South Africa and India were so striking that before the outbreak of the First World War it had been made standard practice in the British Army. In 1898 Wright went to India as a member of the Plague Commission. In 1902, following differences with the War Office about anti-typhoid inoculation, he resigned his professorship at Netley and became pathologist to St. Mary's Hospital, London. Here he founded the Inoculation Department, of which he was the first principal. Here, too, he originated the system of therapeutic inoculation for bacterial infections (vaccine therapy) and numerous methods for measuring the protective substances in the blood, notably the opsonic index. He held also a professorship of experimental pathology in the University of London.

In 1914 Wright published the results of his investigations into the incidence, prevention and treatment of pneumonia among the natives employed in the South African mines.

During the First World War, Wright served as consulting physician to the British Forces in France, and devoted himself to studying the immunology of wound infections and to combating the ravages of gas gangrene. This was his last great research.

By 1925, all Wright's important contributions to bacteriology and immunology had been made. He worked as assiduously and devotedly as ever, but in unpropitious circumstances. All the problems susceptible of solution by the methods which Wright had devised and of which he was an acknowledged master had been solved, and the questions awaiting solution could be attacked only by new methods and a new approach. Moreover, the team which he had trained, inspired and led, and which had contributed in no small measure to his triumphs, had disintegrated: some had turned from immunology to other subjects; some had sought greater scope and brighter prospects elsewhere. Other pupils and assistants he had, but times had changed, and they lacked the faith and industry of their predecessors; and, having set their hands to the plough, sooner or later turned back.

In these circumstances, Wright tended to direct his attention more and more to philosophy and, in particular, to logic. The subject had always fascinated him and, as early as 1895, he had contributed to *Brain* a paper "On the Nature of the Physiological Element in Emotion". This contribution he afterwards had reprinted to "demonstrate that some of the problems treated of in this Book have been actively simmering in my mind for at least fifty years". He determined, then, now that opportunity offered, to produce a book of technique for the abstract thinker which should do for him what his book "The Technique of the Teat and the Capillary Glass Tube" had done for the laboratory worker. He felt the inadequacy of formal logic and the sterile ratiocinations of the Schoolmen, of which he says: "And if we were dealing with a syllogism, there would in every case be something which rendered it non-coercive—I am thinking of the fact that we are never in a syllogism given convincing evidence that the major and minor premises can be safely accepted". He proposed to supplement syllogistic induction by a series of criteria of truth, which could be applied to logical propositions as the crucial experiment is applied to physical phenomena. This project, in the course of time, assumed many forms and underwent many vicissitudes, to emerge finally as "Alethetropic Logic, or the Logic which searches for Truth", of which the preliminary volume, "Prolegomena to the Logic which searches for Truth", had appeared in 1941. To this book, which Wright regarded as his *magnum opus*, he was putting the finishing touches: in fact, he was working upon it within a few hours of his death on April 30.

What manner of man was Wright? His intellect, naturally commanding, had, by wide reading, extensive travel and profound reflexion, become a precision instrument of the finest quality. It absorbed and assimilated with equal facility science, literature, law and philosophy, and made him, without apparent effort, a brilliant public speaker and a delightful conversationalist. His place as a pioneer worker and original thinker is assured. But he used his great gifts naturally and without ostentation, so that no one, were he never so young or so unsophisticated, was ever abashed or discomfited in his presence. In controversy, although he loved it, he was not at his best; and gave sometimes a totally erroneous impression of his character and intelligence. On matters of principle he was steadfast and unyielding, but in argument he often appeared elusive and even disingenuous, so that such verbal engagements were usually unsatisfactory and indecisive.

The outstanding trait in Wright's character was his kindliness. No one ever appealed to him in vain for help of any kind, and many were the beneficiaries of his secret munificence. The sight of suffering always affected him profoundly, and this compassion was a spur that ever urged him on. Other endearing traits he had in plenty: great personal charm and an impish sense of humour, unwearying patience and a temper either naturally equable or under complete control, undaunted pertinacity and an equanimity which neither failure nor success could shake.

It is customary, when writing of a great man, to say that we shall never see his like again; but this is literally true of Almroth Wright, for while heredity might play its part in producing his peer, the environment, in which alone so bold, fearless and uncompromising a spirit could flourish and attain full stature, has passed away. R. T. MUMMERY

Prof. Heinrich Kayser, For.Mem.R.S.

WAR conditions led to the fact that the death of Heinrich Kayser on October 14, 1940, at Bonn at the age of eighty-seven passed unnoticed in Great Britain.

Born at Bingen on March 16, 1853, Kayser was educated at the Sophieen Gymnasium in Berlin and at the University of Strassburg under Kundt; there one of his fellow students was Röntgen. He took his doctorate at Berlin and became an assistant to Helmholtz in 1879. He was introduced to spectroscopy in 1880 by Hagen, one of his fellow assistants, and at once became drawn to the subject, publishing his "Lehrbuch der Spektralanalyse" in 1883. In 1885 he was appointed to the Technische Hochschule in Hanover, where he had as his colleague Runge, and as assistant Paschen. The nine years at Hanover, before he succeeded Hertz at Bonn, were very fruitful in tables of the spectra of the different elements, of which the best known was the photographic map and table of wave-lengths for the spectrum of the iron arc from 2500 to 6600 A., published in collaboration with Runge.

The work on which Kayser spent most of his twenty-five years at Bonn—his life-work—was the "Handbuch der Spectroscopie", of which the sixth volume came out in 1912. It was a stupendous undertaking, a compendium of all that was known in spectroscopy. The subject had grown so much while the work was in progress that the proposed volume on astrophysical applications got squeezed out, and two supplementary volumes were needed and brought out with the aid of Konen and others after Kayser had passed the age of eighty. Other valuable contributions in his later years included a "Tabelle der Hauptlinien der Linienspektren aller Elemente"; but the "Handbuch" remains as his monument.

Kayser's wide knowledge of languages was a great help to him in his work and was combined with a passion for travel, in part inherited from his parents. He was one of the founders of the International Solar Union in 1904 and attended its meetings regularly; he was the genial host at Bonn for the meeting in 1913. Though he was one of the first to be co-opted, when that became possible, on to a commission of the International Astronomical Union, that of Standard Wave-lengths, he never attended its meetings. He was elected a foreign member of the Royal Society in 1911 and was present and spoke at the two hundred and fiftieth anniversary gathering in 1912; of this meeting he said in his autobiography, written at the age of eighty-three: "Überall zeigt sich als alteingewurzelt Tradition, Reichtum, Macht; und das wirkt mehr als alle Reden".

F. J. M. STRATTON

Dr. J. D. Falconer

Dr. John Downie Falconer, geologist and geographer, died at Hounslow on April 16. The news of his death came as a shock to his friends, since he was present, and in apparent good health, at the annual meeting of the Geological Society just a month before.

Falconer was born in Midlothian in 1876 and was educated at the Universities of Glasgow and Edinburgh. During 1901–4 he was assistant to Prof. James Geikie, and he then went to Northern Nigeria as principal of the Imperial Institute Mineral Survey, returning to the University of Glasgow to take up the appointment of lecturer in geography in 1911. He went back to Northern Nigeria in 1916 as an assistant district officer, but in 1918 he was made director of Geological Survey for Nigeria, a post he held until 1927. During 1928–34 he was geologist to the Republic of Uruguay.

Dr. Falconer was the author of many papers and official bulletins, and of works in lighter vein on his travels in Nigeria and Uruguay. In 1937 he published a book on Darwin in Uruguay. The work for which he is best known and will long be remembered with appreciation is that relating to the physiography, geology and mineral resources of Nigeria, the results of which are in part incorporated in his "Geology and Geography of Northern Nigeria". This book and the accompanying map remain a valuable source of information, and the theoretical discussions, while not always in accord with modern views, have served as a great stimulus to further investigation. His work was characterized by thoroughness and wide knowledge of his subject, and it stands as a tradition and an inspiration to the Geological Survey of Nigeria, of which he was the first director. He was responsible for the earlier issues of the bulletins of the Geological Survey of Nigeria and the accompanying geological maps, which were of considerable scientific and economic value, especially as regards the tin resources of Nigeria.

The Geological Society awarded Dr. Falconer the Lyell Fund in 1920, and he served on the Council of the Society during the period 1927–29.

His loss is deeply felt by many friends and former colleagues, and by the mining community of Nigeria.

F. Dixey

Prof. Fritz Weigert

The death of Prof. Fritz Weigert on April 13 was a loss to science, and came as a sad blow to a wide circle of friends and colleagues who admired him as much for his personal charm and wide culture as they respected him for his academic achievements.

Fritz Weigert was born in Berlin in 1876, where he received his education as a chemist. While his early collaboration with such men as van't Hoff and Nernst in Berlin and Robert Luther in Leipzig no doubt had a profound influence on his life-work, the originality and highly individual character of his subsequent researches in photochemistry and related fields must be attributed to his own peculiar gifts, both in the brilliant improvisations of technique and in his imaginative approach in the interpretation of results and formulation of new theories.

In 1914 he was appointed professor of photochemistry at Leipzig, in succession to Luther, and in his inaugural lecture he put forward the courageous, if unorthodox, suggestion that in a new field of research (as the study of photochemical reactions then was), rigid systems of interpretation, even if afterwards proved to be wrong, are justified on the grounds that new experimental methods may thereby be disclosed and new angles of approach discovered, which would be a stimulus for further research. In Weigert's hands, this double-edged weapon undoubtedly bore rich rewards in his researches, though it may also have been in part responsible for the tardiness in acknowledging all the credit due to him.

After thirty years of research in physical chemistry in Germany, Fritz Weigert had, with the advent of Nazism, to seek refuge in a foreign land; and so began his second career, at the age of sixty, as director of the Physico-chemical Department of the Cancer Research Institute, Mount Vernon Hospital, at Northwood, Middlesex. It is hard to say whether the choice of cancer research was entirely dictated by circumstances, or whether it was not partly influenced by his heritage, for he was the nephew of two of the most distinguished pathologists of the last century—Paul Ehrlich and C. Weigert.

The study of the metabolism of the carcinogenic hydrocarbon, 3 : 4-benzpyrene, by the application of fluorescence spectrography, which Weigert undertook in his new position, was ideally suited for a man of his ability, and he threw himself into the problem with the energy and enthusiasm that a man half his age might have envied. His contributions to this field were significant and stimulating, and characteristic of the man, both in the sphere of technique (as in his adaptation of fluorescence spectrography for the study of hydrocarbons adsorbed on alumina columns) and in the realm of interpretation of results.

Fritz Weigert was, to the end, a keen and active worker, and, despite his deafness, a witty and lively conversationalist. His death was unexpectedly sudden, as he himself would no doubt have wished it to be.

I. Berenblum
H. von Halban

Alice Lady Avebury

The death of Alice Lady Avebury at High Elms, Downe, Kent, on March 11, at the age of eighty-five, removed an important link between the two leading prehistorians of the Victorian period. She was the daughter of General Pitt-Rivers and the wife of the first Lord Avebury. From her father she inherited much—his clear intellect, his orderly ways and his imperious manner. She was Lord Avebury's second wife, being married to him in 1884 while he was still Sir John Lubbock, member of Parliament, banker, author of "Prehistoric Times" and the father of Bank-Holidays. The Lubbock home, at High Elms, was a centre where the celebrated men of science of the Victorian period came to spend week-ends. Lady Avebury was an ideal hostess, and around her many new friendships were formed. She was a woman of wit and of beauty, never afraid to give utterance to what she really thought and believed. She was on the most friendly terms with the Darwin family at Down House, and when Darwin's home passed into the custody of the British Association she continued her association with that remarkable place. She welcomed the transfer of the historic Lubbock home of High Elms with its park and woods to London's Green Belt; indeed, she took the initiative in this transfer. Her daughter, the Hon. Mrs. Ursula Grant Duff, continues the Avebury interest in social science.

Arthur Keith

NEWS and VIEWS

Prof. Carl Størmer

On May 20 the University of Oxford conferred the degree of D.Sc., *honoris causa*, upon Prof. Carl Størmer, who later on the same day delivered the Halley Lecture on "Polar Aurora in Southern Norway". The presentation speech by the Public Orator at the degree ceremony was in Latin elegiac verse, with a prose addendum which included the remark that Prof. Størmer richly deserved a gown equally worthy of the Goddess of Dawn and the Goddess of Learning. The verse described an imaginary interview between the Public Orator and the Goddess Aurora, who was visible (so it seemed) in the northern skies at night during the recent hard weather, and appeared to have deserted her usual haunts and her husband Tithonus. Aurora bade the Orator to improve his knowledge of celestial phenomena (and his opinion of her) by consulting the eminent Norwegian astrophysicist Prof. Størmer, whose pride it was to have mastered the nature of her counterfeit, the Aurora Polaris, determining the situation, form, motion and spectrum of this phenomenon. He could also speak with authority on the 'mother of pearl' clouds high in the stratosphere, and in addition had long studied the motion of charged particles arriving at the earth from the sun.

Prof. Størmer, now emeritus professor of pure mathematics at the University of Oslo, besides making distinguished contributions to that subject, and applying it to the study of the motion of charged particles in the earth's magnetic field, thus explaining many remarkable observed characteristics of the Aurora Polaris, has for more than a third of a century been the foremost leader and organiser of auroral observation by simultaneous photography from two or more well separated stations in Norway. This work has brought a rich harvest of increased knowledge of the Aurora Polaris, presenting a fascinating set of problems for theoretical geophysicists. As by-products of his observing organisation, Prof. Størmer has also made important additions to our knowledge of 'mother of pearl' clouds and of winds in the upper atmosphere, as indicated both by such clouds and by meteor trails.

British Rubber Producers' Research Association: Dr. Geoffrey Gee

Dr. Geoffrey Gee, who has recently been appointed director of the British Rubber Producers' Research Association's extensive laboratories at Welwyn, has made important contributions to our knowledge and understanding of the properties of long-chain polymers, especially rubber. His early work at Cambridge dealt with the kinetics of polymerization reactions both in bulk and at interfaces. More recently, he has undertaken a critical examination of the thermodynamics and statistical mechanics of systems involving rubber and related polymers. The last decade has witnessed striking advances in the mathematical treatment of the behaviour of long-chain molecules, but there has been a dearth of exact experimental data, thus precluding any development of the statistical mechanical treatment. Dr. Gee with his collaborators has been able to provide reliable and extensive experimental data which have permitted them in turn to make advances in the theoretical treatment. The determination of the molecular weights of rubbers and the inter-relationship of the different methods; the connexion between the heats of mixing of rubber and liquids and their cohesive energy densities constitute two of the more important sections of his work.

Sir Edwin Ray Lankester (1847–1929)

The greatest morphologist of his generation, Sir Edwin Ray Lankester was born a century ago, on May 15, 1847. He was the son of a medical man, he taught medical students, and throughout his career delighted in making zoology serve medicine. When he graduated at Oxford in 1870, biology was still regarded as an apanage of medicine. Those desirous of devoting their lives to the pursuit of comparative anatomy, zoology or physiology had to seek a post at a medical school. It was Huxley who urged budding biologists to seek out independent paths for themselves. In 1874, Ray Lankester, then aged twenty-seven, was appointed to the Jodrell chair of zoology at University College, London. In 1891 he became Linacre professor of comparative anatomy at Oxford, returning to London two years later to succeed Sir William Flower as director of the British Museum (Natural History). On his retirement at the age of sixty he was created K.C.B. A tireless worker and a prolific writer, Ray Lankester's individual contributions to zoology were numerous and distinguished; yet he was at home in almost all fields of biological knowledge. A massive yet nimble mind dwelt in a massive frame. Impatient, utterly fearless, sociable, charming, with a deep booming voice, Ray Lankester was one of the most brilliant and imaginative lecturers in British science. He died on August 15, 1929.

Linnean Society of London: Anniversary Meeting

At the anniversary meeting of the Linnean Society of London held on May 24, the president, Prof. G. R. de Beer, announced that a message of congratulation had been addressed to H.M. Queen Mary, honorary member of the Society, on the occasion of her eightieth birthday, and that H.R.H. the Princess Elizabeth had been pleased to accept the honorary membership of the Society. He delivered a presidential address on "How Animals Hold Their Heads". The Linnean Gold Medal was awarded to Prof. Maurice Caullery, of Paris, who was present to receive it. The following were elected officers for the session 1947–48: *President*, Prof. G. R. de Beer; *Treasurer*, Colonel F. C. Stern; *Secretaries*, Dr. Malcolm A. Smith (Zoology) and Dr. B. Barnes (Botany). The new Members of Council were Prof. G. D. Hale Carpenter, Mrs. Vera Higgins, Mr. E. W. Mason, Dr. W. E. Swinton and Dr. George Taylor. The following were elected foreign members: Prof. A. Chevalier, Muséum d'Histoire Naturelle, Paris; Prof. C. M. Child, University of Chicago; Prof. E. Fischer-Piette, Laboratoire de Malacologie, Paris; Prof. E. Hultén, Natural History Museum, Stockholm; Dr. G. G. Simpson, American Museum of Natural History, New York. In addition, W. G. Mackenzie, curator of the Chelsea Physic Garden, and A. W. Stelfox, of the National Museum of Ireland, were elected associates *honoris causa* of the Society. During the proceedings a film entitled "The Development of the Sperm Cells of the Grasshopper" was shown, with a commentary by Dr. C. D. Darlington.

Scientific Research Organisation in Great Britain

In the first A. D. Little Memorial Lecture, "Science, Industry and Government", now published in *Technology Review* (February 1947), Sir Edward Appleton, speaking before an American audience, reviewed British experience in the organisation of research. Success in the organisation of science in the war effort has led the public to conclude that science should play a similar part in solving the problems of peace. Ultimately the provision of work, homes, food, health and safety from aggression for all depend for solution on the maintenance of the same kind of partnership between government, science and industry which grew up during the War; and, referring to the brilliant team-work during the War, Sir Edward pointed out that the result of the policy pursued was that the research establishments of the Services were strengthened by the addition of many brilliant minds from the universities, while the research teams in industry were left intact and ready to attack, as composite units, the problems allotted to them. One of the most striking results of war-time experience in Britain was the brilliant success of university research workers in solving war problems entirely remote from their peace-time interests. University conditions appear to ensure the maintenance of the mental adventurousness and lively imagination so necessary for scientific progress; and in planning the future of the Scientific Civil Service in Britain, an attempt is being made to secure conditions that encourage these qualities.

The most successful applications of science in our war-time experience resulted from the closest possible collaboration between the men of science and the military staff; the field in which the scientific worker can usefully operate extends far beyond the laboratory. Free fundamental research had, however, been almost entirely in abeyance in Britain, and we must recognize the return of peace by changing our priorities. In many fields, we have been living on our scientific capital, which now stands urgently in need of replenishment. Pointing out that scientific research in the universities is of relatively modern growth, Sir Edward referred to the accepted university tradition that teachers of scientific knowledge should also advance that knowledge. Although carried out in a spirit of pure inquiry, this free fundamental research has shown a surprising capacity for being useful. The universities are also the source of the trained scientific workers for university, government and industrial laboratories, and in this connexion Sir Edward referred to the outstanding importance of the exceptional man. Most of the really great advances in science have been accomplished by small teams of workers led by a man with ideas, and Sir Edward believes that a vital task is to see that such men lack neither disciples, assistants nor equipment.

Magnetic Recording of Sound

A lecture on "Developments in Magnetic Recording" was given by Mr. P. T. Hobson to the British Sound Recording Association on March 27, with demonstrations of the wire-recording machine now in production and available in small quantities for non-entertainment purposes. A model of a high-grade instrument shows that the technique of wire-recording has risen so rapidly in recent years that the quality of reproduction obtained can be classed as high, if not higher, than with the best disks and the Philips-Miller system. The comparative cheapness of the wire, the possibility of erasure and the immediate rewind makes magnetic recording attractive for many purposes, apart from the straight and protracted reproduction of music. Ever since Poulsen discovered the possibility of magnetic recording nearly fifty years ago, designers have been misled by the erroneous idea of the exact process of magnetization. Research by the Armour Corporation of the United States and also in Britain has led to the selection and heat-treatment of the steel wire so that a diameter of only 4 mils and a velocity of 24 in. a second can give high-quality reproduction with a signal-to-noise ratio of some 60 decibels. The material is a stainless steel, heat-treated with a current to bring it into the austenitic condition, and with a maximum ratio of the coercive force to remanence, this being the condition for minimizing the almost complete self-demagnetization of the disk-like magnets of which the wire seems to be comprised at the highest frequencies and shortest wave-lengths with tolerable loss.

Mr. Hobson gave an exposition of the theory of such longitudinal magnetization and explained the great advantage of polarizing the magnetizing current with a large component of high carrier-frequency current, which is also used for erasing. The standard machines use reels for recording for a total of 66 minutes, but sufficient quality is left at lower speeds for a total time of eight hours. The non-entertainment machine can run at various speeds for transmitting or receiving high-speed alternating-current signals, while the proposed music-machine not only uses a capstan on which ordinary disks can be played, but also includes an ingenious mechanism which automatically wraps the wire round the capstan for recording or reproducing from wire, thus making the machine substantially foolproof. If the wire should break, a knot can be tied in it.

Research in the South Pacific Area

An important outcome of the South Seas Conference at Canberra, January 28–February 6, 1947, attended by delegations representing the Governments of Australia, France, the Netherlands, New Zealand, Great Britain and the United States, which administer non-self-governing territories in the South Seas, was the signing of an agreement establishing the South Pacific Commission, which will seek to promote the economic and social welfare and advancement of two million people in the South Pacific. The Commission is to appoint an advisory research council of persons distinguished in fields of research within the competence of the Commission, including some full-time appointments of persons highly qualified in the fields of health and economic and social development, together with a full-time director of research. The functions of the research council include the maintenance of a continuous survey of research needs in the territories within the scope of the Commission, and making recommendations to the Commission on research to be undertaken; arranging for the prosecution of research studies approved by the Commission, using existing institutions where appropriate and feasible; and co-ordinating the research activities of other bodies working within the field of the Commission's activities, and availing itself, where possible, of the assistance of such bodies. The council may also appoint technical standing research committees to consider problems in particular fields of research, and, with the approval of the Commission, *ad hoc* research committees to deal with special problems.

Grading of Scientific Films

A MEMORANDUM on "The Classification, Appraisal and Grading of Scientific Films" issued by the Scientific Film Association, 34 Soho Square, London, W.1, has been drawn up by the Association after consultation and discussion with interested bodies in Britain and in other countries. It is primarily concerned with films of scientific interest for adult audiences; but the method of appraising and grading recommended should be applicable to all types of documentary films. A specimen card on which it is recommended the content and lay-out of the data concerning each film should be standardized is appended, together with a definition of terms commonly used in a special sense by the film industry and film critics. Notes are included on the synopsis of the content of each film, which should be brief and objective, as well as on the determination of accuracy and comprehensiveness within the terms of reference laid down by the producer and with reference to the purpose of the film, while the grading of the film in relation to the types of audience likely to see it is considered separately. The organisation of the viewing panel, the appraisal group meetings, the appraisal standing committee and the records to be kept are dealt with in the next section, which includes a specimen viewers' report form. The Association hopes that the principles suggested here will be applied wherever films are appraised. It has earned the gratitude of scientific workers who may need to use such films, as a step towards a standard procedure for film documentation which, if accepted internationally, would be of immense value to all who make or use educational films.

Journal of Glaciology

THE Association for the Study of Snow and Ice, formed in 1936, has grown into the British Glaciological Society, which this year has started the publication of the *Journal of Glaciology*. There is room for such a publication not only to produce the papers read before the Society itself but also to consider many practical aspects of snow and ice. Without undue overlapping, it is clearly desirable to make contacts with various aspects of geomorphology, meteorology and geography. The *Journal* (price 7*s*. 6*d*.) is under an editorial committee consisting of Messrs. G. Seligman, W. L. S. Fleming, B. Roberts and R. Moss, and its present address is care of the Royal Geographical Society, London, S.W.7. The first number has varied contents following an introductory note by Prof. H. W. Ahlmann. Mr. G. Seligman explains Dr. R. Streiff-Becker's theory of extrusion flow in glaciers, and the Rev. W. L. S. Fleming discusses some of the Antarctic glaciological researches of Byrd's Third Antarctic Expedition. There are also a number of short articles and the first instalment of a list of recent glaciological publications, in the main non-polar works. The *Journal* promises to find a place among scientific periodicals of value.

U.S. Chemical Corps Advisory Committee

AT the request of Major-General Alden H. Waitt, chief of the U.S. Chemical Corps, an advisory committee has been appointed to serve as a liaison group between the Corps and the chemical profession and industry, and to provide advice on scientific and personnel matters in connexion with Chemical Corps research and development. The committee is as follows: Dr. W. Albert Noyes, jun., president of the American Chemical Society and head of the department of chemistry in the University of Rochester (*chairman*); Prof. R. Adams, University of Illinois; Prof. A. C. Cope, Massachusetts Institute of Technology; Colonel Bradley Dewey, of Cambridge, Mass., formerly U.S. Rubber Administrator; Dr. Willard H. Dow, president and chairman of the Dow Chemical Co., Midland, Mich.; Prof. Vincent du Vigneaud, Cornell University Medical College; Prof. Louis F. Fieser, Harvard University; Dr. Per K. Frolich, co-ordinator of research of Merck & Company, Rahway, N.J.; Prof. H. F. Johnstone, University of Illinois; Sidney D. Kirkpatrick, chairman of the American Section of the Society of Chemical Industry; Dr. Walter Kirner, director of the Chemical and Biological Coordination Center of the National Academy of Sciences; Dr. Stanford Moore, Rockefeller Institute for Medical Research; R. L. Murray, vice-president and technical director of the Hooker Electrochemical Co., Niagara Falls, N.Y.; Prof. Charles C. Price, Notre Dame University; Prof. Glenn T. Seaborg, University of California; Prof. Harold C. Weber, Massachusetts Institute of Technology; and Dr. Robert E. Wilson, chairman of the board of directors of the Standard Oil Co. of Indiana.

Chinese Fisheries

AFTER many years of devastation China is now, with the help of the United Nations, endeavouring to bring about the rehabilitation of her basic industries. Not least in importance is the fishing industry, and a Chinese Fisheries Research Institute has been formed for the purpose of carrying out investigations necessary to guide the Chinese fisheries industry during the difficult period of the immediate future and to provide data upon which to base enlightened fisheries administration. Implementation of this programme is severely hampered by lack of books and equipment, and an appeal has been launched for donations of any suitable books, journals and other periodicals that individuals or institutions may be able to spare. As the Institute possesses little more than a measuring-board in the way of equipment, donations of scientific apparatus will also be welcomed. All gifts and offers of help should be sent to the Director, Fisheries Research Institute, Room 402, National City Bank Building, 54 Kiukiang Road, Shanghai, China.

Quality Control Methods in Canada

A SPECIAL committee has just been established by the National Research Council of Canada to promote the application of mathematical methods in the treatment of certain industrial production problems. Members of the committee include specialists in statistical quality control procedures, in sampling surveys, in the design of experiments, and in biometry or the statistical study of variation; the chairman is Dr. J. W. Hopkins, National Research Council, Ottawa. The committee will assist Canadian users of mathematical statistical methods by consultation and advice respecting specific technical problems; it will also support research in this field by qualified workers, and provide a means of liaison with technical groups in Canada and abroad.

International Union of Biological Sciences: Fellowships

APPLICATIONS are invited for the following fellowships: two at the Zoological Station, Naples; one at the Marine Biological Station, Roscoff (France); one at the Central Bureau for the Cultivation of Fungi, Baarn (Netherlands). These fellowships are open to graduate students of biology in its widest sense from universities all over the world. The value of each fellowship will be 750 dollars for students from Europe, and 1,000 dollars for students from outside Europe (travelling and lodging expenses included); duration of stay at least eight months. Applications, giving full information concerning the proposed investigations, must reach the executive committee of the International Union of Biological Sciences, c/o Prof. M. J. Sirks, Genetisch Instituut, Huis de Wolf, Haren (Gron.), Netherlands, before October 1, 1947.

James Hutton Memorial

THE Royal Society of Edinburgh, in conjunction with the Royal Physical Society, the Edinburgh Geological Society, the Geological Society of Glasgow, and H.M. Geological Survey (Scotland), has appointed a committee to organise an appropriate commemoration of the 150th anniversary of the death of James Hutton, "the Father of Modern Geology". Among other items it is proposed to erect a granite panel, suitably inscribed, at the site of Hutton's unmarked grave in Greyfriars Churchyard, Edinburgh. Subscriptions are invited to defray the cost of this memorial. Any sum in excess of the amount required will be applied towards the cost of a publication, which is at present under consideration. Subscriptions, not to exceed *5s.*, should be sent to the Treasurer, Royal Society of Edinburgh, 22 George Street, Edinburgh 2, for the James Hutton Memorial Fund.

The Night Sky in June

FULL moon occurs on June 3d. 19h. 27m., U.T., and new moon on June 18d. 21h. 26m. The following conjunctions with the moon take place: June 2d. 00h., Jupiter 0·02° N.; June 16d. 08h., Mars 0·7° N.; June 17d. 10h., Venus 1° S.; June 20d. 14h., Mercury 4° S.; June 21d. 11h., Saturn 4° S.; June 29d. 01h., Jupiter 0·3° S. Mercury is an evening star, setting at 21h. 43m. on June 1 and at 21h. 06m. on June 30. It attains its greatest eastern elongation on June 17 and is stationary on June 30. Venus is a morning star, rising at 3h., 2h. 44m., and 2h. 41m., at the beginning, middle and end of the month respectively. More than 90 per cent of the disk appears illuminated, and the stellar magnitude of the planet is $-3·3$. Mars rises in the early morning hours but is too close to the sun for favourable observation. Jupiter, in the constellation of Libra, can be seen until the early morning hours, setting at 3h. 06m. on June 1 and at 1h. 05m. on June 30. Saturn is visible in the early portion of the night, setting at 23h. 39m. and 21h. 54m. at the beginning and end of the month, respectively. Occultations of stars brighter than magnitude 6 are as follows: June 6d. 01h. 33·6m., φ Sgtr. (*D.*); June 6d. 02h. 50·8m., φ Sgtr. (*R.*). The latitude of Greenwich is assumed and *D.* and *R.* refer to disappearance and reappearance, respectively. A partial eclipse of the moon, partly visible at Greenwich, occurs on June 3. The moon enters the umbra at 18h. 56·2m. and leaves it at 19h. 34·2m. The eclipse will not be very spectacular, as its magnitude is only 0·024. Summer solstice occurs on June 22d. 06h.

Announcements

THE Very Rev. Alan Campbell Don, dean of Westminster, and Sir Robert Robinson, president of the Royal Society, have been elected honorary members of the Institution of Civil Engineers.

DR. J. H. QUASTEL, director of the Unit of Soil Metabolism of the Agricultural Research Council, has been appointed to the chair of biochemistry at McGill University, Montreal; he will be associate director of the newly created Institute for Special Research and Cell Metabolism and will also take charge of the Enzyme Division of the Institute. He is taking up his new duties on September 1.

WARNER MEMORIAL MEDALS for 1947 of the Textile Institute have been awarded to D. A. Derrett-Smith and Dr. D. A. Clibbens. These Medals were founded in 1930 in memory of the late Sir Frank Warner, formerly president of the Institute, and are given for original investigation published in the *Journal* of the Institute.

DR. HERMAN F. MARK, director of the Institute of Polymer Research and professor of organic chemistry at the Polytechnic Institute of Brooklyn, New York, has been invited to the Chair Francqui at the University of Liège for the academic year 1947–48. The Chair Francqui is a guest professorship involving the delivery of lectures at several Belgian universities for a period of about six months. Previous occupants of the chair have been P. Debye, H. S. Taylor, A. St. Györgyi and Victor Henry.

DR. E. EMMET REID, emeritus professor of chemistry in the Johns Hopkins University, research adviser to several colleges and universities in the southern United States, has been awarded the Herty Medal for outstanding contributions to chemistry in that region. The Herty Medal is given by the Chemistry Club of the Georgia State College for Women on the recommendation of the Georgia Section of the American Chemical Society. The late Dr. Charles H. Herty, after whom the medal is named, and who was president of the Synthetic Organic Chemical Manufacturers Association during 1921–26 and twice president of the American Chemical Society, was born on the site of the College campus.

MR. W. V. D. PIERIS, geneticist, left the service of the Coconut Research Scheme (Ceylon) in September, 1946. The designation of the post has been altered to botanist, and the board of management has appointed thereto Dr. T. S. Raghavan, formerly professor and head of the Department of Botany, Annamalai University, Annamalainagar, South India. Dr. Raghavan's interests have been mainly cytological and cytogenetical. Recently he has synthesized a new species of *Sesamum* by hybridization between *S. orientale* and *S. prostratum*. The sterile hybrid has been made fertile through the induction of amphidiploidy by artificial means. In the hybrid has been incorporated the perennial habit of the *prostratum* parent.

Quantum Theory of Liquids

A SHORT account of a general kinetic theory of liquids which we have recently published in *Nature*[1] ended with the enumeration of a series of problems yet unsolved which were our next aim. The most important of these generalizations is the quantum theory of liquids, because of the strange properties observed in liquid helium II.

An attempt to formulate such a theory has been made by Landau[2], in which he transcribed the hydrodynamical equations into operator equations. The meaning of these is obscure, and Landau makes no application of them apart from the general remark that in quantum liquids there will be 'phonons', which correspond to quantized acoustical waves, and 'rotons', which correspond to quantized vortex motion and will have a set of discrete states like those of the angular momentum in ordinary quantum mechanics. This idea is then used as the basis of some plausibility considerations by means of which he tries to explain some of the characteristic properties of He II. Landau's main result, the existence of two distinct velocities of sound, however, rests on quite different assumptions.

We cannot accept this assortment of unrelated suggestions as a solution of the problem of 'quantum liquids'. The correct approach consists, of course, in a direct application of the laws of quantum mechanics to a dense assembly of particles. There are no new principles involved (just as in our classical kinetic theory of liquids) but only mathematical difficulties to overcome, which are mainly due to the close packing. We found that the proper tool for this purpose is the 'density matrix', introduced by von Neumann[3] and Dirac[4] and studied in detail for equilibria by Husimi[5]. It is a function of two different configurations $X = (X_1, X_2, \ldots X_N)$ and $X' = (X'_1, X'_2, \ldots X'_N)$ of all N particles, $\rho_N(X, X')$, and it replaces the distribution function of co-ordinates X and velocities ξ, $f(X, \xi)$, which is used in classical theory. Its change in time depends on the differential equation

$$\hbar \frac{\partial \rho}{\partial t} = W\rho - \rho W, \qquad (1)$$

where W is the energy operator and the products are matrix products according to the ordinary laws of quantum theory.

We proceed now, just as in the classical theory, by forming a set of distribution functions

$$\rho_1(X_1, X'_1),\ \rho_2(X_1, X_2, X'_1, X'_2),\ \ldots,\ \rho_N(X_1 \ldots X_N, X'_1 \ldots X'_N),$$

where each function is obtained from the following one by taking the trace with respect to one pair of variables. It can be shown that the function $\rho_q(X,X')$ satisfies an equation which differs from (1) only by adding a 'statistical term' quite analogous to that appearing in the classical theory. The diagonal terms of ρ_1 represent the number density $n_1(X_1)$, those of ρ_2 the radial distribution function $n_2(X_1,X_2)$, and it can be shown that just as in the classical theory all thermodynamic properties can be expressed in terms of these two functions.

The hydrodynamical equations (including the equation of continuity and that of energy transport) can then be derived in a straightforward way. Thus we obtain the main result, that the quantum laws governing the behaviour of matter in bulk are identical with the classical laws, in sharp contradiction to Landau's formalistic approach. Quantum theory appears only in the atomistic interpretation of the quantities appearing in the equations. It is in this interpretation where very great deviations from the ordinary behaviour of a 'classical' liquid are found. We enumerate a few of these below.

The dynamical equations contain a temperature T_1, defined by the mean kinetic energy, which is not identical with the equilibrium temperature T, defined as the integrating denominator of the entropy. It is the gradient of T_1 which determines the flux of energy. Hence it must be expected that heat transfer does not depend in the usual way on differences of temperatures T measured by thermometers. This makes the properties of He II at once appear less paradoxical.

In the same way, the pressure p_1, the gradient of which determines the acceleration of mass, is not identical with the thermodynamical pressure p, defined as the negative derivative of the free energy with respect to volume. Hence differences of ordinary pressure will not have the effect expected from the usual theory. Again, the application to He II is obvious.

Concerning the dynamical constants, the coefficients of viscosity and thermal conductivity, it can be shown that they are represented by exactly the same formulæ as in the classical theory. Each consists of two parts, a 'kinetic' one depending on the distortion of the velocity distribution by the flux, and a 'potential' one, depending on the distortion of the radial distribution function n_2. The first part alone appears in ideal gases, but is negligible in liquids. The anomalies in liquid helium are therefore presumably due to the properties of n_2, which for low temperatures are indeed quite different from those in the classical domain. This has been shown by detailed calculations made by one of us (H. S. G.) for the extreme case $T = 0$. At high temperatures the nearest approach of two particles is determined by repulsive forces; as the radial velocity vanishes at this distance, there is a considerable probability of finding particles just above this distance, and none a little below. Near the absolute zero, however, the velocities are small, hence the de Broglie wave-length is large compared with the range of the forces; no scattering takes place, but the velocity is increased by the attractive forces, which reach to greater distances than the repulsive forces. Hence the probability of finding particles at a given distance (which is reciprocal to the velocity) decreases from a larger distance, quite independently of the ordinary collision diameter. All physical properties expressed by integrals over functions which contain n_2 as a factor will therefore show anomalies at very low temperatures. For the case of viscosity these results are in agreement with an interpretation suggested by R. Fürth, which he explains below.

The main problem for a quantitative theory is the explanation of the thermodynamical discontinuity separating normal He I from abnormal He II. For this purpose the temperature-dependence of n_2 has to be studied; investigations of this question are in progress (H. S. G.). This function n_2 is also obtainable by experiments with X-rays. The measurements published by Keesom and Taconis[6] and by Reekie[7], however, are much too inaccurate to allow a direct comparison with theory. We wish to direct the attention of the experimentalists to this important problem.

IT occurred to me some time ago that the phenomenon of superfluidity might be qualitatively understood on the basis of the concept of de Broglie waves in analogy to the Ramsauer effect. At sufficiently low temperatures and consequently very small thermal velocities, the de Broglie wave-lengths of the atoms ought to become large compared with the atomic dimensions; thus the collision cross-sections of the atoms must become very small, and hence all those phenomena which are due to atomic collisions should become insignificant. Consequently, if a substance can exist in the 'liquid state' at all at such a low temperature, it will have a vanishingly small viscosity. I have pointed out this idea in discussions and lectures on the subject in the past, but did not think fit to publish it without a proper quantum-mechanical treatment. It is very satisfactory that this has now been done by Born and Green quite independently, and that the result of their theory essentially confirms the qualitative picture outlined above.

Infra-Red and Raman Spectrum of *Cyclo*-octatetraene

As part of work on the structure and properties of *cyclo*-octatetraene, we have recently measured the infra-red spectrum between 2 μ and 20 μ of the liquid and vapour and the Raman spectrum of the liquid. The sample was prepared specially for this purpose, and purified by repeated re-crystallization. The infra-red spectra were measured with single- and double-beam recording spectrometers using prisms of rock salt, fluorite and potassium bromide. The Raman spectrum was excited with the mercury line 5461 A., which lies to the long wave-length side of the onset of absorption, and photographed with a spectrograph having a large glass prism giving high resolution and medium dispersion.

The following Raman displacements were found (cm.$^{-1}$): 193(9), 294(4), 372(7), ? 488(0), 874(8), 950(5), 1205(5), 1440(2), 1655(10), 1740(1), 2950(5), 3003(10).

The infra-red bands found with the liquid were as follows (cm.$^{-1}$): 675(v.s.), 762(w.), 802(v.s.), 849(v.w.), 875(v.w.), 890(v.w.), 913(v.w.), 944(s.), 968(m.), 993(w.), 1033(w.), 1098(v.w.), 1140(v.w.), 1208(m.), 1228(m.), 1405(m.), 1580(m.), 1642(s.), 1734(m.), 1754(m.), 1789(w.), 1879(w.), 1922(w.), 2008(v.w.), 2340(v.w.), 2749(v.w.), 2789(v.w.), 2834(w.), 2970(m.), 3009(v.s.), 3281(v.w.).

With the vapour, at temperatures up to about 80° C., some of the bands showed a well-defined contour. Thus the intense liquid bands at 802 and 675 cm.$^{-1}$ each split into a three-branch type at 793, 802, 813 cm.$^{-1}$ and 659, 670 and 681 cm.$^{-1}$. The liquid bands at 944 and 968 cm.$^{-1}$ also showed contour which seems to be of the same type; but the branches overlap and the exact position of the sub-maxima observed may not be directly useful. Each of the bands at 1208, 1228 cm.$^{-1}$ found with the liquid appears to show contour, but overlapping again obscures it. Near 3 μ, bands were found with the vapour at 2745(v.w.), 2834(w.), 2970(m.) and 3019(v.s.).

It is hoped to carry out a normal co-ordinate treatment of the results, and a complete discussion is therefore postponed; but the following comments may be made. First, while the Raman intervals obtained agree well with those recently reported by Lippincott and Lord, we have been unable to observe many of the weak displacements listed by these authors. It is peculiar that we failed to observe their fairly strong Raman interval of 249 cm.$^{-1}$; but as regards the remaining weak lines given by them it is possible that our exciting radiation was not intense enough to make them noticeable, in spite of repeated trials. On the other hand, it is possible that some of the weaker lines reported by them were due to residual impurities, but against this it is noteworthy that at least some of the intervals correspond to infra-red bands observed by us.

It is quite certain that a number of 'coincidences' between the Raman and infra-red spectra of the liquid occur. Unless the selection rules break down with the liquid, this would preclude the presence of a centre of symmetry. Other factors likely to indicate the exact selection rules which operate are less obvious. We have considered the results in terms of the structures D_{2d}, D_{8h}, D_{4h}, D_4 and D_{4d}, and while no clear decision seems possible, are inclined to think that they are in best agreement with the non-planar cradle type D_{2d} structure.

The solid polymer formed from *cyclo*-octatetraene on standing has also been examined in the infra-red. The presence of strong bands near 10 μ and 3 μ suggests that it contains hydroxyl groups.

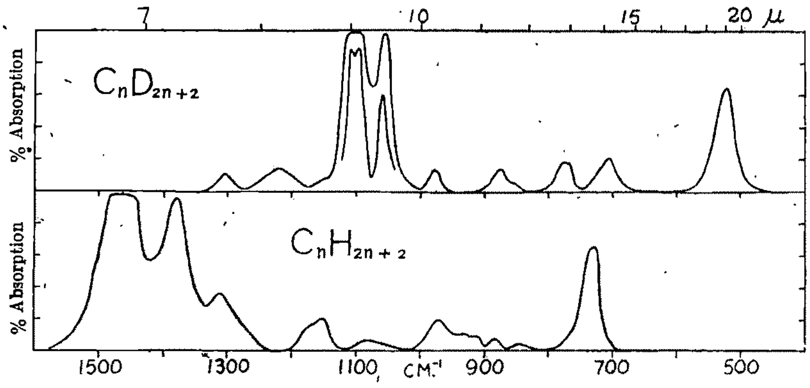
Infra-Red Spectrum of C_nD_{2n+2} and the 'Long-Chain Frequency' in Paraffins

THE most characteristic feature in the infra-red spectrum of any long-chain paraffin (C_nH_{2n+2}) is a strong band near 14 μ (725 cm.$^{-1}$). It was first noted by Coblentz[1], but Lecomte[2] and many other workers have directed attention to it, while an extensive investigation of hydrocarbons at Oxford and Cambridge[3] during the War showed that any molecule containing the group —$(CH_2)_n.CH_3$, in which n is equal to or greater than 3, possesses this band. So far as we are aware, no satisfactory interpretation of



this 'long-chain frequency' has yet been given[4], although it has been frequently assumed that it arises from a 'skeletal' vibration of the carbon atoms in the chain. The difficulty about this assignment is that the magnitude of the frequency is rather low for it to belong to a stretching mode of the carbon chain, and distinctly too high for it to be a deformation vibration. Recently, it has been suggested[5] that it is due to the overtone of a deformation vibration.

We have just investigated the infra-red spectrum of a fully deuterated long-chain paraffin and found, as expected, that all the bands well known to be due to vibrations of the hydrogen atoms (for example, those at 6·9 and 7·3 μ) were shifted to longer wave-lengths by approximately $\sqrt{2}$. However, we found that the band near 14 μ (725 cm.$^{-1}$) had also shifted and now appeared near 19 μ (522 cm.$^{-1}$), which corresponds almost exactly to lowering by $\sqrt{2}$. This proves conclusively that the 14 μ band in long-chain paraffins is not a skeletal frequency of the carbon chain but a vibration associated almost entirely with the hydrogen atoms. It seems most probable that it arises from a rocking vibration of the pairs of hydrogen atoms in the methylene (CH_2) groups, but a full discussion of the evidence for this interpretation will be published elsewhere.

We are much indebted to Mr. N. H. E. Ahlers for help in making some of the observations.

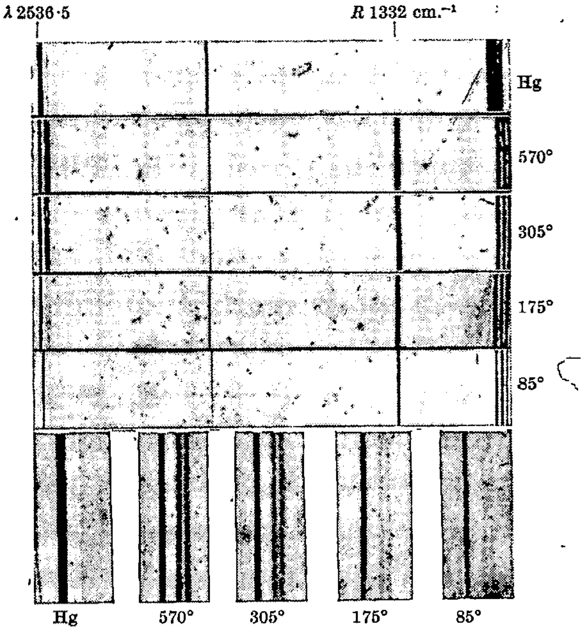
Thermal Scattering of Light in Diamond

RECENT determinations by Bhagavantam and Bhimasenachar[1] of the velocity of sound in diamond show it to be large, about 18,000 metres per sec. for longitudinal waves and about 9,600 metres per sec. for transverse waves along the (111) direction. A simple calculation using these values and the known refractive index of diamond ($\mu = 2 \cdot 61$) shows that the resulting Doppler displacements in the frequency of monochromatic light scattered transversely in diamond should be large enough to be recorded directly without interferometric aid using a quartz spectrograph of moderate power; the separation of the two components shifted in opposite directions would be 16 cm.$^{-1}$ for longitudinal waves and 8 cm.$^{-1}$ for transverse waves. These values refer to the case in which the λ 2536·5 radiation of the mercury arc in quartz is the incident radiation. A special advantage in using this radiation is that parasitic illumination of unaltered wave-length can be quenched by the use of a mercury vapour filter placed in front of the slit of the spectrograph, thereby enabling the Doppler-shifted components in the scattered light from within the crystal to be recorded without any intervening line of unaltered wave-length.



SCATTERING OF LIGHT IN DIAMOND AT DIFFERENT TEMPERATURES

These theoretical expectations are strikingly confirmed in experiment, as shown by the series of spectrograms reproduced herewith; the first of the series represents the incident radiation after quenching by a mercury vapour filter, and the following four are spectrograms of the transversely scattered light with the diamond held at various temperatures. These spectrograms were taken with a Hilger medium quartz spectrograph; the diamond was of the ultra-violet transparent type (No. 174 in Sir C. V. Raman's personal collection). The doubling of the 2536 line in the spectrograms is clearly seen, while in the lower reproduction the same effect is shown on an enlarged scale. It will be noticed from the upper reproduction that in contrast with the strong Raman line having a shift of 1332 cm.$^{-1}$, the intensity of which is practically unaffected by the change of temperature of the diamond, the Doppler-shifted lines become rapidly weaker with falling temperature. This is to be expected on theoretical grounds, since for them $h\nu_s \ll kT$, while for the Raman line $h\nu_r \gg kT$.

I have determined theoretically, with the aid of the recent determinations by Ramachandran[2] of the elasto-optical constants of diamond, the absolute intensity of scattering by the sound waves of thermal origin in diamond. It comes out to be of the same order of magnitude as that actually observed in these experiments, though an exact quantitative test of the theoretical formulæ is as yet lacking. It will be noticed that at all the temperatures actually employed, the Doppler-shifted components are much less intense than the Raman line arising from the principal lattice vibration.

X-Ray Spectra of Trans-Uranic Elements

In view of the recent discovery of elements with atomic numbers 93–96, it is of interest to recall a calculation based on the assumption of a minimum proper length for the world-line of an electron[1]. The conception that it is impossible to discriminate in space-time between two positions of the electron when the interval separating them is less than h/m_0c (m_0 = rest mass) leads to the result that an electron in a Bohr orbit cannot have a velocity greater than $c/\sqrt{2}$. A further consequence of this is that a K-ring cannot exist in an atom for which $Z > hc/2\sqrt{2}\pi e^2$; and this means that the Bohr–Rutherford model would stop at $Z = 96$. Although the original argument leading to this result cannot be regarded as free from objection in the light of modern quantum theory, the likelihood of some such limitation remains. A more recent application of the principle of minimum length and time to the Rutherford–Bohr atom sets the upper limit to Z somewhat lower than 96 [2].

According to a theory of the structure of the nucleus[3], a limit to Z occurs in the form $Z^2/A < 47{\cdot}8$, a result which suggests that this limit may actually be set by $Z^2/A < hc/4\sqrt{2}\pi e^2 = 48{\cdot}44$. From this, at any rate, it appears likely that nuclei occur with Z values higher than 96, and from what is known of the artificial production of trans-uranic elements it may be anticipated that such nuclei will be produced. Their life, however, may be short owing to the probability of spontaneous fission increasing rapidly with Z^2/A [4].

In view of what has been said above regarding possible anomalies in the K-rings of such atoms, it will be of interest to examine, if possible, the K and L radiations in their X-ray spectra in order to ascertain if the Moseley sequence of X-ray spectral lines shows a break at an element close to 96.

A New Criterion of Yielding in Metals

Several theoretical criteria of yielding have been proposed[1,2] and tested by comparing the stress values found experimentally just as yielding began under simple stress systems. For example, the ratio of simple shear yield stress to simple tensile yield stress T_0/S_0 is given variously by older theories as 1, 0·77, 0·50, 0·62, while experimentally for common engineering materials this ratio is found to be 0·56 approximately. A better fit to experiment is the theory credited jointly to Huber, von Mises and Hencky (ref. 1, p. 478), which for the above ratio gives $1/\sqrt{3} = 0{\cdot}577$. This theory stated in Hencky's form for the stress system S_{ii}, etc., when $i = 1, 2, 3$, $j = 2, 3, 1$, is

$$\Sigma[(S_{ii} - S_{jj})^2 + 6\,S_{ij}^2] = 2\,S_0^2$$

just as yielding is beginning. If the system of stresses is two-dimensional simple shear together with simple tension, then the Huber criterion gives an ellipse by plotting shear stress as ordinate and simple tension as abscissa. Experimental examination[3,4] shows the experimental values to lie approximately on the theoretical ellipse.

The Huber expression is not convenient analytically because it is not linear in the stresses. I noted this in my theory of post-yield stress-strain[5], but have only recently looked for another criterion that would have a linear form in the stresses. The form that follows came from reasoning that was stimulated by a new theory of large strains[6]. However, in this present communication I will merely show arbitrarily that a linear expression can fit the experimental evidence already quoted.

It is found that $T_0/S_0 = 1/[\sqrt{2}(1+q)] = 0{\cdot}56$ when Poisson's ratio, q, is 0·26, and departs slightly from this value as q varies from metal to metal. This value coincides with the experimental value quoted for common engineering metals.

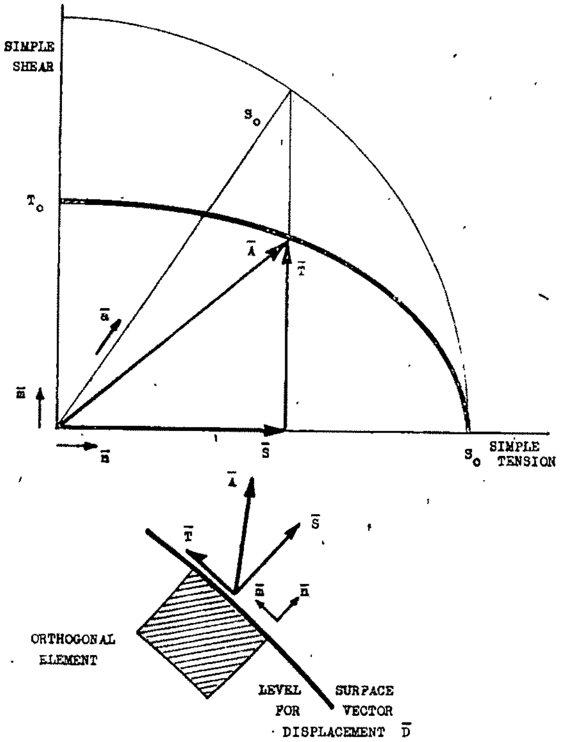
Now consider the ellipse of stress. For any general point stated in terms of the radial vector **a** and the vector stresses **S**, **T**,

$$(\mathbf{T} + \mathbf{S}) = \mathbf{a} \cdot \left[\frac{\mathbf{mm}}{\sqrt{2}(1+q)} + \mathbf{nn}\right] S_0,$$

where the dot indicates the scalar product of the unit vectors **a**, **m**, **n**. This defines the ellipse and reduces to the correct values for S_0, T_0, and hence satisfies the experimental values due to Taylor. Note that in Taylor's tests under simple tension and torsion the level surfaces of vector displacement[3] were planes normal to the longitudinal axis (that is, normal to **n** of the thin tubes used). However, in the general strained body, curved level surfaces of vector displacement are defined. In the simple experimental system or in the more general complex stress systems, the vector $\mathbf{A} = (\mathbf{S} + \mathbf{T})$ is the resultant stress on the face of an orthogonal element with that face in the level surface of vector displacement. In general, the element can be oriented so that **T** has no component normal to the plane of **m** and **n**.

Note that the discussion has been for the simple tensile yield stress S_0, using the first and fourth quadrants of the diagram. Equally well S_0 could be the compression yield, and then one would use the second and third quadrants of the diagram. This may be necessary, for example, with metals having a lower yield stress under compression than they have under tension.

The above linear expression in **S**, **T**, S_0 is suggested as a new criterion of yielding in the general complex



stress case. Such a linear form will allow easier analysis of many particular cases arising from the application of my theory of post-yield stress-strain[5]. In that theory the Huber criterion was used to give the simple tensile stress 'corresponding' to the complex stresses operating at any point in the yielded field. The new linear criterion can be used in the same way.

It is suggested tentatively that the criterion may apply to rupture, in which case S_0 is the simple tensile rupture stress for the metal. Examination of this hypothesis will require the analysis of stresses due to the usually large rupture deformations in some simple cases, and then comparison with the experimental values of the corresponding loads.

Hiedemann Patterns at Very High Frequencies

Diffraction patterns in liquids have recently been produced in this laboratory by using ultra-sonic waves of frequencies above 100 Mc./sec., and certain interesting features of such patterns have been studied[1]. With a 2-mm. tourmaline plate, frequencies up to 103 Mc./sec. are now communicated to a glass slab as sound waves and the corresponding diffraction patterns obtained by allowing light to pass through the glass slab, as was first done by Hiedemann[2], but at much lower frequencies. The thickness of the glass slab used in our investigations is such that at these frequencies it oscillates at about its 300th harmonic.

Patterns due both to longitudinal and torsional sound waves are obtained either individually or simultaneously. It has been found that by attaching a suitable oscillator plate such as a Y-cut quartz to the glass slab, the longitudinal wave may be suppressed and the torsional wave made prominent and so on. The polarization characters of such diffraction patterns already reported by Hiedemann and others have all been verified. In an earlier communication referred to above, we have reported that the sound wave in water at such high frequencies causes diffraction, which appears to be very much like reflexion in the Bragg sense. In these investigations, also, we have tried the effect of tilting the sound wave-front with reference to the incident light, and found that it introduces a marked asymmetry enhancing the intensity of the diffraction order on the appropriate side, but does not cause it to such an extent as altogether to extinguish the order on the opposite side at small inclinations, as has been found in water. This result is to be expected if we remember that the velocity of sound in glass is nearly four times as great as that in water, making the grating element at such high frequencies in the former four times as large as that in the latter. Consequently, effects due to tilting the sound wave-front obtained in glass at 100 Mc/sec. should be like those obtained in water at 25 Mc./sec. only, which is indeed the case.

The velocities obtained for longitudinal waves of four different frequencies and a torsional wave (46·46 Mc./sec.) in the glass slab are given below:

Frequency, in mc./sec.	13·24	20·74	47·04	103·55	46·46 (*T*)
Velocity, in km./sec.	6·01	6·02	6·02	6·04	3·68

Elastic moduli calculated from the above data are $Y = 8·03 \times 10^{11}$ dynes per sq. cm., $n = 3·34 \times 10^{11}$ dynes per sq. cm., and $\sigma = 0·201$.

Heat of Atomization of Carbon

In connexion with the series of communications under the above title[1], I wish to direct attention to an old paper which contains an accurate computation of the metastable ^5S state of the carbon atom[2]. The value given in that paper is 4·3 eV. above the ground-state of carbon, and the uncertainty is less than 0·1 eV. This is equivalent to 100 ± 2 kcal./mole.

The method of computation used in that paper is based on quantum mechanical perturbation theory. It differs radically from the usual iso-electronic extrapolation method, because it uses relations between energy states belonging to the same atom and its ions instead of comparing neighbouring atoms. The method gives surprisingly accurate predictions, especially for low levels of high multiplicity. For example, for the similar sp^3 ^5S levels in N II and O III, the computation yields 135 and 173 kcal./mole, whereas the observed values are 133 and 171 kcal./mole.

A comparison with these two examples and with many other cases gives an indication of the size and direction of the error in the computation. The most probable value for the ^5S state of carbon is close to 98 kcal./mole, in good agreement with Edlén's estimate of 94 ± 2 kcal./mole.

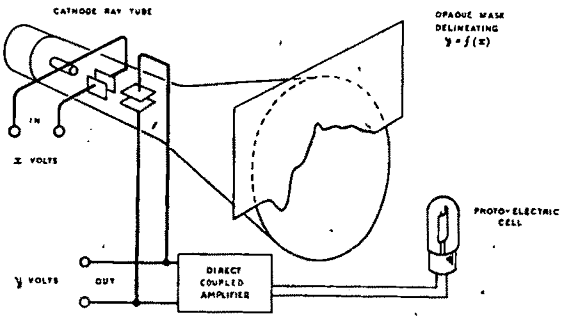
Electronic Function Generator

It is interesting to compare the accompanying diagram with that given by Mr. D. M. MacKay in a recent communication[1]. The present diagram is from the original sketch used in a paper I read to the Rugby Engineering Society on February 6, 1946[2]. This particular embodiment of the idea was demonstrated on the same occasion.



In addition to the applications mentioned by Mr. MacKay, it is possible to combine a pair of electronic function generators to form a high-speed electronic analogue multiplying unit. This aspect has been dealt with in an article which was accepted for publication[3] towards the end of 1946.

A provisional patent application was filed by me and the British Thomson-Houston Co., Ltd., early in 1946[4], and pre-dates the application quoted by Mr. MacKay by some ten months. A complete specification was filed on January 14 this year.

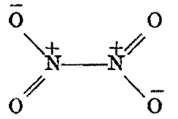
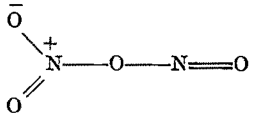
Constitutions of Dinitrogen Tetroxide and Trioxide

THE structure of dinitrogen tetroxide has recently been much discussed, but no clear conclusion has been reached. The structure of dinitrogen trioxide has less often been explicitly considered, but it, too, has remained uncertain.

In general terms, the position with regard to dinitrogen tetroxide has been that, while physical evidence has pointed to structure I, chemical evidence has been held to require some structure, such as II, which is capable of dividing, in addition reactions, to produce a nitroso-group *inter alia*. Structure III has been suggested, but not seriously supported. One proposal for satisfying both the physical and chemical requirements has been to assume forms such as I, II and III in equilibrium[1]. Structure IV represents a very special concept which has been introduced[2] in another attempt to reconcile the physical and chemical indications. (For simplicity, mesomeric states will be represented in each case by a principal valency structure.)



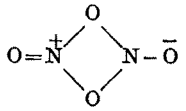
I



II

$O{=}N{-}O{-}O{-}N{=}O$

III

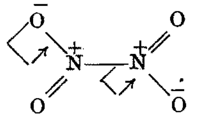


IV

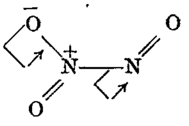
The main point of the chemical evidence has been that, according to the older organic chemical literature, a variety of groups, including nitroso-, nitro-, nitrito- and nitrato-groups, have been introduced into organic compounds by the action of dinitrogen tetroxide[3]. However, this evidence is largely annulled by the recent work of Levy and Scaife[4], from which it is clear that the complicated picture presented by the older literature is the result of an insufficiently exact control of experimental conditions. These authors show that there are but two primary products of the addition of dinitrogen tetroxide to simple olefins, namely, dinitro-compounds and nitro-nitrito-compounds, and that, in the latter products, the nitro-group attaches itself to that carbon atom which carries the larger number of hydrogen atoms. They conclude that, so far as their results are concerned, there is little to choose between formulæ I and II; but we are going to suggest that, considered in a somewhat wider setting, their work completes a chain of evidence leading to a more specific inference.

As regards physical evidence on the structure of dinitrogen tetroxide, some firm conclusions can be drawn from the spectroscopic work of Sutherland[5]. This shows that the molecule possesses a centre of symmetry, and that it has a low, very intense, Raman frequency, such as would arise from a weak central bond. It also excludes the presence, in any large amount, of any tautomer not fulfilling these conditions. This indicates formula I, though it does not clearly exclude either III or IV. (Mesomerism confers an NN-link on IV.) Formula I is also supported by Giauque and Kemp's measurements of the entropy of dinitrogen tetroxide[6]; and Hendricks has shown[7] that the same structure provides a consistent interpretation of Végard's X-ray data[8].

The additive reactivity of dinitrogen tetroxide shows that it is an electrophilic addendum, and adds in the successive parts nitronium ion and nitrite ion. The nitronium ion goes where a proton would in an addition of hydrogen chloride, and it necessarily forms a nitro-group, while the nitrite ion can attach itself to the remaining position either as a nitro- or as a nitrito-group. Either formula I or II can fulfil these conditions, and using formula I the necessary polarization is illustrated in V. We need not consider the question of the free life, if any, of the anionic component of the addendum, since this must depend on the precise conditions of each reaction. Levy and Scaife have found that dinitrogen trioxide adds to simple olefines to form nitro-nitroso-adducts, in which the nitro-group again attaches itself to the carbon atom carrying the greater number of hydrogen atoms. This shows that the trioxide is also an electrophilic addendum, and that it adds in the successive parts nitronium ion and 'monomeric hyponitrite' ion. The structure of dinitrogen trioxide, and its polarization in additions, are therefore as shown in formula VI; and the direction of polarization need cause no surprise, since LeFèvre[9] has pointed out that the tautomeric electron-attraction of the nitroso-group is greater than that of the nitro-group. Formula VI clearly accords with the blue colour of the trioxide, and, since N—N links in general are weak, with its ready dissociability. Finally, taking account of the auto-oxidation of dinitrogen trioxide to dinitrogen tetroxide at − 100°, and of the reduction of the latter by nitric oxide back to the trioxide at − 150° [10], one may conclude that dinitrogen tetroxide is correctly represented by formula V (= I).



V



VI

Thus, having regard to both the physical and chemical evidence, we feel that the long-debated question of the structures of the stable forms of these oxides may be regarded as settled.

Retinene$_2$ and Vitamin A$_2$

Retinene$_1$, first noted by Wald in his work on the visual-purple cycle, is the aldehyde of vitamin A [1], from which it has been prepared in high purity[2]. Retinene$_2$, the corresponding aldehyde of vitamin A$_2$, enters into the porphyropsin cycle of freshwater fish retinas. It has been obtained by fractionation of the aldehydes prepared from a mixture of vitamins A$_1$ and A$_2$ derived from ling-cod liver oil[3]. As described by Wald, retinene$_2$ shows $\lambda_{\text{max.}}$ 405 mμ in chloroform and 705 mμ in the antimony trichloride colour test. The preparation obtained by oxidation of vitamin A$_2$ by means of manganese dioxide shows $\lambda_{\text{max.}}$ 405 mμ (chloroform), 385 mμ (cyclohexane), and 720 mμ (antimony trichloride test) fading to 705 mμ.

If vitamin A is oxidized by means of aluminium tertiary butoxide (Oppenauer reaction) using benzene as solvent and diethyl ketone as hydrogen acceptor, a C$_{20}$ aldehyde is obtained[4,5]. This aldehyde cannot be distinguished from retinene$_2$. When fed to vitamin A-deficient rats, it gives rise in the lining of the small intestine and in the liver to a product showing the properties of vitamin A$_2$ ($\lambda\lambda_{\text{max.}}$ 345 mμ, 284 mμ; 693 mμ, antimony trichloride colour test). When retinene$_1$ is similarly treated with aluminium tertiary butoxide, the C$_{20}$ aldehyde is obtained in better yield.

Retinene$_2$, prepared from ling-cod liver oil (that is, from vitamin A$_2$) by oxidation with manganese dioxide, gives a crystalline 2,4-dinitrophenylhydrazone, m.p. 160–161°. The C$_{20}$ aldehyde prepared from vitamin A or retinene$_1$ gives the same compound (no depression in mixed melting point).

These experiments indicate that vitamin A$_2$ differs from vitamin A by one additional conjugated double bond situated in the ring. This agrees with the structure attributed to the C$_{20}$ aldehyde by Heilbron and his colleagues[4]. The aldehyde[6] corresponding in structure with Karrer's alternative formulation for vitamin A$_2$ is very different from retinene$_2$.

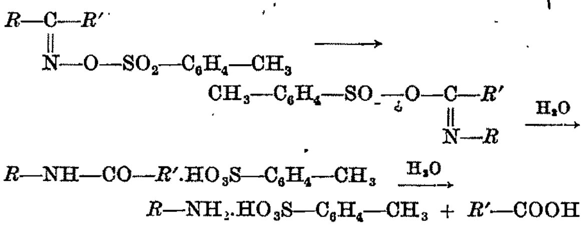
Conversion of 2-Aceto-furan to Hexen-2-dion-4,5-acetal-1 and Pyrocatechol

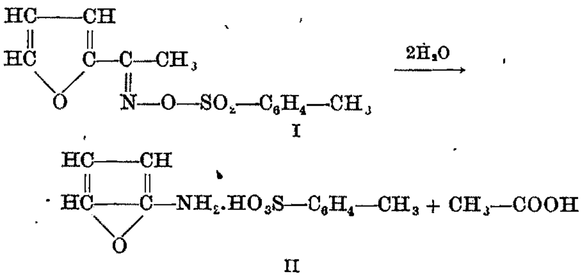
Several workers have already tried unsuccessfully to synthesize 2-amino-furan[1], probably because this compound decomposes very readily. Nevertheless, it was thought that the substance might be produced by a milder procedure. Therefore, we have tried to apply to furan derivatives the reaction discovered by P. W. Neber[2] on *p*-toluenesulphonyl derivatives of certain aromatic ketoximes, according to the following scheme.



$$R\text{—}\underset{\underset{\text{N—O—SO}_2\text{—C}_6\text{H}_4\text{—CH}_3}{\|}}{\text{C}}\text{—}R' \longrightarrow \text{CH}_3\text{—C}_6\text{H}_4\text{—SO}_2\text{—O—}\underset{\underset{\text{N—}R}{\|}}{\text{C}}\text{—}R' \xrightarrow{\text{H}_2\text{O}}$$

$$R\text{—NH—CO—}R'.\text{HO}_3\text{S—C}_6\text{H}_4\text{—CH}_3 \xrightarrow{\text{H}_2\text{O}} R\text{—NH}_2.\text{HO}_3\text{S—C}_6\text{H}_4\text{—CH}_3 + R'\text{—COOH}$$

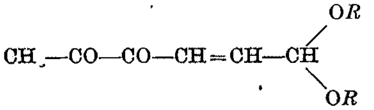
However, on shaking *p*-toluenesulphonyl 2-aceto-furan-oxime (I) with ethanol, not the expected 2-amino-furan or rather its toluenesulphonic acidic salt (II) was formed; but, in addition to toluenesulphonic acidic ammonium, a yellowish-green, strongly



I

II

reducing liquid, free of nitrogen, very sensitive to heat, which can be distilled *in vacuo* at constant temperature, without being decomposed. The analysis and determination of the molecular weight gave the elementary formula $C_{10}H_{18}O_4$ (III). Methanol, instead of ethanol, gives rise to a very similar, though different, substance with the formula $C\,H_{12}O_4$ (IV), showing the same properties as (III). The constitution and configuration of these interesting substances were determined by various methods, and they can be represented by the structural formulæ III and IV:



III

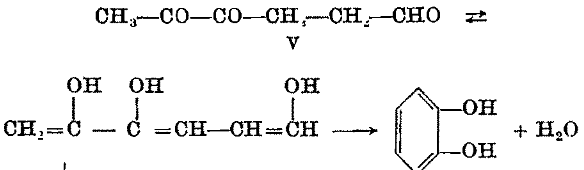
$R = -C_2H_5$. $R = -CH_3$

IV

III and IV are, therefore, to be designated as *cis*-hexen-2-dion-4,5-diethylacetal-1, and dimethylacetal-1, respectively.

In the course of our further work, we endeavoured to study the free aldehydes, corresponding with the acetals III and IV. However, the unsaturated diketo-aldehyde (*cis*-hexen-2-dion-4,5-al-1, CH_3—CO—CO—CH=CH—CHO) could not be produced by hydrolysis of III or IV, because the carbon chain between the carbonyl groups 4 and 5 splits up with formation of acetic acid, even in cold aqueous solution.

The hydrolysis of the saturated acetals (obtained by catalytic hydrogenation of III and IV) also leads to a surprising result; because instead of the expected diketo-aldehyde (hexen-dion-4,5-al-1, V) there was produced pyrocatechol, the formation of which, however, can easily be explained through the enol form VI:



V

VI

Since pyrocatechol and its derivatives are very common in Nature, it is perhaps of interest to show a possible way by which they can eventually be formed from carbohydrates through furan derivatives.

At present no definitive explanation can be given of the mechanism of the conversion of I to III and IV. It is very probable that the reaction does not go according to Neber's formulæ through 2-aminofuran, for by this means the formation of a six-membered carbon chain cannot be explained.

A more detailed description of these investigations will be published elsewhere.

Kinetics of Polymerization and Molecular Weight Distributions in Polymethyl Methacrylates

RECENTLY, Evans and co-workers[1,2] have examined the polymerization of methyl methacrylate in aqueous solution, when the initiation of polymerization was by hydrogen peroxide in the presence of ferrous ions. The suggested reaction scheme was as follows:

$$\begin{array}{lcl} H_2O_2 + Fe^{++} & \rightarrow & Fe^{+++} + OH + OH^- \\ M + OH & \rightarrow & A_1 \\ A_1 + M & \rightarrow & A_2 \\ A_{r-1} + M & \rightarrow & A_r \\ A_r + A_s & \rightarrow & P_{r+s} \end{array}$$

Algebraic expressions were derived giving the rate of disappearance of monomer and also the distribution of molecular weights in terms of concentrations and the rate constants of individual reaction steps.

Equations appropriate to this reaction scheme arise as special cases of the more general treatment previously given by us[3]. While the kinetic expressions which result from the general treatment are identical with those presented by Evans *et al.*[1,2], the molecular weight distribution function is obtained in a different form. In this note it is suggested that the equations for molecular weight distribution derived from the more general treatment[3] possess certain advantages over those proposed by Evans.

Adopting the same symbols as in the papers by Evans, and substituting in the appropriate distribution function for termination by combination which is given at the bottom of page 497 of ref. 3, there results the following equation:

$$P_r = \frac{a_0^3\beta^3}{2M_0^2}\, r \int_{M/M_0}^{1} \gamma^{3(\beta-1)} \exp\left(\frac{-a_0\beta}{M_0}\gamma^{\beta-1} r\right) d\gamma \qquad (1)$$

Equation (1) should be compared with the equation (17) presented by Evans *et al.*, which may be written as

$$P_r = \frac{a_0^3\beta^3}{2M_0^2}\,(r-2) \int_{M/M_0}^{1} \gamma^{3(\beta-1)} \left[1 + \frac{a_0\beta}{M_0}\gamma^{\beta-1}\right]^{-r} d\gamma \qquad (2)$$

Equation (1) can be written as

$$P_r = A_0 u^{-p}\,[I(u,p) - I(u(M/M_0)^{\beta-1}, p)] \qquad (3)$$

where $A_0 = \frac{1}{2} a_0\beta \left(\frac{a_0\beta}{M_0}\right)^{p+2} \left(\frac{\beta-1}{3\beta-2}\right)^{p/2} \Gamma(p+1)$;

$$p = \frac{2\beta-1}{\beta-1}; \quad u = \frac{a_0\beta}{M_0}\sqrt{\frac{\beta-1}{3\beta-2}} \cdot r;$$

$$I(u,p) = \frac{1}{\Gamma(p+1)} \int_0^{u\sqrt{p+1}} e^{-v} v^p dv.$$

The function $I(u,p)$ is the incomplete gamma function which has been tabulated over an extended range of the values of u and p by Pearson[4], so that the laborious graphical integration required by equation (2) can be avoided.

Moreover, inspection of equation (3) shows that if β is constant (that is, p is constant) and if M/M_0 (the fraction unconverted) is constant, then P_r can be expressed solely as a function of u provided A_0 (which is a function of M_0 and a_0) be suitably adjusted. Therefore, it follows that it is unnecessary to calculate P_r separately for different values of a_0, M_0 (when β and M/M_0 are constant), since the curves of P_r against r or rP_r against r can all be derived from a single one by a suitable multiplication of the scale of the r and P_r co-ordinates.

It is not possible to derive any simple expression for the value of r at which the maximum occurs in the rP_r against r curve, but it is possible to derive such a relationship for the occurrence of a maximum in the $r^{(2\beta - 1)/(\beta - 1)} P_r$ against r curve by simple differentiation. The maximum occurs at

$$r = \frac{M_0}{a_0\beta} \; \frac{3\beta - 2}{(M/M_0)^{\beta - 1} - 1} \ln (M/M_0). \quad (4)$$

Comparison of the calculated value of r from equation (4) with that derived from the experimental values of Evans gives $9 \cdot 2 \times 10^3$ calculated compared with 10×10^3 experimental. The agreement is rather better than the fit of the experimental and calculated curves from equation (3) as measured by the maximum in the rP_r against r curve, which occurs at $4 \cdot 5 \times 10^3$ (experimental) and at $3 \cdot 0 \times 10^3$ (calculated).

Thus it can be seen that by adopting the earlier general treatment, not only can the integration be expressed in terms of the well-tabulated incomplete gamma function, but also the variation of distribution with concentration of monomer and initiator can readily be derived. Further, this approach enables an additional test between theory and experiment to be made.

Ionic Exchange and Fibre Contraction

A $0 \cdot 2\,N$ aqueous solution of sodium alginate (molecular weight $\sim 10^5$) was extruded into $1\,N$ hydrochloric acid, thus producing alginic acid fibres, which were converted into calcium alginate by immersion in $M/10$ calcium acetate. The well-washed calcium alginate threads, fully swollen with water, contained $0 \cdot 37 \times 10^{-3}$ gm.-equiv. calcium per gm., the ratio of equivalent calcium to equivalent water-insoluble acid was 1·0, and the dry weight was about 8 per cent. These fibres were opaque, slightly elastic, birefringent and capable of heterogeneous cation exchange reactions in which a replacement of the calcium by other cations takes place.

During the study of this ion exchange under continuous flow conditions[1], it was observed that on replacement of the calcium by sodium or potassium a striking change of shape of the fibres takes place. An experiment of this kind was as follows. A calcium alginate thread, fully swollen with water, and 0·4 mm. in diameter, was hung over a hook and rinsed with $1\,N$ sodium carbonate, at a rate of flow of 2·0 cm.³/sec. During this treatment an initial contraction of the fibre, followed by a lengthening, took place, as shown below :

Time from start of flow (sec.)	0	5	10	20	30	40	50	60
Length of fibre (cm.)	14·0	13·4	13·0	12·6	12·2	12·5	13·3	14·6
Contraction (%)	0	4·5	7	10	13	11	5·5	−5

After 60 sec., the experiment was interrupted in order to weigh the fibre ; there was an increase of weight of about 20 per cent. In a control experiment, analyses were carried out after 30 sec., when the maximum contraction had occurred, and it was found that 29 per cent of the calcium had been converted into calcium carbonate, with simultaneous formation of sodium alginate. In estimating the calcium carbonate formed in this double decomposition, the fibre was immersed in water, and carbon dioxide was bubbled through the suspension ; the calcium carbonate was thus quantitatively converted into the soluble calcium bicarbonate, while the undecomposed calcium salts were treated with $1\,N$ hydrochloric acid, the calcium thus liberated being separately determined.

A similar shortening of various alginate fibres is also brought about by solutions of alkali phosphates, fluorides, oxalates or citrates. In some of these experiments, the contraction was as large as 20 per cent of the original fibre-length, and the weight of the fibre did not change during the shortening. The birefringence of the fibre decreased during the contraction, while the elasticity and the transparency increased. A few preliminary tests were also done under isometric conditions, when a force of at least 3 gm./mm.² was observed.

In attempting to explain these effects, it is assumed that the bivalent calcium ions form salt bridges between adjacent alginate chains, thereby building up a three-dimensional network in which the chains formed by repeating *d*-mannuronic acid residues must be relatively straight. On replacing some of the calcium by alkali ions, gel segments will be liberated, which are more flexible than the completely 'vulcanized' structure. The segments will be able, therefore, to take up configurations which are statistically more probable and in which the chains are curled up to a certain extent ; this will lead to a shortening of the fibre as a whole. The results obtained with other alginate fibres can be explained along similar lines, but it is not always possible to specify the nature of the inter-molecular cross-links.

In general, the contraction is regarded as a partial gel-sol transition, an interpretation which is also in accordance with the observed change of birefringence, transparency and elasticity. An important condition for fibre contraction appears to be that the replacement of calcium by alkali ions occurs rapidly. A number of experiments, to be described elsewhere, indicate that on slow replacement of the calcium by alkali ions no appreciable contraction of the fibres occurred, which is probably due to a predominating influence of plastic flow. The latter effect is perhaps mainly responsible for the lengthening of the fibres after contraction, but other reactions may also play a part during this stage of the ionic adsorption.

This investigation is being continued and extended to the study of protein and nucleoprotein fibres.

We are grateful to Prof. A. V. Hill for his interest in this work and to the Department of Scientific and Industrial Research for financial assistance.

Stability of Penicillin in Aqueous Solutions

WORK conducted in 1945 in the research laboratories of the Admiralty, but not then published, suggested that partially purified penicillin (calcium) from surface culture was more stable than the crystalline material. In addition, it was not found that phosphate, when included in penicillin solutions, produced any definite increase in the stability of the antibiotic.

The experiments were primarily carried out to obtain some information on the effect of solutions of different hydrogen ion concentrations on typical commercial samples of calcium penicillin as then being distributed at a potency of 362 units/mgm. Only when this work was under way did any information appear on the stability of penicillin solutions to various acidities. This work[1], however, applied to the crystalline sodium penicillin from submerged culture and stated that the pure material was more stable than the partially purified penicillin.

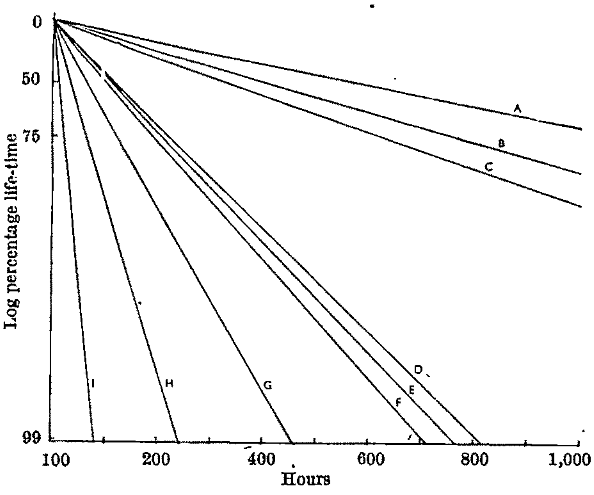
In the present work the stability of calcium penicillin was determined at each *p*H value from 2·00 to 10·0 in buffer solutions, these latter comprising:

*p*H 2·00 potassium chloride—hydrochloric acid.
3·00 potassium hydrogen phthalate and hydrochloric acid.
4·10, 5·00, 6·00 } potassium hydrogen phthalate—sodium hydroxide.
6·00, 7·00 } potassium dihydrogen phosphate—sodium hydroxide.
8·00, 9·00, 10·00 } boric acid—sodium hydroxide.

These were selected experimentally, and found to be most suitable for the work, in preliminary experiments in which the temperatures were only approximately maintained at the specified levels. All buffer solutions were checked immediately prior to use against a standard buffer solution of known value on a meter.

The experiments at 4° C. were conducted in the refrigerator as this provides the usual storage place; those at 27·7° C. and 37·4° C. being thermostatically controlled in water baths.

Two samples of the sterile dried calcium salt were dissolved in separate bottles of the required buffer solution at the specified temperature, the final concentration being 500 units/ml. One bottle was utilized for removal of samples for assay, the second being used to determine the variation, if any, of the *p*H during the experiment. Samples were removed from the first bottle into ice-cold buffer mixture so that the final *p*H was about 6·5, at which the sample was stable for assay. The assays were carried out by the absorptiometer method in addition to the cylinder plate process, both employing *S. aureus* as the test organism. The *p*H and sterility of both bottles were determined at the conclusion of the experiment.



A, *p*H 5, 4° C.; *B*, *p*H 7, 27° C.; *C*, *p*H 6, 27° C.
D, *p*H 7, 37° C.; *E*, *p*H 4, 4° C.; *F*, *p*H 6, 37° C.
G, *p*H 5, 27° C.; *H*, *p*H 8, 27° C.; *I*, *p*H 3, 4° C.
Graphs for other values have been obtained similarly.

Results. Concentrations of penicillin were plotted against time for each of the temperatures and *p*H values. From the graphs the life-times of the antibiotic were expressed as percentages of the initial concentration.

LIFE-TIME OF PENICILLIN IN HOURS

Temperature	4° C.		27·7° C.		37·4° C.	
	99%	50%	90%	50%	99%	50%
*p*H 2·00	14·4	2·15	1·24	0·2		
3·00	78·55	11·83	6·36	0·95		
4·10	773·0	114·0	72·0	11·0		
5·00		562·0	462·0	70·0		
6·00				334·0	712·0	107·0
7·00				402·0	820·0	126·0
8·00			241·0	36·0	74·6	11·3
9·00			64·7	9·7		
10·00			14·6	2·2		

Omissions indicate that no experiments were carried out at the particular temperature, or alternatively, at *p*H 5, 6, 7, the samples proved so stable that the experiments were discontinued after obtaining the 50 per cent life-times.

These life-times are shown in the accompanying table, which indicates the 50 per cent and 99 per cent life-times of calcium penicillin at the various *p*H values and temperatures. The figures illustrate the more rapid inactivation of the drug in alkaline than in acid solution in the range tested.

Penicillin proved so stable at *p*H 5·00–7·00 that no accurate experimental results were attempted for 99 per cent life-time of penicillin at *p*H 5·0 and 4° C. Likewise at *p*H 6·0 and 7·0 at 4° C. and 27·7° C.

In contrast to other workers it was found here that penicillin was more stable at *p*H 7·00 than 6·00, but whether this is due to an increased stabilizing effect of phosphate at the higher *p*H only is not certain. This higher stability at *p*H 7·00 is clearly shown at both temperatures. Furthermore, the pure sodium penicillin appeared to be less stable by direct comparison with partially purified penicillin (calcium) at 24·3° C., and also by indirect tests at 27·7° C. At *p*H values of 3, 4, 5, 9, 10, where temperatures of 27·7° C. and 37·4° C. only were employed, even indirect comparisons with the pure material of other workers were not legitimate due to the length of time occupied by the life-times of penicillin.

At *p*H 6·0 and 7·0 (both 27·7° C. and 37·4° C.), however, the calcium penicillin used here proved more stable than the pure sodium salt is stated to be at 24° C. and 37° C. Possibly the impurities act catalytically, being more active in alkaline than in acid solution and perhaps also being inert or 'stabilizers' in neutral solution.

Summarizing, it may be stated that the partially purified penicillin employed here is more stable in solution than the crystalline material is believed to be. That this increased stability is not due to the different type of salt used seems evident from the extensive work on penicillin salt stability published elsewhere[2].

In reference to the phosphate effect on stability, it may be noted that none of the buffer solutions had any deleterious action on penicillin. At *p*H 6·0 and 7·0, phosphate buffer solutions were employed, and a recent communication[3] suggests that some stabilization had been effected by these ions. Whether this was so may be judged from experiments carried out here at *p*H 6·0 using both a phosphate and a non-phosphate buffer solution for this acidity. In only one instance out of five did any slight increase in the life-time appear with the phosphate buffer as compared with the other solution. This, however, may have been due to an effect similar to that described recently[4], which stated that although remarkable success followed stabilization of sodium penicillin with phosphate, it was impossible to produce similar satisfactory results with calcium penicillin solutions.

I should like to express my gratitude to Surgeon-Captain Mussen, R.N., for permission to publish this work.

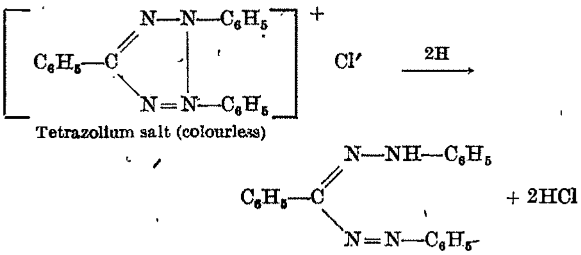
Tetrazolium Salt as a Seed Germination Indicator

A TOPOGRAPHICAL chemical test for germination was devised by Lakon[1] using sodium biselenite, which, on account of its toxicity, he rejected in favour of the tetrazolium salts[2]. Later, he evolved a technique for maize[3] with 2,3,5-triphenyl tetrazolium chloride, which was used in Germany during the War[4]. As information about other cereals was inadequate, a preliminary assessment of this compound as a germination indicator has now been made.

This tetrazolium salt is colourless, non-toxic, water-soluble, and easily reduced by either chemical or phytochemical means[5] to the triphenylformazan, an insoluble red dye.



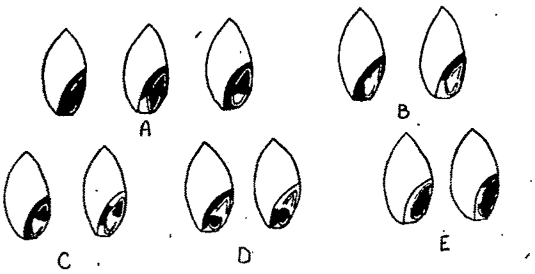
Tetrazolium salt (colourless)

Formazan (red)

When treated with an aqueous solution, the living tissues of germinating seeds are stained red; the conditions of the test being so arranged that the chemical processes of germination have already begun. In cereal seeds the whole of the embryo becomes stained, leaving the endosperm unaffected; whereas dicotyledonous seeds are stained completely.

The seeds are soaked in tap water overnight (18 hr.). Then they are cut through longitudinally in order to bisect the embryo. One half only of each seed is placed in a Petri dish (7 cm.), which just holds 100 grains or vetches, or 25 peas. Tetrazolium salt solution (1 per cent) is poured over them until every seed is just covered, and they are allowed to soak in the dark at 20° C. for 4 hr. The viable seeds have by now become stained, so the solution is poured off and the seeds, after washing with water, are examined individually.

In cereals other than maize, ability to germinate normally is indicated by staining of at least one half of the scutellum, the whole of the shoot part, and the transition part between root and shoot where the adventitious roots arise. The accompanying diagram indicates the types of staining encountered; only those in *A* are capable of normal germination. The same technique has been applied to peas and vetches.



STAINING REGIONS IN CEREAL SEEDS

A few typical results are set out in the accompanying table and compared with results obtained by the standard laboratory method.

COMPARISON OF TETRAZOLIUM AND GERMINATION TESTS

Seed	% Seeds capable of normal germination	
	Tetrazolium test	Standard germination test
Oats	85	88
Barley	97	98
Wheat (*a*)	99	99
(*b*)	39	40
Peas	97	97
Vetches	70	66

In the tetrazolium test, results are obtained within 24 hours as compared with ten days or more for the standard laboratory germination test. At the same time, latent causes of abnormality can be observed without any specialized botanical knowledge or skill, or elaborate apparatus. The method is more exacting and time-consuming for the individual worker, but against this must be set the advantage of obtaining a speedy evaluation of seed viability, either as a final or merely as a screening test.

A fuller account of this work will be published elsewhere.

I would like to express gratitude to Mr. C. C. Brett of the Official Seed Testing Station for his advice, and to the directors of May and Baker, Ltd., for permission to publish this communication.

New Aspects of the Action of Methylthiouracil

G. MANSFELD demonstrated[1] that in the serum of overheated animals a substance, thermothyrine A, is present which, injected into normal animals, decreases oxygen consumption. Serum of thyroidectomized animals has no effect.

I have shown[2] that thyroidectomized guinea pigs react to high environmental temperature by a more rapid, higher and prolonged hyperthermia than normal animals. This effect is not due to lack of thyroxine, because thyroxine enhances the effect of thyroidectomy on this reaction. Therefore, lack of thermothyrine A must be assumed as an explanation.

The fact that in later experiments similar results were obtained in animals treated with methylthiouracil raised the question whether methylthiouracil not only inhibits the formation of thyroxine but also the production of thermothyrine.

Dogs and rabbits were treated daily with 0·10 gm. per kgm. methylthiouracil for four weeks, and were then subjected for five hours to a temperature of 34–35° C., which raised their body temperature by 0·5–1·5° C. 2·5 c.c. of serum obtained at the end of the 5-hour period failed to reduce oxygen consumption of normal rats, while sera of untreated dogs and rabbits produced after similar exposure to high temperature a fall of oxygen consumption by 14–48 per cent. It is therefore evident that methylthiouracil inhibits the formation of both thyroxine and thermothyrine A.

The fact that thermothyrine A contains no iodine[3] proves conclusively that the action of thiouracil compounds cannot be exclusively an inhibition of iodinization.

A Rapid Supra-vital Staining Method for Assessing the Viability of Human Spermatozoa

We have developed a 4-minute technique for the supra-vital staining of spermatozoa which facilitates the estimation of viability and at the same time is suitable for the examination and counting of abnormal forms.

The method is based on the principle of Emmens[1] for rabbit spermatozoa which, however, is unsuitable for human material.

Method : Supra-vital stain, 50 c.c. distilled water; 1 gm. Revector Soluble Blue 706; 1·5 gm. glucose; 0·1 gm. sodium chloride; 0·3 gm. disodium hydrogen phosphate, hydrated; 0·005 gm. potassium dihydrogen phosphate, anhydrous. (This solution must be made up freshly; or alternatively it may be stored in 1 ml. ampoules and autoclaved.)

Counterstain : 1 per cent neutral red in distilled water.

Fixative : Half-volume saturated solution of mercuric chloride in distilled water; half-volume absolute alcohol; followed by 90 per cent alcohol containing a few drops of iodine in potassium iodide to give straw-coloured solution.

Four or five drops of seminal fluid are placed on a clean slide or in a small tube, and one drop of the supra-vital stain is added and well mixed. The mixture is left for 2–3 min. and one drop is withdrawn and a thin smear is made on a clean dry slide. The smear is allowed to dry in air, and is then fixed in the above fixative for 15–20 sec.; the slide is then dipped into alcoholic iodine, and into 90 per cent alcohol, and allowed to dry. The counter-staining is effected by putting the slide into neutral red for 15–30 sec., rinsing in water and differentiating *with care* in 90 per cent alcohol. The smear may then be dried and examined directly under oil immersion, or it may be passed through absolute alcohol and xylol and mounted in Canada balsam.

The nuclei of the spermatozoa which were dead when the seminal fluid was mixed with the stain are blue or purple; those that were alive are *clear* red, and a few non-nucleated forms remain unstained.

The stain does not kill living spermatozoa, since the motility of spermatozoa mixed with the soluble blue–Baker's fluid solution is unaffected. We have found motile spermatozoa in the stain after a period of 36 hours. The decrease in motility of sperm in the stain solution is of the same order as that of sperm in its own seminal fluid.

Two Symbiotes of *Psylla mali*

As a representative of Psyllid I selected *Psylla mali*, which, feeding on the apple tree, was easily available for investigation, and also for confirmatory work by other investigators. Profft[1] has published the best account that has appeared on symbiosis in this group of insects. On p. 312, in Fig. 19, he illustrates a section of the bacteriotome, called by him, in conformity with others, a mycetome. Unfortunately, the magnification of the section is only 165, which is exceptionally low for any cytological study. Further, he does not give any illustration of the symbiotes as seen in a smear of the tumour. In his illustration the majority of the tumour cells contain curved dark-staining objects. When I studied them in smears, stained with Giemsa, they appeared to be thick comma-shaped bacteria.

Profft's illustration, Fig. 19, also shows some tissue cells faintly stained, with contents very indistinct. These tumour cells contain very delicate and short bacteria which are best seen in smears stained with Giemsa.

A medium with apple juice was used for cultivating the symbiotic bacteria. The thick comma type of bacterium produced a bright green pigment like the colour of the insect. Morphologically, the tissue smear and that from the bacterial growth were identical. I noticed a cherry tree accidentally infected with *Psylla mali*; the insect which is usually green was now brownish-red. I made another medium with cherry extract. The medium was faintly coloured dirty pink. On plating, the comma-shaped symbiote of *P. mali* produced a bright cherry colour, like the colour of the insect feeding on the cherry tree. The share of the bacterium in producing a pigment derived from the food was thus evident.

The minor symbiote, the delicate bacterium, did not produce any pigment, and its role in the economy of the insect was not discovered.

This work was done some years ago, at Berlin, in the laboratory of Prof. F. F. Nord, now at Fordham University, New York. It is a pleasant duty to acknowledge his interest again here.

APPLIED BIOLOGY IN THE LEATHER INDUSTRY

THAT the leather industry forms an extensive field for research in applied chemistry has been well known for many years; that it forms a field, at least as extensive, for research in applied biology has been less well appreciated; and this notwithstanding the facts that the raw material of the industry is animal skin, that oils used by the industry and many tanning agents are plant products, that bacteria and moulds play havoc with certain of the processes of manufacture, and that insects cause damage to stored hides and finished leather. Clearly, in such an industry there must be opportunities for research in animal histology and physiology, as well as in microbiology, entomology and biochemistry; and some account of the problems presented in these various fields was given in a symposium held on March 21 at the Imperial College of Science and Technology by the Association of Applied Biologists in conjunction with the British Leather Manufacturers' Research Association.

The symposium was introduced by Sir Robert Pickard, who outlined the elaborate processes of leather manufacture, laying emphasis on the biological aspects and remarking that the problems of the industry call for co-operation between the statistician, the chemist, the physicist, the biologist and the psychologist, and directed attention to the fact that the tanner is handicapped by his raw material, the animal skin, over which he has very little control, as it is a by-product of other industries.

Discussing the factors that affect the animal skin, Mr. J. N. Turner stated that until comparatively recently the quality of skins received by the tanner did not vary greatly, and production of leather resolved itself into a relatively simple routine; but nowadays, with a wider market of supply and with advances in breeding and feeding techniques, many of which favour the milk- or meat-producing qualities of an animal at the expense of the leather-making properties of its skin, very wide variations are liable to occur that may necessitate certain changes in manufacture and in the resulting product. An acquaintance with recent trends in agricultural genetics and animal husbandry is therefore important to a modern leather manufacturer. It is only within the last decade that any attempt has been made to ascertain and measure the effects on the skin of cross-breeding and intensive feeding: for example, South African work has shown the effect of breed variations on the wearing quality of sole leather from cattle hides, and other work has indicated the effect of intensity of feed upon the fat content of hide and its bearing on grease stains in the finished leather. Differences in skin may also result from variations in climate and topography, and artificial changes may be induced by sex hormones, silicic acid or by compounds that stimulate mitosis.

Collagen, or white fibrous tissue, is the chief component of the animal skin from the leather industry's point of view. To the collagen fibres are due the properties of a leather, such as its tensile strength and resistance to abrasion; and much time has been devoted to the study of collagen by histologists and biochemists. In presenting some problems associated with reticulin, elastin and collagen in the skin, Miss M. Dempsey and Miss M. E. Garrod said that elastin and reticulin possess an importance out of all proportion to their amount. For reticulin fibrils that bind the collagen fibres together have a restrictive effect upon the swelling of collagen during the wide *p*H variations of the tannery processes; and elastin, which occurs in the skin chiefly in both the papillary and the innermost layers, has a particular effect on that outer part of the skin that eventually becomes the 'grain' layer of the leather. One of the difficulties in their investigations was to isolate pure samples of the fibres from the animal skin; consequently work was done, for example, on reticulin from adipose tissue, elastin from ligamentum nuchæ, and on collagen from rat-tail tendon, the binding sheath of which consists of both elastin and reticulin. They are not certain, however, that findings on these easily accessible tissues are directly applicable to similar tissues in the skin.

That the study of the surface chemistry of the animal skin is of importance and interest to the industry was indicated by Dr. K. G. A. Pankhurst. The conversion of animal skin to leather involves the three main constituents of the skin: protein, lipoid and water. The globular proteins are largely removed, the fibrous proteins are chemically modified by tanning, the natural lipoids are usually removed at an early stage of the process and are replaced by others at the end, and the water content is considerably reduced. Dr. Pankhurst pointed out that the three phases allow of six possible interfaces: protein–lipoid, protein–water, protein–air, lipoid–water, lipoid–air, protein–air; and each presents peculiar problems to the tanner. Leather is composed of an interlacing network of fibres that creates a system of *quasi* capillaries; consequently, as it is always necessary to have a full control over the kind of liquid that flows through them, a knowledge of the chemistry and physics of the flow of liquids is important in many leather-making problems. The penetration of a liquid into a fibrous structure is dependent on (*a*) the adhesion between fibre and liquid, (*b*) the surface tension of the liquid, and (*c*) the size and spacing of the fibres in the surface. The effective angle of contact that the liquid makes with the skin is an index of the penetrability of the liquid into it: if the angle is 90° or less the liquid will flow through; if it is greater than 90° the liquid will not flow through unless a certain pressure is applied to it. Penetration problems arise in the soaking of dried skins, the removal of lipoids from wet skins, the re-introduction of lipoids after tanning, waterproofing, etc.

One of the more curious processes in leather manufacture is that of 'bating'. It is a pretanning process in which tryptic enzymes are allowed to act on the skin. When it is properly done a characteristic silky smoothness is produced in the finished leather. From the earliest days of the industry, bating has been done with the dung of certain animals; but in more recent times the use of these unpleasant materials has been largely replaced by the appropriate enzymes. In dealing with the use of enzymes in the industry, Dr. E. W. Merry confined his attention to the bating process. The enzymes are obtained chiefly from pig pancreas, but ox pancreas, fish viscera, bacteria and fungi are also used. It has been shown that a preparation of pure chymotrypsin from pancreas can produce a typical bated effect in a skin. However, the mixed proteolytic enzymes in a bate have various effects on the different skin proteins: it appears that they affect, to greater or lesser degrees, elastin, collagen, keratin and perhaps reticulin, and it has been suggested that they have an important effect on the erector pili muscles in the skin. It seems not unlikely that, in the future, bates may be made up with specified enzymes, so that the different proteins of the skin may be preferentially attacked according to the class of leather desired.

Bacteria are notorious in the industry as the cause of putrefaction and, in the form of anthrax, as a danger to operatives. In their paper on this aspect, Dr. M. E. Robertson and Miss B. M. Haines said that putrefaction is usually prevented either by drying the hides after flaying or by treating them with sodium chloride as a preservative. The treatment of hides with a salt of marine origin, however, is likely to encourage a growth of red halophilic bacteria, known to tanners as 'red heat'; but this can be prevented by the addition of sodium fluoride to the salt. The use of disinfectants is also recommended in the process known as soaking, during which bacterial damage is especially common. The important process of liming kills all active stages of bacteria, but some spores (including those of anthrax) can survive; these can be killed by 'drumming' in lime and sodium sulphide at a raised temperature. Bacteria can, however, sometimes be of use to the industry: in America, bacteria producing lactic acid are used to promote the necessary acidity in the tan liquors, but in Great Britain the method is regarded as too difficult to control.

During many of the stages from skin to finished leather, mould fungi occur: except as a source of bating enzymes, they are a nuisance. The industry has also its insect pests, the chief being, perhaps, the beetles of the genus *Dermestes*. Mr. A. J. Musgrave, dealing with mycological and entomological problems, outlined the damage caused by fungi in the various processes. It is well known that vegetable-tanned leather is a better substrate for fungal growth than that which has been chrome-tanned; but the kind of processing a leather has received affects its liability to mould growth; moreover, there is need for a fuller acquaintance with the species of fungi that occur in the industry, and of the damage that they cause. A number of fungicides are available to the industry, which has wisely made use of available knowledge; and there are various ways in which fungicides can be incorporated in leather, though its multifarious uses make every proofing problem worthy of individual attention.

A considerable number of insects associated with the industry has been recorded. The chief pests seem to be warble flies, attacking the living skin, *Dermestes* beetles on dried hides, clothes-moths and carpet beetles on furs, and various insects attacking leather in the tropics. In addition, the fly *Piophila casei* is a considerable nuisance. It appears that the most systematic efforts at control have been those directed against *Dermestes* beetles: for many years arsenication of dried hides has been practised. The difficulties encountered in carrying out laboratory tests on insecticides and fungicides for the industry were discussed: some simple preliminary experiments have indicated that 'Gammexane' may be more toxic than D.D.T. to *Dermestes maculatus*.

Finally, when the leather has been manufactured, it may be found to be faulty in some way, or a tanner may realize during manufacture that there is some irregularity. A method in leather biology that is indispensable in investigating these faults and in controlling the various processes is a specialized branch of animal histology: the study of the fibre structure of skins and leather. In dealing with this subject, Miss M. Dempsey stipulated that it is the task of the student of fibre structure to attempt to correlate what he sees with the physical properties of the leather and with the kind of processing it has undergone. The condition of the collagen fibre bundles and their manner of interweaving constitutes, *sensu strictu*, the fibre structure of the leather: the history of a leather is written in the appearance of its fibre bundles. The properties of a leather, she said, are dependent on its fibre structure, the appearance of which not only gives information about the suitability of a process, but also indicates the quality of the leather, and, more important still, may reveal the cause of a flaw, such, for example, as skin disease or putrefaction, chemical breakdown during manufacture or maltreatment in use. The various features of fibre structure were described and their practical importance indicated.

A fuller account of this meeting is to be published in the *Annals of Applied Biology*.

RESEARCH AND INDUSTRY IN SCOTLAND

THE Scottish Regional Conference on "Research and the Progress of Industry in Scotland" arranged by the Federation of British Industries and held at the Merchants' Hall, Glasgow, on April 25, was on similar lines to that of the Midlands Regional Conference of the Federation at Birmingham in March. A message from Sir Edward Appleton wishing the Conference success contained, however, perhaps the most important statement made there. After indicating that the Department of Scientific and Industrial Research had been giving a good deal of attention to the question of the diffusion of scientific knowledge, and was looking to these conferences for guidance as to how best to deploy the limited scientific effort of Great Britain, Sir Edward said that to improve the Department's contacts with Scottish industry it is arranging to open a Scottish branch of the recently created Intelligence Division; and he cordially invited firms to discuss their special problems with the Department when that branch had been opened.

The morning session of the Conference considered the established industries of the region, Mr. W. Barr dealing with research in the steel industry, followed by Sir Wilfred Ayre on research in the shipbuilding industry and Mr. W. G. Marshall on research in the heavy engineering industries. Mr. Barr referred particularly to the recruitment of workers with technical knowledge in order that the results of research may be utilized. Steelmaking, so long practised as an art, is slowly becoming a science founded on the laws of physical chemistry, but much remains to be done before the desirable degree of control throughout the process is attained. Sir Wilfred Ayre, pointing out that the Scottish industry should not be differentiated from the larger British shipbuilding industry of which it is a part, suggested that the application of science in the industry would be facilitated if firms were readier to present the results of their research either in papers before technical institutions or to the industry's research association. He referred particularly to the valuable contribution of the various technical institutions, as well as to the work of the classification societies, and to the important part which the technical colleges might take in research. Private firms, however, must continue increasingly to carry out scientific work for themselves, and increasing numbers of their technical staff will require a more scientific training; and he stressed the need for planning so as to ensure that research work is at all times adequately prosecuted undisturbed by fluctuations in the prosperity of the industry. Commenting on the special problems of Scottish heavy industry, Mr. Marshall emphasized its comparative isolation from other industrial areas, the lack of variety of technical facilities, and of the skilled man-power and brain-power provided by light industry. It is thus the more important that the industry should make the fullest use of existing technical facilities. After reviewing the functions of an industrial research department, including the necessity of keeping abreast of research and development work elsewhere, and the qualifications of its staff, he briefly outlined the problems with which the research department of Messrs. Babcock and Wilcox, Ltd., is concerned. No section is entirely devoted either to routine or to research, and physics is of increasing importance in almost every branch of technology.

At the afternoon session, which considered broadly the balancing of Scotland's industries, Dr. J. W. McDavid reviewed the experience of the Explosives Division of Imperial Chemical Industries, Ltd., with nitrocellulose finishes, 'Cellofas', ethylcellulose, pentaerythritol, 'Ardil', etc., to indicate the way in which a live research and development department leads to new manufactures loosely but logically connected with the main industry. Dr. W. M. Cummings' paper, "Chemical Research for Scottish Industry", considered especially the needs of the small manufacturer who is characteristic of the region. The region is not big enough industrially to have several different research organisations, and while Dr. Cummings referred to the idea of establishing a research organisation in Scotland, working in close association with the Department of Scientific and Industrial Research, covering all branches of industry, engineering, building, coal, food, etc., he appeared to look rather to the technical colleges for greater assistance, and in particular he commended the example of the Joint Research Council established in Manchester. The idea could be extended with advantage in other areas, and should promote the contacts between industry and the technical colleges and universities which are all-important.

Mr. J. N. Toothill, discussing "Research in the Light Engineering Industries", commented on the effect of research and development on export policy and its assistance in securing balanced employment. It also helps to raise the standard of living of the community, and it can be an important factor in determining the location of industry. Mr. Toothill dealt with this idea in some detail, suggesting that in a new light industry, the growth of new products arising out of technical discoveries and appreciation of their market possibilities, and communications with market centres and centres of research, are more important influences on the location of industry than the supply of cheap raw material, adequate modern factory facilities and adequate, cheap and reliable supplies of electric power. At present, Scotland employs only 2·5 per cent of the total scientific man-power of the United Kingdom, as against a working population of 10 per cent, and new industries fail to grow in all areas distant from London. In this connexion, he referred to the tendency in the United States, and to some extent in Great Britain, to segregate the direction of policy, market research and technical research in areas near the national headquarters, leaving production to be carried out where labour is available.

In the final paper of the Conference, Prof. R. Hay, reviewing the individual Scottish firm and its application of research, pointed out that the first essential is a desire on the part of firms to utilize the advances already made in technical research. For small firms he suggested first the engagement of a professional consultant. For larger firms a technical development officer might be employed as technical adviser to the head of the firm, working in conjunction with established research associations, possibly supplemented by a small staff of his own. To meet the dearth of qualified men a co-operative effort of technical colleges and industry would be required, while finally Prof. Hay urged that industry in Scotland could with advantage develop a research centre on the lines of the Mellon Institute.

EMISSION OF RADIO-WAVES BY THE GALAXY AND THE SUN

By JOSEPH S. SHKLOVSKY

Sternberg Astronomical Institute of the Moscow State University

THE remarkable investigations of Reber[1], Southworth[2] and Appleton[3] have shown that radio-waves in the metre and centimetre region are emitted by the galaxy and the sun. Henyey's and Keenan's theory of long-wave emission by the galaxy[4] is based on the assumption that the mechanism of this emission is a free-free emission from interstellar gas. However, they have not correctly accounted for the absorption of radio-waves in the galaxy. Besides free-free absorption (which Henyey and Keenan took into account), there is an ordinary absorption of radio-waves because of damping oscillations of electrons in the field of radio-waves. The coefficient of absorption is given by

$$\alpha_\nu = \frac{\pi e^2 N_e}{m} \cdot \frac{1}{c} \frac{\gamma}{4\pi\nu^2 + (\gamma/2)^2}.$$

In interstellar space (and even more so in the solar atmosphere) the constant of damping γ is determined by the collision of electrons with ions. In this case

$$\gamma = 4N_i\sqrt{\frac{2\pi k T_\varepsilon}{m}} \cdot \frac{\pi}{2} \frac{e^4}{(kT_\varepsilon)^2} \ln \left(\frac{3}{2} \frac{kT_\varepsilon}{e^2 N_\varepsilon{}^{1/3}}\right),$$

where $N_i = N_e$, the concentration of ions, and T_ε is the electron temperature.

Solving the equation of transfer, we get the following expression for the intensity of galactic radio-emission :

$$I_\nu = \frac{2\nu^2 k T_\varepsilon}{c^2} (1 - e^{-\tau_\nu}),$$

where τ_ν is the optical depth of the galaxy in a given direction. Here the coefficient of absorption is accounted for in the above-mentioned manner.

Each intensity of a given optical depth of the galaxy in a given direction measured by Reber can be brought to a mutual correspondence. Assuming that $T_\varepsilon = 10{,}000°$, we find that the above-mentioned τ_ν changes from 0·48 (in Sagittarius, where the intensity is the highest) to 0·008 (in Perseus). For most regions of the Milky Way τ_ν is less than 0·1

Eddington and, in more detail, Strømgren showed[5] that interstellar hydrogen is ionized in the so-called zones of ionized hydrogen which surround the hot stars. According to Strømgren, the ratio of the volume of the zones of ionized and unionized hydrogen is 1/9. In the zones of ionized hydrogen N_e is[6] of the order of 2–4/cm.^{3}; in the zones of unionized hydrogen N_e is at least a hundred times smaller. Therefore, the zones of unionized hydrogen practically do not have any influence on the long-wave emission of the galaxy, as their optical depth is negligibly small. If the above-mentioned estimation of the ratio of both zones were correct, τ_ν would be much larger in all directions in the galaxy than those determined by Reber.

It can be supposed that the volume of the zones of ionized hydrogen given by Strømgren is too large. Strømgren extrapolated the relative number of hot stars observed in the vicinity of the sun to the whole galaxy. However, according to Baade[7], hot stars belong to the so-called 'first type' of population of the galaxies and are found only on the borders of the latter.

The optical depth of the solar atmosphere for radio-waves of different wave-length can be calculated. The optical depth of the chromosphere for $\lambda = 1$ cm. is 3×10^3; for $\lambda = 10$ cm., it is 3×10^5; and for $\lambda = 187$ cm., it is 10^8. Therefore, the chromosphere is not transparent for radio-waves. The optical depth of the corona for the same wave-lengths is correspondingly $1\cdot2 \times 10^{-4}$, 0·013 and 4·5, assuming that the electron temperature of the whole corona $T_e = 350{,}000^\circ$[8]. Therefore, the radiation in the centimetre range observed by Southworth is emitted mainly by the top layers of the chromosphere, that of the metre region (Reber) by the corona. However, if the temperature of the electrons of the whole corona were equal to 350,000°, the radio emission would be at least one hundred times larger than that measured by Reber. In order to bring theory and observations into accordance, it is necessary to assume that the electron temperature of the outer corona is relatively low and equal to about 3,500°. In this case the optical depth of the outer corona ($R/R_\odot > 3$) will be equal to 4·6. The outer corona will absorb intensely the radio emission of the 'hot' inner corona; its own emission will correspond to low temperature.

Recently Appleton[3] ascertained that at times the sun emits radiation $7 \text{ m.} < \lambda < 30$ m., the intensity of which is at least 10^4 times more than the intensity of a black body at $T = 6{,}000^\circ$. He connects this with bright eruptions in the solar atmosphere. This phenomena evidently could not take place if the emitter were a black body.

We suppose that in this case the proper vibrations of the plasma of the outer corona are the cause of radiation. This is based on the astonishing coincidence of the frequency of proper vibrations of the plasma given by Langmuir's formula:

$$\omega_L = \sqrt{\frac{4\pi e^2 N_e}{m}}$$

with that observed by Appleton's fellow-workers. Linder[9] showed that it was possible for longitudinal waves to be propagated in the plasma with a frequency close to ω_L. Every vibrating electron will emit radiation of frequency ω_L. This phenomena was observed by Penning[10], Ditmer[11] and others.

Proper vibrations of plasma may be caused by a flow of charged corpuscles, which move through the corona with a velocity more than that of sound. This was observed experimentally by Merill and Webb[12]; Vlasov[13] worked out a theory explaining the loss of energy of charged particles through their exciting proper vibrations. If the concentration of fast corpuscles necessary for exciting vibrations of the observed power is calculated, taking this theory as a basis, the derived values are fully reasonable.

If the proposed theory is correct, there must be a magnetic storm about one day after the outburst of the anomalous radio emission. After the above was written, I learned that this had been observed[14]. Another result of this theory is that the sun should emit, to a great extent, radiations in the decimetre range caused by proper vibrations of the plasma of protuberances and upper chromosphere. The corona only slightly absorbs this radiation. The 'decimetre' and 'metre' radiations should arise almost simultaneously. Entirely new possibilities for predicting geophysical phenomena are therefore revealed.

Details of this investigation are given in the *Russian Astronomical Journal*, **23**, No. 6, 333.

FORTHCOMING EVENTS

*(Meeting marked with an asterisk * is open to the public)*

Monday, June 2

UNIVERSITY COLLEGE, LONDON (at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Prof. R. O. Kapp: "The Presentation of Technical Information" (other lectures will be given on June 9, 16 and 23).*

Tuesday, June 3

ROYAL ANTHROPOLOGICAL INSTITUTE (at 21 Bedford Square, London, W.C.1), at 5.30 p.m.—Rev. W. J. Culshaw: "The Santals of Western Bengal".

Wednesday, June 4

PHYSICAL SOCIETY, COLOUR GROUP (at the Lighting Service Bureau, E.L.M.A., 2 Savoy Hill, London, W.C.2), at 3.30 p.m.—Mr. H. G. W. Harding: "The Colour Temperature of Light Sources".

INSTITUTE OF PETROLEUM (at the Royal Institution, 21 Albemarle Street, London, W.1), at 5.30 p.m.—Mr. R. P. Russell: Second Cadman Memorial Lecture.

SOCIETY OF CHEMICAL INDUSTRY, NUTRITION PANEL (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m.—Dr. Magnus Pyke: "Nutrition in Post-War Germany and Austria" (members of the Food Group are invited).

Thursday, June 5

FEDERATION OF BRITISH INDUSTRIES (at the Royal Victoria Hotel, Sheffield), at 10 a.m.—Regional Conference on "Industry and Research".

ROYAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Sir Thomas Merton, F.R.S.: "On Interference Microscopy"; Dr. S. Tolansky and Mr. W. L. Wilcock: "Interference Studies of Diamond Faces—A Crossed Fringe Technique".

CHEMICAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 7.30 p.m.—Scientific Papers.

Friday, June 6

SOCIETY OF CHEMICAL INDUSTRY, FOOD GROUP (joint meeting with the ROYAL SANITARY INSTITUTE, at the Torquay Natural History Museum, Babbacombe Road, Torquay), at 10 a.m.—Discussion on "The Microbiological Aspects of Food Quality" (to be opened by Prof. H. D. Kay, F.R.S.). (Meeting will constitute the Food and Nutrition Section of the Health Congress.)

INSTITUTION OF THE RUBBER INDUSTRY (at the Connaught Rooms, Great Queen Street, London, W.C.2), at 5.30 p.m.—Dr. Philip Schidrowitz: "The Impact of Synthesis on the Rubber Industry" (Second Foundation Lecture).

Chemical Society, Hull Local Section (joint meeting with the University College Scientific Society, in the Assembly Hall, University College, Hull), at 6.15 p.m.—Sir Ian Heilbron, F.R.S.: "Some Aspects of the Chemistry of Penicillin" (Inaugural Lecture).

Tuesday, June 3—Friday, June 6

Institute of Fuel (at the Royal Hall, Harrogate).—Conference on "Pulverised Fuel".

Tuesday, June 3

At 10.30 a.m.—Opening of the Conference; at 2.30 p.m.—First Session.

Wednesday, June 4

At 10 a.m.—Second Session; at 2.30 p.m.—Third Session.

Thursday, June 5

At 9.30 a.m.—Fourth Session.

Friday, June 6

At 10 a.m.—Fifth Session; at 2.30 p.m.—Closing Session.

Institute of Welding (at King's College, Newcastle-upon-Tyne).—North-East Coast Meeting. Visits and Technical Papers.

Saturday, June 7

Biochemical Society (in the Medical School, Hospitals Centre, Birmingham), at 1.30 p.m.—Scientific Papers.

Sunday, June 8

Institute of Economic Engineering (at the Waldorf Hotel, Aldwych, London, W.C.2), at 2.30 p.m.—Mr. E. H. Lewis: "Factors Affecting Output per Man-Hour".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Senior Assistant in Metallurgy in the Bradford Technical College—The Director of Education, Town Hall, Bradford (June 7).

Lecturer (temporary) in Zoology—The Secretary, University of Durham, 38 North Bailey, Durham (June 7).

Lecturer in Civil Engineering, a Lecturer in Mathematics, a Lecturer in Physics, a Lecturer in Chemistry, a Lecturer in Biology, and a Lecturer in Electrical Engineering, at the Brighton Technical College—The Education Officer, Education Office, 54 Old Steine, Brighton 1 (June 7).

Junior Physicist to take part in the clinical, teaching and research work of the Physics Department, and a Physicist to assist in research on application of physics to medicine—The Secretary, Royal Cancer Hospital (Free), Fulham Road, London S.W.3 (June 9).

Lecturer in Mathematics—The Clerk to the Governors, South-East Essex Technical College, Longbridge Road, Dagenham (June 9).

Principal Scientific Officer at the Royal Observatory, Blackford Hill, Edinburgh—The Secretary, Civil Service Commission, 6 Burlington Gardens, London, W.1, quoting No. 1916 (June 10).

Assistant Registrar—The Secretary, Imperial College of Science and Technology, Prince Consort Road, London, S.W.7 (June 13).

Provincial Specialist Advisory Officers, Assistant Advisory Officers, and District Advisory Officers, in the National Agricultural Advisory Service—The Secretary, Ministry of Agriculture and Fisheries, 4 Bickenhall Mansions, London, W.1, endorsed 'N.A.A.S.' (June 14).

May and Baker Research Fellowship in the Department of Physical Sciences—The Registrar, Wye College, Wye, Ashford, Kent (June 14).

Lecturer in Biology, and a Lecturer in Chemistry—The Clerk to the Governors, Woolwich Polytechnic, Woolwich, London, S.E.18 (June 14).

Chemist to take charge of the Plant Protective Chemistry Section—The Secretary, East Malling Research Station, East Malling, Maidstone, Kent (June 14).

Lecturer in Applied Mathematics—The Registrar, King's College, Newcastle-upon-Tyne (June 14).

Assistant Psychologist in the Research Unit of the Civil Service Commission—The Secretary, Civil Service Commission, 6 Burlington Gardens, London, W.1, quoting No. 1890 (June 14).

Demonstrator in Chemical Pathology—The Registrar, The University, Leeds 2 (June 15).

Grisedale Scholarship for Research in Botany or Zoology—The Registrar, The University, Manchester (June 20).

Assistant Physicist in the Radiotherapy Department—The House Governor, London Hospital, Whitechapel, London, E.1 (June 20).

Assistant Lecturers in Physics and Geology, Research Demonstrators (part-time) in Physics and Chemistry, and an Assistant Lecturer in Mathematics—The Registrar, University College, Singleton Park, Swansea June 21).

Lecturer in Geology, a Lecturer in Physiology, and a Demonstrator in Geology—The Secretary, Queen's University, Belfast (June 21).

Assistant Keeper in Egyptology in the Manchester Museum—The Registrar, The University, Manchester 13 (June 21).

Lecturer in Physical Chemistry—The Registrar, The University, Reading (June 23).

Lecturer in Physics—The Registrar, The University, Manchester 13 (June 28).

Agriculturist, and a Plant Breeder, in the Department of Agriculture, Southern Rhodesia—The Secretary, Office of the High Commissioner for Southern Rhodesia, Rhodesia House, 429 Strand, London, W.C.2 (June 30).

Assistant Lecturer in Geology—The Registrar, The University, Reading (June 30).

Principal Research Officer in the Engineering Division of the National Building Research Institute—The Secretary-Treasurer, Council for Scientific and Industrial Research, Private Bag 189, Pretoria, South Africa (June 30).

Botanist—The Director, Imperial Bureau of Plant Breeding and Genetics, School of Agriculture, Cambridge (June 30).

Director of Sugar Technological Research at Trinidad—The Secretary, Imperial College of Tropical Agriculture, Grand Buildings, Trafalgar Square, London, W.C.2 (June 30).

McRobert Research Fellow to undertake research relating to any disease that is generally regarded as malignant or incurable in Bacteriology, Biology, Chemistry, Chemotherapy, Clinical Science, Pathology or Physics—The Secretary, The University, Aberdeen (June 30).

Lecturer in Civil Engineering, and a Lecturer in Mechanical Engineering—The Director, Robert Gordon's Technical College, Aberdeen (June 30).

Chair of Anatomy at Charing Cross Hospital Medical School—The Academic Registrar, University of London, Senate House, London, W.C.1 (July 1).

Senior Lecturer, a Lecturer or Assistant Lecturer, and an Assistant Lecturer or Demonstrator, in the Department of Glass Technology—The Registrar, The University, Sheffield (July 1).

Professor of Botany, a Professor of Zoology, and a Professor of Civil Engineering, in the University of Ceylon—The Secretary, Inter-University Council, 8 Park Street, London, W.1 (July 1).

Shell Studentship in Geophysics—Dr. E. C. Bullard, Department of Geodesy and Geophysics, Cambridge (July 1).

Chair of Public Administration at the London School of Economics and Political Science—The Academic Registrar, University of London, Senate House, London, W.C.1 (July 3).

Chair of Theoretical Physics—The Registrar, The University, Liverpool (July 7).

Forest Officers (5) in the Forestry Division of the Department of Agriculture and Lands, Southern Rhodesia—The Secretary, Office of the High Commissioner for Southern Rhodesia, Rhodesia House, 429 Strand, London, W.C.2 (July 12).

Lecturers in Physics, Botany, Zoology, Geology, and Assistant Lecturers in Mathematics, Physics, Chemistry, Botany, Geology, Geography, Engineering—The Registrar, University College, Nottingham.

Physicist (male or female) to the X-Ray Therapy and Radium Centre, St. Luke's Hospital, Guildford—The County Medical Officer, County Hall, Kingston-on-Thames.

Physical Chemist (male) for fundamental research on high-temperature reactions involving iron and other elements—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W.1.

Physicist (mainly in connexion with radium and X-ray therapy)—The Secretary, Samaritan Free Hospital for Women, Marylebone Road, London, N.W.1.

Technician in the Museum and Histological Departments—The House Governor, Hospital for Sick Children, Great Ormond Street, London, W.C.1.

Lecturer in Pharmacy—The Secretary, Royal Technical College, Glasgow.

Laboratory Technician (Grade C) in the Physiology Department—The Warden and Secretary, London (Royal Free Hospital) School of Medicine for Women, 8 Hunter Street, London, W.C.1.

Secretary—The Director of Research, British Baking Industries Research Association, Wellington House, 125–130 Strand, London, W.C.2.

UNIVERSITY PLANNING IN GREAT BRITAIN

IN replying to the debate on the development of the universities in the House of Lords on May 14, the Lord Chancellor said little that added to what is already known regarding the plans and intentions of the Government. Nevertheless, in referring to the comparisons which are continually being made about the size of the university population in Great Britain and other countries, he did well to emphasize that such comparisons can be misleading "unless one realizes exactly what is meant by university education". The real meaning of that extraordinary American figure of one in 125 going to a university is rarely understood. In expressing his belief that there is a strong case for following the Americans "in having whole-time education up to university age", Lord Lindsay of Birker categorically declared that "many of the institutions to which these American undergraduates go we should not consider universities". Discussing the problems raised by the existence of these institutions, Dr. R. M. Hutchins, chancellor of the University of Chicago, wrote recently in *The Observer* : "The United States has led the way in providing education for all the people, and this provision is certainly a milestone on the march along what is called the Democratic Way of Life. In fact, however, this provision is both too little and too much. It is too little because it rests on the assumption that if no or low fees are charged education is free. It is too much because it is indiscriminate."

It was not, however, for purely academic reasons that the Lord Chancellor resisted the plea of Lord Lindsay of Birker that an independent Government Committee should be appointed to review university policy. The refrain of his speech was that the powers of the University Grants Committee have been so extended that it is now able "to assist, in consultation with the universities and other bodies concerned, the preparation and execution of such plans for the development of the universities as may from time to time be required in order to ensure that they are fully adequate to national needs" ; and that, since there is no immediate likelihood of the latest estimates of the needs of the universities prepared by the University Grants Committee being met, nothing is to be gained by the appointment of another committee. "The real trouble," said the Lord Chancellor, "is the building problem" ; and, as this is no short-term problem, the outlook is indeed gloomy. The University Grants Committee estimates that the developments which the universities are willing to undertake in the next five years will require £50,000,000, four-fifths of which is for the erection and equipping of new buildings. While the Chancellor of the Exchequer has accepted that estimate and expressed his willingness to find the money, the Minister of Works does not believe that, even if university building is given a high priority, more than £20,000,000 of building will be possible in this period. The most that he is prepared to promise is that he is willing to review the position from year to year.

This emphasis which the Lord Chancellor chose to place on the building problem has had the unfortunate effect of obscuring the larger and more fundamental questions which Lord Lindsay of Birker raised in opening the debate. Are we quite sure that the present framework of university education should be merely perpetuated ? Is there not room for further experiment ? Is there a place for institutions like the *Écoles des Sciences Politiques* or *des Études Polytechniques* of France, or the great German *Handelshochschule* ? Are the schools providing enough boys and girls of the right type to permit a doubling of numbers in the universities without a lowering of standards ? Is there any assurance of a demand for their services once they have passed through the universities ? These are, in the view of Lord Lindsay of Birker, some of the questions which require investigation ; and it is scarcely surprising that he should ask whether a committee the business of which it is year by year to consider grants to the universities is "the best committee to look at the whole set-up, with the idea, perhaps, of some revolutionary change".

One difficulty in charging the University Grants Committee with the responsibility of making policy decisions is what *The Economist* has called its "passive acceptance" of the suggestions offered by the universities and the Committee of Vice-Chancellors and Principals. "It could never," says *The Economist*, "compel London University to break itself up against its will ; neither is it prepared to go against the advice of the Vice-Chancellor's Committee that it is better to concentrate resources in the existing institutions than to dissipate limited reserves of personnel and materials on entirely new ones." Although it has given favourable consideration to the proposed experiment at Stoke-on-Trent, the wording of the resolution which has been communicated to the sponsors of the scheme deserves to be noted : "That the committee would consider sympathetically an application for financial assistance in respect of a new university college in North Staffordshire, provided that the basis of studies in science and art be adequately broadened". And again : "If this scheme is to include the conferment of degrees by the college, the committee will wish to be satisfied that adequate arrangements have been made for sponsorship by a university or universities". In short, although the promoters of the scheme drafted it in the belief that "a local university college should have a close relation to the distinctive characteristics of the locality it serves", the University Grants Committee has, in effect, replied that there must be more evidence of conformity to the *status quo*. In making this request the Committee may be wise ; but, if *The Economist* is right in its assertions, it is not easy to believe that the proposals have been subjected to impartial and independent examination.

Even more difficult—and certainly not less pressing—is the problem of the co-ordination of the work of the universities and technical colleges ; and its speedy solution would seem impossible without the creation of such a committee as Lord Lindsay of Birker requested. Indeed, it might well be argued that the full and satisfactory implementation of the findings of the Percy Committee on Higher Technological Education will otherwise prove impracticable. While that Committee did recommend the selection of a strictly limited number of technical colleges in which there should be developed technological courses of a standard comparable with that of university courses, Lord Eustace Percy alone suggested that the Government should adopt the policy of developing certain colleges into major university institutions. It may be true, as the Lord Chancellor hinted, that, "if the recommendations of the Percy Committee for a National Council of Technology are implemented (as there is every reason to think they may be), it would be one of the functions of that council to consider whether such a policy of up-grading is feasible, and if so, how it could best be carried out" ; but what guarantee at present exists that the status of university institutions would not be denied to those colleges which were up-graded unless "the basis of studies in science and art be adequately broadened" ?

Yet another aspect of this problem of the need for a body specifically charged with the task of co-ordinating policy was noted by Dr. Eric James, high master of Manchester Grammar School, at the conference on "The Place of Universities in the Community" arranged by the British Association and held at the University of Manchester on May 10. As already noted in *Nature* (of May 24), Dr. James urged that the work of the Barlow Committee is incomplete because no evidence was taken from schools as to their capacity to provide the requisite number of potential science graduates. In assuming that there is a waste of intelligence and talent, he may be right ; and, if he is, there is a pressing need to discover at what stage of education the wastage occurs. On the other hand, Lord Lindsay of Birker does not share this view. In discussing the extension of secondary education under the Education Act, he remarked : "As anyone concerned with education—particularly secondary education—is aware, the problem which arises from this reform is : Can we combine a high standard of English secondary education with a great increase in numbers—a threefold increase in numbers ? . . . I do not believe we could, for one moment, have multiplied the pupils going to grammar schools without affecting the standard of the grammar schools."

Important as this question undoubtedly is, it is even more important to know the real requirements of the nation for different kinds of scientific, technical, professional and managerial skill. Although certain professional bodies have made their own estimates—the Ministry of Education for teachers and the Goodenough Committee for medical men—neither the Barlow Committee nor the Hankey Committee tried to break up the whole requirements into detailed specialities. More recently, the Urwick Committee, in its report on "Education for Management" (H.M. Stationery Office. 6*d*.), has failed lamentably to find answers to the vital questions—the numbers engaged in management, the future demand for managers, and the experience of training for management gained in other countries. Without some clear indication of the national need for physicists, chemists, metallurgists, statisticians, economists or managers it is impossible for the universities to know whether they are over-expanding or under-expanding particular departments. It may, for example, be the sheerest folly to insist that "the basis of studies in science and art be adequately broadened", and that the traditional balance of studies should continue to be maintained. The answer to these questions will not be found until some body has the primary responsibility of co-ordinating and expanding the findings of existing reports and of presenting a comprehensive picture of the needs and opportunities in the field of higher education.

Least of all should it be forgotten that the task of university education is not to transmit an established body of knowledge. The university must do infinitely more than teach facts and theories. It must help the student to develop his faculties; it must train him to think independently that he may form his own judgments; and it must teach him methods of study that will enable him to keep pace with developments. In the medieval *disputatio* professor and students discussed a subject, weighing the pros and cons of an argument. While that form of teaching has its modern counterpart, the expansion of scientific teaching has resulted in new forms of academic instruction unknown to the medieval university. These methods are as applicable to the social as to the natural sciences. Political science divorced from field work in parliaments and government offices cannot be taught efficiently. Economics is a dead subject if the student has no opportunity to watch the process of production and distribution in mines, factories, shops, and the stock exchange; and if sociology is to be more than the philosophy of history it requires still more extensive field work. These principles are accepted in theory. How far they are being applied is still another question that requires to be answered.

TRIUMPHS OF THE BIRD PHOTOGRAPHER

Masterpieces of Bird Photography

Edited by Eric Hosking and Harold Lowes. Pp. 144 (63 plates). (London: Wm. Collins, Sons and Co., Ltd., 1947.) 12*s*. 6*d*. net.

HAD this book been published in 1939 I believe we should have seen a higher standard of reproduction of the various outstanding photographs of birds which render it a remarkable volume. But the difficulties of post-war production are not the only ones which cropped up—some of the negatives of the earlier photographers have been irretrievably lost, and reproduction had to be made from existing prints. That fine photograph, for example, of the pair of golden eagles at the eyrie together, taken by the late A. J. Rooker Roberts, would, I am sure, have been much better reproduced had the negative been found. The book is largely the work of members of the Zoological Photographic Club, to which the volume is dedicated. The birds shown are all British birds, although some of them have been photographed abroad. The reproduction of the snow goose, for example, was taken in Greenland by the late David Haig-Thomas, and William Farren's spoonbill was secured in the Marismas of Andalusia.

As is perhaps unavoidable, the standard of the photographs is uneven; some are without distinction, but a considerable number are good and some of them are excellent. To my mind, for sheer beauty and artistic perfection, the photograph of the kittiwake on the wing, taken by John Barlee, is supreme.

Some of the photographs reproduced are historic. We are shown, for example, what is the first ornithological photograph taken—that of a song thrush's nest by the late Cherry Kearton, exposed on April 11, 1892—fifty-five years ago. Here, too, is reproduced the first photograph ever taken of a bird on the nest—the bird is a lapwing, and was photographed by the late R. B. Lodge in 1895, by remote control, for 'hides' had not then been invented. All of us who are bird photographers are in the debt of that grand pioneer in Nature photography, the late Richard Kearton, who did more than any man to encourage a love for birds. Some of his photographs are still outstanding; but many of his best negatives have been lost, otherwise a more striking one than that here reproduced—a bullfinch on the nest—might have been chosen. Curiously enough, I was the means of that picture being taken. The bullfinch was nesting in our garden in Aberdeenshire and was so tame that she sometimes rose from the nest to take hemp seed held between my lips. I was a boy at the time (the date of the photograph, by the way, is earlier than that mentioned, 1908) and had telegraphed Kearton to come and photograph a ptarmigan's nest which I had found. One of Kearton's legs, on account of a fall from a tree, was six inches shorter than the other, and few persons with that handicap would have climbed to a height of more than 3,000 feet. The climb took us all night, and Kearton carried his heavy camera on his shoulder, on its stand all ready for use.

The Kearton brothers—Richard and Cherry—were the first to see the possibilities of a 'hide' for bird photography, and experimented with one made of the skin of an ox stretched over a hollow frame.

Perhaps the most interesting photograph in the book, from a historic point of view, is that taken by the late Cherry Kearton of a pair of ospreys at their tree eyrie on Loch Arkaig, one of the last British nesting haunts of this beautiful bird, now lost to us through the inroads of the man with the gun and the egg collector.

Most of those whose photographs illustrate this book are members of the Zoological Photographic Club: one misses the work of certain well-known photographers, such as R. M. Lockley, who has taken some remarkable shearwater photographs.

Most of the photographs are of birds at the nest, but on page 49 there is a striking picture, which it must have taken great patience to obtain, of a mixed party of knot, curlew, oyster-catcher and bar-tailed godwit at the edge of the tide. It is a really remarkable photograph, and can be appreciated to the full only by bird photographers themselves. Of the outstanding photographs of birds at the nest there is, on p. 55, an excellent photograph of a female hen-harrier at the nest by T. M. Fowler, and, on p. 69, a remarkable photograph of a male Montagu's harrier carrying home food. This was taken by Walter E. Higham. Eric Hosking lives up to his high standard of bird photography by his picture (p. 73) of a barn owl taken by flashlight. Fred Jefferson shows (p. 77) a fine photograph of a water ousel, taken at close range, bringing a billful of food to her family, and Arthur Gilpin (p. 63) has been most successful with a very difficult subject—a tree creeper.

Two photographs from the portfolios of the late G. B. Kearey are shown, one of them a singularly beautiful picture of a hen capercaillie—a shy and difficult bird to photograph—approaching the nest.

We are shown the late C. J. King's classic photograph of a greater black-backed gull, taken so long ago as 1910—a grand picture. One of the most beautiful photographs in the book is that of a sand-martin taken by L. H. R. Lowes ; one cannot look too long at it. Perhaps the rarest photograph, which must have been most difficult to take, is that (p. 99) of a chough, taken by W. W. Nicholas. The chough, nesting in caves, is a hard bird to picture, and I do not remember having seen a good photograph of it before. Niall Rankin's classic photograph of a gannet alighting at the Bass Rock appears on p. 107. A remarkable study is J. E. Ruxton's picture of a pair of black-throated divers sitting side by side on the nest ; the 'happy expression' on the face of one of the birds is clearly seen. H. Morrey Salmon's photograph of a pair of herons at the nest is a delicate and attractive piece of work. On p. 119 is a remarkable photograph of a swallow in flight taken by J. A. Speed, and on p. 131 Ian M. Thomson has an excellent picture of a pair of Montagu's harriers.

Finally, Hugh G. Wagstaff's skill in bird photography is seen in two outstanding photographs—one of a buzzard eating a rabbit on a hillside, the other of a pair of merlins exchanging forceful remarks at the nest.

This is one of the most interesting bird books that have been published for a long time.

Seton Gordon

THE CLINICAL ASPECT OF PREVENTIVE MEDICINE

Preventive Medicine and Public Health

By Prof. Wilson G. Smillie. Pp. xvi+607. (New York : The Macmillan Co. ; London : Macmillan and Co., Ltd., 1946.) 6 dollars ; 30*s*. net.

PREVENTIVE medicine is the offspring of clinical medicine. Thomas Sydenham re-interpreted the Hippocratic conception of epidemics and led the way to the domain of modern epidemiology. The science of preventive medicine began in the eighteenth century, through the work of medical practitioners, like Huxham, Mead, Heberden, Fothergill, Haygarth, Willis and Withering, observers of the clinical features of epidemic disease, the influences of external environment, the paths of contagion and infection, and the effects of climate and season. University education in preventive medicine was initiated in 1768 by Johann Peter Frank, director of public health in Austrian Lombardy, and his international fame led to the creation of the first chair of public health in the University of Edinburgh.

Unfortunately, the specialization of public health for a considerable time brought about a dichotomy between preventive and clinical medicine. This was partly due to the beliefs of Edwin Chadwick, a pioneer in English sanitary reform ; he held that all zymotic and other diseases were due to filth, and that clean living, improvement of water-supplies, refuse removal, and bettering the houses of the workers would bring about a reduction in the death-rate and the restriction or extinction of pestilences. These views ignored the knowledge gained by Sydenham and the epidemiologists of the eighteenth century on epidemic infection and morbid contagia. Bacteriology afterwards demonstrated that environmental hygiene, while of great value in preventing much morbidity and mortality, was not the whole explanation. The victim of the disease and the human carrier claimed attention as well as his surroundings. More recently, prevention has extended its sway into the study of sociology, eugenics, inheritance, race, nutrition and a hundred other subjects, embraced under the comprehensive term of 'social medicine', which disturb health and favour disease.

Tradition dies hard, and the instruction of medical students has not moved with the times. For many years it has properly been deemed desirable that instruction should be given in public health and preventive medicine in the medical courses of Great Britain and the United States. Yet too much attention is still devoted to details of sanitary engineering, drainage and sewage disposal. The student, with an overcrowded curriculum, is thus led to regard preventive medicine as a subject apart instead of one which should be closely integrated with his clinical studies of disease. It is satisfactory to know that a revision of undergraduate instruction in Great Britain is under consideration from this point of view.

Prof. Wilson G. Smillie's text-book has been written for medical practitioners and students to inculcate the sound doctrine that preventive medicine is an essential part of the practice of clinical medicine. It is a comprehensive treatise. The introduction gives a brief and lucid history of public health in the United States, including reference to the work of Lemuel Shattuck, a Boston bookseller, whose "Report of a General Plan for the Promotion of Public and Personal Health", published as a legislative document in 1850, became a foundation stone for public health and preventive medicine in the United States. Section VI of the book provides an admirable account of American public health administration which may be read with profit by all interested in this important aspect of social medicine. It is of interest to note that Paul Revere, immortalized in Longfellow's poem, was chairman of one of the first local boards of health, organised in Boston in 1798.

The whole field of preventive medicine is broadly surveyed, with emphasis upon the clinical aspect and the study of the individual. The material presented is based on clinical experience and illustrated by actual case-histories. Another good feature of the book is that the author gives references to articles in American medical journals, which enable the reader to extend his knowledge of special subjects. The book is not a system of preventive medicine, for the field covered is so wide that the author has had to compress his accounts of environmental hygiene communicable and other diseases, child hygiene and adult diseases and their prevention into brief compass ; and not all epidemiologists would agree with certain of his conclusions, for example, the statement made on p. 199 with reference to poliomyelitis that "there is little evidence that the patient himself is an important source of disease dissemination", a statement which seems to conflict with a footnote on the same page. The advanced student of preventive medicine must, therefore, supplement hi studies by more extensive reading, but he could hav no better introduction to the subject than Prof. Smillie's book.

Arthur MacNalty

METALS AND GASES

Controlled Atmospheres for the Heat Treatment of Metals

By Ivor Jenkins. Pp. x+532+60 plates. (London: Chapman and Hall, Ltd., 1946.) 50*s*. net.

COMPLETENESS of the field covered, with authoritative discussion of both theoretical and practical aspects of the subject, make Mr. Jenkins' volume a book which will undoubtedly become a standard work of reference. It is particularly welcome, in that it possesses the additional merit of being written throughout in a concise and interesting manner. It is probable that in many cases the practical worker will not desire to study all the theoretical background of the technique which he is employing; but the arrangement of the material is such that the more practical aspects can be separately considered. At the same time the theoretical side is dealt with in a manner which will be of real interest and value to the more academic reader, and the author's intention of bridging the gap between the practical and academic aspects of the subject is successfully achieved.

The use of special atmospheres in the heat treatment of metals has assumed greatly increased importance in recent years, but the information has been scattered, and the wide range of applications dealt with in the present volume will probably surprise many readers. On one hand, there are the various atmospheres used to prevent oxidation, carburization or decarburization of steels during heat treatment, or to avoid oxidation or selective depletion of surface layers with non-ferrous materials. The composition of such atmospheres must often be designed as a compromise, balancing the conflicting tendencies of the various equilibria over the range of treatment conditions, and making the problem much less simple than might appear at first sight. On the other side are those conditions where composition and treatment are deliberately adjusted to obtain carburization or nitriding of steels, and in these cases, factors such as depth of case and concentration gradients may become of first importance.

The complexity of treatment which may be involved is well illustrated from the description of steel carburizing technique. Thus in certain cases the material may first be treated under slightly decarburizing conditions to activate the surface, and then subjected to carburizing treatment, involving the three stages of low-temperature sooting, carburization proper, and diffusion of the carbon to give the desired concentration gradient. Finally, the material must be heated for hardening in an atmosphere such that surface decarburization does not occur. These and the many other successful applications of controlled atmospheres are discussed theoretically and practically in some three hundred pages dealing with industrial applications, while earlier sections of the book deal in detail with the generation, purification and analysis of the various types of atmosphere employed.

While there may occasionally be some difference of opinion as to the precise value or interpretation to be put upon some of the published data quoted in the more theoretical sections, the careful survey of this material which the author has included throughout the book is a most valuable feature. In view of the detailed consideration given to carburizing and nitriding treatments, it would have been interesting to have had some reference to the role of gases in metallic cementation; but otherwise the ground covered is remarkably complete.

The usefulness of a book can be considerably affected by the clarity of its presentation. In the present case, author and publishers are to be congratulated, not only on the general arrangement and typography, but also on the wealth of excellent illustrations, which are a most valuable feature of the book.

FOUNDATION OF THE JOHNS HOPKINS HOSPITAL

The Johns Hopkins Hospital and the Johns Hopkins University School of Medicine

A Chronicle. Vol. 1. Early Years, 1867–1893. By Prof. Alan M. Chesney. Pp. xviii+318+37 plates. (Baltimore, Md.: Johns Hopkins Press; London: Oxford University Press, 1943.) 18*s*. 6*d*. net.

THE reputation of the Johns Hopkins Hospital was founded upon the inspired endeavours of a few great men, and in this volume Prof. A. M. Chesney gives the story which he has unearthed from documents in the archives in the Hospital and in the University. The result is a work which will be very acceptable to all who are interested in the history of medical education. There are many strong ties between the Johns Hopkins and Great Britain—probably the greatest of which was its gift to us of William Osler, who left the Johns Hopkins in 1905 to take the regius chair at Oxford.

The year 1867 marks the foundation of both the University and the Medical School, since in that year Johns Hopkins caused to be introduced into the General Assembly of Maryland bills authorizing the formation of two corporations to found and administer these separate—though closely connected—institutions. His choice of trustees stamped Johns Hopkins as a man of great discrimination, as his scheme had shown him to be a man of wide vision. The University opened its doors in September 1876 with a "Faculty of Philosophy" consisting of six professors and their assistants. Huxley delivered the address at the opening ceremony. Almost straight away, under the direction of its enlightened president, Daniel C. Gilman, the University introduced courses in the basic sciences required by medical students. There were many unavoidable delays in the building of the Hospital, and it did not open its doors for patients until May 1889. The four luminaries who had been induced to take up the leading professional posts are portrayed in Sargent's well-known picture—William Osler (medicine), W. S. Halsted (surgery), Howard A. Kelly (gynæcology), and Welliam H. Welch (pathology). The rapidity with which these four men built up a distinguished reputation for the Hospital is well known.

Prof. Chesney's careful work gives much about the lives of these four men, but it will be valued even more for the brief lives of other giants who are less well known in Great Britain—W. S. Thayer, J. M. T. Finney, J. J. Abel, Franklin Mall, W. H. Howell, and many others. As a guide to the difficulties which beset the foundation of a new institution the work will naturally have great value. We look forward to the appearance of the remainder of this history.

E. ASHWORTH UNDERWOOD

AN ELECTRICAL HYPOTHESIS OF CENTRAL INHIBITION

By C. McC. BROOKS*

AND

PROF. J. C. ECCLES, F.R.S.

Physiology Department, University of Otago, New Zealand

AN electrical hypothesis of synaptic transmission has recently been proposed[1,2] which was based upon generally accepted data pertaining to the structural features of the synapse and to the electrical and excitatory properties of nerve and muscle. This hypothesis offered the first precise explanation of the temporal course of the excitatory events occurring during synaptic transmission. However, it gave no explanation of inhibition, which is so fundamental a counterpart of excitation in the functioning of the central nervous system. The hypothesis here formulated as an extension of the excitatory hypothesis rectifies that deficiency, and is likewise able to offer the first precise explanation of the temporal course of inhibition in terms of generally accepted structural and functional properties of neurones and of the synaptic contacts between them.

The development of such a hypothesis is the more necessary because the following carefully designed experiments have recently shown that inhibition of spinal reflexes occurs under conditions that preclude its explanation by all the theories hitherto elaborated[3,4]. The myotatic (stretch) reflex involves a single synaptic relay in the spinal cord with a synaptic delay of about 0·7–1·0 msec.[5–10] that is, centripetal impulses from a muscle entering via the dorsal roots pass directly via the reflexo-motor collaterals[11] to synapses on the motoneurones of that muscle. Inhibition of such a direct reflex pathway is produced by impulses from antagonistic muscles entering the spinal cord slightly before (0·2 msec.) or even simultaneously with the excitatory volley, that is, the central inhibitory time is no more than 1·0–1·1 msec.[3,6,12–15]. This inhibition is observed even when the respective excitatory and inhibitory pathways converge on the motoneurones from diametrically opposite directions[12]. Two arguments have been derived from this evidence. (i) The inhibition is exerted *directly* on a two-neurone arc and cannot be explained by any theory[16–20] that involves refractoriness or subnormality of interneurones or some failure of summation due to temporal discrepancy in synaptic bombardment. Furthermore, it must occur within the confines of the motor nucleus and hence be exerted either in the presynaptic terminals[14] or on the motoneurones themselves[3]. (ii) The short central inhibitory time shows that the inhibitory impulses act with no more synaptic delay than the excitatory impulses; hence it is argued that there are likewise no interneurones in the inhibitory pathway. However, it will be shown below that this latter inference is not valid.

Thus there has been a return[3] to the original concept of Sherrington[21–23], that there are converging on motoneurones two sets of impulses: those exciting and so tending to cause the reflex discharge of impulses, and those directly opposing this influence. In regard to the mechanism of this inhibitory action, there has been no theoretical advance beyond three vague suggestions: (1) that the inhibitory impulses block the excitatory impulses in the presynaptic terminals[14], presumably by some anelectrotonic action[24,25]; (2) that the inhibitory effect is exerted on the motoneurones because the inhibitory impulses terminate in some special spatial pattern on the motoneurone, for example, around the axon hillock[12,26–28]; (3) that there are specific inhibitory synapses at which presynaptic impulses exert an effect which is the functional opposite of excitation[3,12].

None of these is satisfactory. Renshaw's[14] experimental support of the first is susceptible of alternative explanation[29], and, as Lloyd[3] points out, it is difficult to conceive of impulses affecting the terminals of fibres in a motor nucleus without at the same time acting on the motoneurones. Actually such a secondary block is directly demonstrable, but only as a secondary phenomenon some milliseconds after the onset of inhibition[29]. In mammalian motoneurones there has been no demonstration[30] of any specific spatial distribution of presynaptic terminals such as occurs with Mauthner's cell[27]. Nor has there been any histological evidence of two distinct types of synapse[27,30] such as would be expected on the third suggestion. In this connexion there has been, of course, an attempt to explain inhibition as due to the liberation of an inhibitory substance antagonistic to an excitatory transmitting substance, but no evidence supports such a contention, and it now seems probable that the peripheral excitatory transmitter, acetylcholine, plays no part whatsoever in central synaptic transmission[31].

None of the above objections can be offered against the hypothesis developed here from the following assumptions, which are based on well-established properties of neurones and their synapses.

(*A*) The synaptic knobs closely investing the surfaces of the soma and dendrites of a motoneurone (and indeed of any neurone in the central nervous system) may be divided into two types which are intermingled on the surface: (i) those belonging to the long axons of neurones, including the dorsal root fibres (the reflexo-motor collaterals of Cajal); and (ii) those belonging to axons no more than 2–3 mm. in length. Following Cajal[11], the neurones with short axons will be called Golgi cells. They are now known to be numerous in the spinal cord as well as in the brain, and to be interpolated (hence the alternative names, internuncial neurone and interneurone, which, however, need not necessarily have such short axons) in most pathways between entering dorsal root fibres and motoneurones[11,32].

(*B*) The surface membrane of the soma and dendrites of a neurone has essentially the same electrical properties as the axon—see assumption *B* of the excitatory hypothesis[1,2]. For example, the soma is electrically excitable[5,33,34], and impulse propagation occurs over its surface presumably just as with the axon[34–37]. Its excitability is raised by catelectrotonus (outflowing currents) and decreased by anelectrotonus (inflowing currents)[25]. In addition, assumption *C* of the excitatory hypothesis[1,2] postulates a specialization of the immediate post-synaptic areas of the soma (and dendritic) membrane whereby they react to synaptic excitation by local responses[38] rather than by the all-or-nothing membrane breakdown characteristic of the propagated impulse. It is possible that the minute size of such post-synaptic areas is alone responsible for this specialized reaction.

---

* John Simon Guggenheim Memorial Foundation Fellow. On leave of absence from the Department of Physiology, Johns Hopkins University, Baltimore, Md.

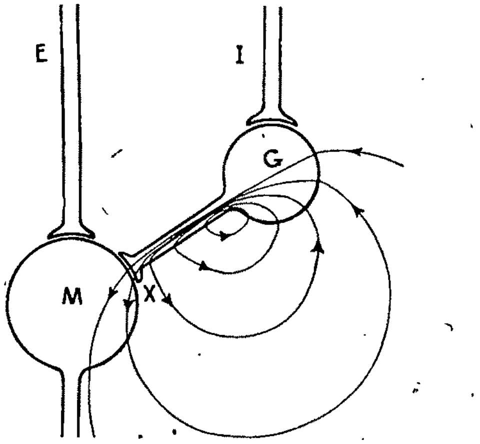

Fig. 1

(*C*) When a presynaptic impulse is propagated down to a synaptic knob on the surface of a neurone, it sets up a local response of the immediately adjacent post-synaptic membrane[1,2], which consequently is depolarized by diminution of its E.M.F. and resistance. Current flows from other areas of the neurone's surface (soma, dendrites and adjacent segments of the axon) into this relatively negative focus, thus producing the synaptic potential as recorded either by an adjacent focal (needle) electrode[34] or from the ventral roots[10,25,39]. If the synaptic potential is sufficiently large (that is, if a sufficient number of synapses is excited), the surface membrane of the neurone will be sufficiently depolarized, both intensively and extensively, to initiate the discharge of an impulse. If it is not, then after perhaps some spread of the active foci[34], the excitation dies out and the rebuilding of membrane potential gives the characteristic exponential decay of the synaptic potential.

These assumptions will now be applied in operating a schematic model (Fig. 1) of the simplest situation in which inhibition occurs. It has been shown by Lloyd[3] that the afferent fibres from a muscle excite the motoneurones of that muscle and its synergists and inhibit the motoneurones of its antagonists. The excitatory path is monosynaptic, and he has assumed from the similarity between the central excitatory and inhibitory times (each about 1 msec.) that this is also true for the inhibitory path. However, it will be shown that such similar timing is to be expected if a Golgi cell, *G*, is interpolated on the inhibitory pathway. Thus we have the excitatory reflexo-motor collateral, *E*, ending in a synaptic knob directly applied to the motoneurone, *M*, while the synaptic knob of the inhibitory fibre *I* (also a collateral of a dorsal root fibre) ends on *G*, which in turn has its knob on *M*. Many such knobs as those shown may be imagined covering the somas and proximal dendritic regions of *G* and *M* (assumption *A*).

If a volley of impulses which is being propagated to synaptic knobs of *I* fibres sets up a synaptic potential (assumption *C*) which is too weak to initiate the discharge of an impulse from *G*, current will flow as shown in the diagram during the whole temporal course of this potential; hence the axon (and inactive areas of the soma and dendrites) will act as a source for the current flowing in through the sink of the active areas. The size of the synaptic potential recorded from an emerging ventral root has shown that the axon acts as a considerable source of current even two or more millimetres from the soma[10,25,39]. With *G*, therefore, there will be, as shown, a considerable outflowing current from the synaptic knob of its axon, where the expanded area (due to branching as well as the swelling) of the highly resistant surface membrane gives favourable opportunity for current penetration. On account of the close synaptic apposition, this outflowing current will in large part penetrate the post-synaptic membrane of *M* (Fig. 1) and produce there a localized region of anelectrotonus, which will be a region of depressed excitability (assumption *B*). Of course, this penetrating current will also have to pass outwards across the surface membrane of *M*, leaving there a cathodal (excitatory) action, but such effects will be negligible in intensity because so widespread over the neurone and so much in the unstrategic areas of the dendrites. It is even possible that the *raison d'être* for the widespread dendritic branching is to provide the soma with a widely distributed surface for a dispersed return circuit through the grey matter.

Consider now the situation arising when impulses are fired simultaneously along several *E* and *I* fibres. The *E* impulses will produce local responses in the regions of *M* beneath their synaptic knobs, and, if of sufficient intensity, these responses will rapidly fuse and spread, generating the discharge of an all-or-nothing impulse (assumption *C*).

However, the *I* impulses are simultaneously producing local responses in *G* cells and so simultaneously causing anelectrotonic foci under the synaptic knobs which these *G* cells have on *M*. Thus the simultaneous *E* and *I* volleys give rise simultaneously to a mosaic of patches of local response and of anelectrotonus on *M*. The anelectrotonus suffers from the disadvantage that its rising phase will be somewhat delayed on account of its electrotonic spread from the soma of *G*, but the local responses on *M* also take a little time (usually 0·2–0·5 msec.[10]) to spread and fuse sufficiently to initiate the impulse discharge. Hence the anelectrotonic areas on *M* should just be able to exercise an appreciable depression on the spread of the local responses when the *E* and *I* volleys are simultaneous; and there should be a rapid increase in the depression as *I* is moved earlier relative to *E*, for then, as the local responses are being set up under *E* knobs, they will be presented with a well-established anelectrotonic mosaic.

According to the excitatory hypothesis[1,2], the synaptic potential generated in cell *M* by impulses in one set of *E* fibres is the cause of the facilitation of *M*'s reflex discharge in response to impulses in another set of *E* fibres[3,10]. Likewise the present inhibitory hypothesis attributes the inhibition of such a reflex discharge to the synaptic potential which impulses in *I* fibres generate in *G* cells. Hence the time courses of such facilitation and inhibition should be relatable to the synaptic potential and so to one another. This prediction receives striking confirmation from the recent determination of the time courses of the unitary excitatory[3,10] and inhibitory processes[3] set up by *single* *E* and *I* volleys uncomplicated by impulses relayed through interneurones (*E* and *I* curves of Fig. 2). It is evident that the respective hypotheses would predict the similar decaying phases observed for the two curves, for it relates both to the decay of the synaptic potential[10,34]. The differences in the early phases are also predictable. Simultaneous action of the two excitatory volleys would

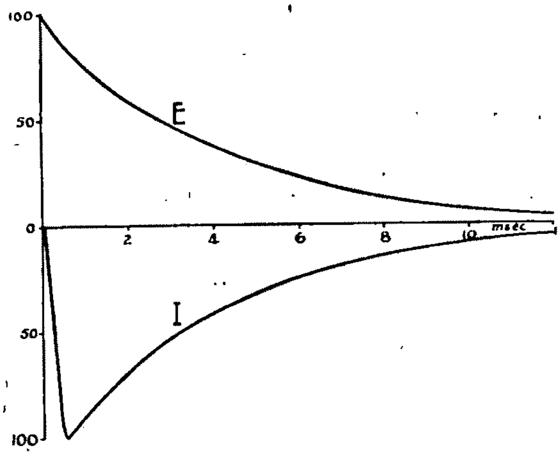

Fig. 2

give optimum conditions for summation of synaptic potentials, and hence the facilitation curve, *E*, would be expected to decay from a maximum with zero interval between the two *E* volleys[3,10]. On the other hand, we have seen that the inhibitory hypothesis predicts that the inhibitory curve, *I*, should rapidly increase from zero inhibition at about zero *I E* interval. Focal recording shows that the synaptic potential of the soma of the neurone (as distinct from that picked up from the ventral root[10]) takes about 1·0–1·5 msec. to attain its maximum[34], but the *I E* interval for optimum inhibition would be expected to be shorter than this, for the optimum would occur as soon as the developing anelectrotonic foci in *M* had an adequate start over the developing local responses of *M*. At an *I E* interval of 1–1·5 msec. the anelectrotonic foci would be fully developed when the local responses of *M* were being initiated, and would actually be decaying during the growth of these local responses; hence such an interval would be well beyond the optimum. The inhibitory hypothesis would thus predict the unitary inhibitory curve actually observed (*I* of Fig. 2) rising from zero to a maximum at about 0·5 msec. and then decaying with much the same time course as the unitary facilitation curve (*E*).

Hitherto it has been assumed that the *I* volley does not generate in *G* sufficient synaptic potential to evoke the discharge of an impulse. If this had occurred, the hypothesis would predict that the usual synaptic excitatory action would have ensued upon the arrival of the impulse at the synaptic knobs on *M*. Thus there would be an initial period of inhibition passing over to excitation about 1·0–1·5 msec. later. The additional delay would be largely spent in initiating the impulse in *G*, and in the synaptic delay involved in setting up local response under the knobs on *M* (cf. the excitatory hypothesis[1,2]). Lloyd (ref. 3, Figs. 8 and 10; ref. 4, Fig. 3) has observed precisely this transition after about 1·5 msec. from a primary inhibition to a secondary facilitation, and furthermore he finds it impossible to distinguish by threshold the afferent fibres responsible for these two effects. The slightest increase in the strength of the stimulus to the afferent nerve suffices to superimpose a secondary facilitation on a pure primary inhibition. In terms of the hypothesis, a slight increase in the *I* volley causes many *G* cells to discharge impulses, so generating the secondary facilitation of *M*. Thus the principle emerges that the synaptic knobs of a Golgi cell's axon have a pure inhibitory action or a diphasic inhibitory-excitatory action according as the synaptic potential of that cell is not, or is, adequate to evoke the discharge of an impulse.

On the other hand, at the synaptic knobs of axons more than a few millimetres in length such a situation would not arise, because no appreciable current would be generated there by synaptic potentials of the somas; and this would also obtain *a fortiori* for the dorsal root fibres, where the somas generate no synaptic potential. All such synaptic knobs would be purely excitatory. However, short collaterals arising from long axons close to the soma (the axon collaterals) would resemble the axons of *G* cells in being potential inhibitors. Hence arises a reason for the fact that the fibres of the long tracts in the spinal cord, for example, the pyramidal tract, end in synaptic relationship with Golgi cells and not directly with motoneurones[13,40,41]; for by so doing they become potential inhibitors as well as excitors of the motoneurones.

Reference to Fig. 1 reveals that according to the inhibitory hypothesis a needle electrode (insulated to the tip) close to the synaptic knobs of the *G* cells on the motoneurones, for example at *X*, would be expected to show a positive potential (relative to an indifferent electrode) having approximately the same time course as the inhibition. Positive focal potentials are indeed recorded from regions of inhibited motoneurones[14,28], but their time courses do not as a rule correspond with the inhibitory curves. In accordance with the hypothesis, blocking internuncial pathways by very deep anæsthesia shortens these positive focal potentials, so that their time course is similar to that of the negative synaptic potential[29]. However, under conditions giving unitary inhibition (hamstring afferents inhibiting quadriceps motoneurones), the focal potential may be negligible or show a very small positivity or negativity[29]. In evaluating such observations, it must be realized that, since the Golgi cells are interspersed between the motoneurones[19,32,41], their synaptic potentials may be recorded either as negativity or as positivity; for example, *X* in Fig. 1 might also be close to the somas of other *G* cells, recording their synaptic potentials as a negativity. Therefore the negligible focal potential set up by a hamstring afferent volley in quadriceps nucleus would be expected if its inhibitory action were due to the synaptic potentials that it set up in Golgi cells within that nucleus. Thus in testing the inhibitory hypothesis it will be necessary to study the spatial distribution as well as the time course of the focal potentials set up by inhibitory volleys.

The association of inhibition with a positive cord potential (recorded with leads on the surface of the spinal cord), and hence with anelectrotonus, has been widely recognized[16–18,20,42]; but in formulating theories of inhibition it has always been assumed that such potentials were homologous with the positive after-potentials of peripheral nerve, and hence always subsequent to the discharge of an impulse by a motoneurone or an interneurone. This is certainly not the case with direct inhibition, which is now known to play such an important part[3,4] that other mechanisms appear of but secondary importance. The production of anelectrotonus by the mechanism illustrated in Fig. 1 is the first attempt to give a coherent account of the mechanism of this direct inhibition'.

An argument against the present anelectrotonic hypothesis of inhibition is that during inhibition of motoneurones no positivity is detectable by ventral root recording[25], that is, on the axon of *M*, which on the contrary shows a large negative potential during the subliminal excitation of motoneurones[10,26,39]. However, the situations are not comparable, for with excitation the current will be flowing into the activated areas from other areas, including the proximal regions of the axon; whereas with inhibition the current generating the anelectrotonus will be flowing inward under the synaptic knobs and outward at other areas (Fig. 1). Thus the current flow in the ventral root will be just the same as with excitation, and hence during inhibition the ventral root potential should be in the same direction as with excitation despite the diametrically opposite effect on the soma. However, since it is generated extrinsically to the motoneurone, it would be much smaller than the synaptic potential.

The large 'stretch' afferents of a muscle excite that muscle and its synergists by a monosynaptic pathway and 'directly' inhibit its antagonists[3,4]. According to the inhibitory hypothesis, Fig. 3 gives the pathway for this reciprocal relationship between the flexors and extensors of a joint (the knee; *Q* quadriceps; *H* hamstrings) which we may regard as the simplest co-ordinative act of the central nervous system (cf. the classical figure of Sherrington[43]). The flexor and extensor 'reflexo-motor' collaterals end at synaptic knobs on the respective flexor and extensor motoneurones (*M*) and also give off collaterals[11] to Golgi cells (*G*), the synaptic knobs of which are reciprocally distributed to the extensor and flexor motoneurones respectively. Fig. 1 gives the key to the operation of Fig. 3 as a model of reciprocal innervation.

These illustrations suffice to show that the present hypothesis offers a precise and simple explanation of some inhibitory phenomena. Its performance is just as impressive in relationship to all other experimental observations that we have found in the literature. In particular, it should be noted that according to the hypothesis, inhibition is not a threshold phenomenon. All gradations of intensity can exist in the respective anelectrotonic and catelectrotonic areas of the mosaic on a soma, and the initiation of an impulse virtually will be dependent on their algebraic summation, much as was postulated for the excitatory and inhibitory states, C.E.S. and C.I.S.[21–23]. Thus the excitatory and inhibitory hypotheses may be regarded as developments from these original concepts, which so adequately fitted the literature up to that time.

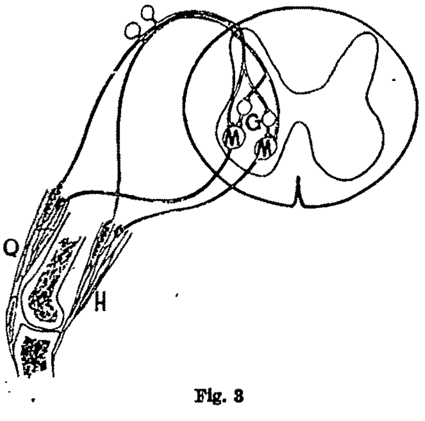

Fig. 3

The concept of the subliminal fringe has been fruitful in its application to reflex phenomena[23,44,45], but the present hypothesis gives new potentiality to it. Hitherto it has regarded the subliminally excited neurones (the subliminal fringe) as a transitional group available for facilitation. Now we postulate that the Golgi cells of the subliminal fringe are, in addition, acting as inhibitors of the neurones next in series. Thus with the exception of the monosynaptic reflexes, an inhibitory surround will encircle the active focus of a reflex; hence arises a ready explanation of simultaneous contrast, which is of such importance in the neural mechanisms of conditioned reflexes and of vision. In this latter connexion it is further to be noted that an inhibitory action of the retina is associated with a prolonged potential of opposite sign to the excitatory potential[46], and that there are many neurones of the Golgi cell types in the retina, for example, the bipolar and amacrine cells. The inhibitory function of the subliminal fringe may also provide the basis for an explanation of rhythmic reflexes, which hitherto have been so poorly understood[23].

The most interesting feature of the present inhibitory hypothesis is the dual role it gives to the Golgi cells. Undoubtedly these cells often act as excitatory links in reflex pathways which may eventually exert excitatory or inhibitory actions on motoneurones. Hence arises the familiar 'delay path' explanation of prolonged excitatory or inhibitory action[19,23,35]. Others may normally never be sufficiently excited to discharge impulses, and hence always function as inhibitors. But some would appear to function as inhibitors or excitors according to the degree of their own excitation; and, of course, any such Golgi cell in a chain would be able to act as an inhibitor of the Golgi cells next in series. Now Golgi cells arranged in the most intricate cross-linked chains form the outstanding feature of the structure of the higher centres of the brain[32,47]; hence the hypothesis that such cells are responsible for inhibition and may be either excitatory or inhibitory according to circumstances leads to the most interesting speculations. For example, in normal cerebral activity there is believed to be continual rhythmic discharges of cells with impulses circulating around neurone chains of unimaginable complexity. According to the hypothesis, we must assume in the normal waking state a delicate poise of Golgi cell activity giving a balance of excitatory and inhibitory action. If now any depression of cortical activity is brought about, the lowered excitation in the Golgi cells would cause the reversal of many from excitors to inhibitors, and hence deepen the depression; and conversely, raised excitation would convert inhibitors to excitors. Such reactions would seem to provide a clue to the understanding not only of the subtlety of reactions of the cerebral cortex, but also of its very great sensitivity both to narcotics and to convulsants. For example, narcotics not only would depress the excitation, but would thereby augment the inhibition. Likewise lowered cortical activity due to deprivation of most incoming sensory impulses would convert excitatory Golgi cells to inhibitors, so bringing about the widespread cortical inhibition that we know as sleep. Of course, a continued inhibition would be dependent on some continued cortical activity; hence active inhibition in the early stages of sleep would be expected to give place to mere inactivity. This parallels the observation that sleep lightens an hour or so after its onset[48]. Such examples illustrate how the hypothesis may be of value in understanding the functioning of the higher parts of the central nervous system.

THE ROYAL ACADEMY, 1947

By Dr. A. TINDELL HOPWOOD

THERE are those who exhibit at the Royal Academy, and those who do not: there are those who visit the Royal Academy, and those who do not. Once the doors of the Summer Exhibition are opened, those who do either are of present importance and mutually dependent. The interplay of artist and visitor makes each new show a fresh adventure for anyone who is neither too ignorant to have acquired that sense nor so bored as to have lost it. Ignorant may seem a harsh word to use, but it is not unkindly meant. One cannot find intellectual adventure in that which one does not understand, but there is adventure in the effort necessary to understanding. For most people the annual adventure of the Academy consists in making the effort to understand. None but a favoured few can hope to escape the necessity of effort, since there are very few who can easily understand what an artist is striving to achieve. According to Michelangelo, "Good painting is a music and a melody which only the intellect can appreciate, and that with great difficulty". The same sentiment has been repeated by successive generations of artists, among others by the Academy's first president. This, if it be true—and there can be no argument about that—makes nonsense of the claim that 'art belongs to the people' taken in its usual connotation. On the other hand, it is true that art belongs to so many of the people as are willing to make the intellectual effort necessary for its comprehension. In art, as in all other human activities, one cannot have something for nothing.

Out of nothing, nothing is made, is just as true of artists as of spectators. The latter reveal the vacant mind by their chatter, the former reveal it in their works. Every year such minds are with us, but the Hanging Committee can usually find spots where their patients may linger in comparative obscurity. Perhaps it is unfair to introduce in this way an exhibition which is so much better than its predecessor, but I do not think it is. The higher the general standard, the more obvious do the babblers become; but it is also easier to close one's ears to their babble.

For the past fifty years there has been much noisy argument about the modern movement in art, and the modernists have shown a degree of intolerance equalled only by the intolerance of their opponents. The point at issue really boils down to whether line or colour is pre-eminent. The question is of small significance because each artist and each spectator will return that answer which best accords with his own temperament. There is no merit in denying the artistic worth of "Bol de Lait" by the late Pierre Bonnard, neither is there merit in praising it to the detriment of more academic canvases. Bonnard was a colourist and light was necessarily his primary interest. Now it is a curious thing that light, which reveals to us the planes and perspectives and all the geometry of Nature, ends by obscuring what it reveals. Turner knew this in his day, and M. Bonnard's picture is a restatement in a different idiom.

It is fitting that works by a great Frenchman should hang in the Academy, for it is from France that the moderns draw their inspiration; but one should not forget that the French themselves derive from an Englishman, John Constable, whose strivings after light were no less intense than those of Cézanne. Moreover, the inspiration from across the Channel must not blind us to the native interpretation of Constable's teaching. For this reason attention should be given to Sir Alfred Munnings' "Frisian Bull", in which the landscape suggests that his oft-expressed affection for George Stubbs is equalled by his affection for Constable. "Sketch of a Newmarket Start", which hangs a few feet from the bull, is full of a nervous vitality vastly different from the bucolic peace of the latter, and this tends to obscure the masterly skill with which the rhythmic motion of the jockeys and their mounts is conveyed.

One of the less good positions is No. 1. It is on a reverse wall, but has the compensation that most visitors look there when they are fresh, and before their energies have begun to flag. Here hangs "Once Upon a Time" by Lilian Jelly, noteworthy for its interpretation of texture and line. On the same wall, "Autumn", by Dame Laura Knight, is the first of three valiant and not unsuccessful attempts at rendering atmospheric effects of great difficulty.

The same room contains several pictures by younger artists, two of whom appear for the first time: "A Yellow Dressing Table" is by Pat Newton, and "Still Life" by Henry Kilvert. There are also three flower pieces, "Autumn Flowers", by Elsie Atkins, who exhibited in 1944 and 1946; "Summer Flowers", by Vera Waddington, also an exhibitor in 1944 and 1946; and "Geraniums", by D. Travers-Smith, whose picture last year was, I think, her first. Both Miss Atkins and Miss Waddington paint flowers well, and each has shown in previous years that she is not afraid of other subjects. The arrangement of Miss Travers-Smith's geranium is rather obvious, and the design is over-emphasized by the background. Best of all is the yellow dressing-table in its garret window; there is more originality in the subject, and more character in the painting.

One of Mr. Churchill's pictures hangs near the dressing-table. It is "Winter Sunshine", a not altogether successful sketch of a red-brick house standing in a snowy garden. The arrangement of the high lights, and the mass of shadow in the middle of the canvas, give the impression that the centre of the picture has dropped out. His other picture, said to be a later work, is in Gallery III. "The Loup River, Alpes Maritimes" is above the average in its rendering of flowing water. Taken together, they show Mr. Churchill to have considerable talent as a painter, but they display none of that robustiousness popularly associated with Mr. Churchill the politician.

If the Academy were restricted to oils, one might well stop there, for what has been said serves as a sample of the whole. As it is, there are other media to consider, and of them the water-colours in the South Rooms are easily the most important. Water-colour drawing is so essentially an English art that one is not surprised when its practitioners prove to be more consistently interesting than the painters in oils. R. Vivian Pitchforth, Barbara Jones, Hadley Rowe and Peter Lowry each has something worth saying, though Mr. Rowe should know better than to put tropical shells on what appears to be a typically English beach. Mr. Pitchforth is, of course, one of our leading water-colourists and an associate of the Academy, but Miss Jones and Mr. Rowe are, I believe, exhibiting for the first time. There is both character and individuality in their work. Mr. Lowry had pictures hung in 1945 and again last year; that he tends to dramatize his subject is not necessarily a fault. Two pictures of the shipyards at Appledore possess a maturity and sureness of touch which prove Michael Leszczyński to be much more than a beginner, even though this is the first time he has been hung in the Academy. Hal Yates' "Runswick" and Dennis James' "Snow Scene, Kingsley Way" each deserve more than a passing glance; the latter is not hung as well as it should be.

To return to the oil-paintings. Henry Hoyland has been represented by a picture or two since 1944, and, as his two studies of the circus show, he improves each year. Jean Primrose has two works of great promise in "Ballerina" and "Angela Reading", and that brings us to the Black and White Room (Gallery IX). This I found dull apart from Miss Winifred Austen's bird studies, which have a charm all their own, and Robert Austin's engravings. Sir Lionel Lindsay's dry-point is of particular interest: it throws a flood of light on his book "Addled Art".

There is little to be said about the architectural exhibits; present conditions are not kind, and architects are in partial eclipse. Neither is the sculpture very interesting. It is always difficult to make a gallery of small busts look anything but spotty, and this year the difficulties appear to have proved greater than usual.

Nevertheless, this is a 'good' Academy, and if the next can improve on it as much as this one has improved on last year's, then there will be firm reason for thinking that artists as a whole have recovered from their post-war malaise.

THE ADRENAL CORTEX

THE fourth meeting of the Society of Endocrinology, held on March 28 in the Department of Anatomy, University of Birmingham, was devoted to a discussion on the adrenal cortex. In the opening paper, entitled "Recent Advances in the Chemistry of the Adrenal Cortex", Dr. C. W. Shoppee mentioned briefly the six steroids newly isolated from adrenal tissue during the past seven years, which include œstrone, Δ^4-androstene-3 : 17 dione, and 17-hydroxyprogesterone. The total number of adrenal steroids with known structures is now twenty-eight, of which six are active in preserving the life of the adrenalectomized animal. The structures of most of these compounds are completely determined. Where hydroxyl groups exist at positions 3 and 11 they are (β) orientated, while hydroxyl groups at position 17 are almost certainly in the (α) position. During the past few years it has become clear that adrenal steroids, as well as deoxycholic acid, have the side-chain at position 17 in the (β) position and not, as was previously believed, (α) orientated. Reichstein has now prepared all six physiologically active steroids artificially. The molecular features essential for high activity appear to be a 3-keto-Δ^4-grouping, together with a 17 (β) side-chain of the form $-CO.CH_2OH$. For activity with respect to carbohydrate and protein metabolism, an oxygen atom at C_{11}, either as a keto-group or a (β)-orientated hydroxyl group, appears to be essential.

The pure crystalline substances isolated from cortical extracts represent only a small fraction of the activity of the concentrates from which they are prepared: the greater part of the activity (about 90 per cent) remains in the so-called amorphous fraction. The latter shows somewhat anomalous physiological properties, and it is likely that there remain to be isolated one or more unknown labile compounds, probably containing five oxygen atoms, which are more active than any of the hormones yet obtained in a state of purity. Lowenstein and Zwemer (*Endocrinology*, 39, 63; 1946) have recently reported the isolation of 11-dehydrocorticosterone and two incompletely characterized substances, the combined activity of which equalled 80 per cent of the activity of the original concentrate. One of these compounds gave ascorbic acid by mild anaerobic hydrolysis; the other, presumably steroid, product of hydrolysis has not been isolated.

In his communication entitled "The Pituitary–Adrenal Relationship", Dr. M. Reiss discussed first the problem of the isolation and biological assay of pituitary corticotrophic fractions. For assay purposes, Dr. Reiss and his colleagues have investigated the histological changes occurring in the adrenal glands of hypophysectomized rats. The sudanophilic substances between the zona glomerulosa and the zona fasciculata were found to disappear seven to ten days after hypophysectomy, the wide so-called sudanophobic zone thus formed being an enlargement of a very thin zone normally present in young rats. This zone is abolished by treatment of the hypophysectomized rat with corticotrophic extract, and a standardization of the extract is based on these histological changes. Workers in two different laboratories (those of H. M. Evans and of C. N. H. Long) have isolated, by different procedures, the same pure substance which they claim to be the corticotrophic hormone. This does not exclude the possible existence of more than one corticotrophic substance; and indeed when one considers the multitude of active substances produced by the adrenal cortex, the existence of different corticotrophic substances responsible for the mobilization of these adrenal steroids is by no means impossible. The influence of the known corticotrophic substance on the adrenal cortex is complex. The cholesterol content falls in the first three hours (rat) and later rises. A fall of ascorbic acid content is detectable an hour after corticotrophic treatment, and the fall is proportional to the dose given. By direct estimation the hormone content of the adrenal gland was found to be increased 24 hr. after treatment, but substantially reduced 48 hr. after (Hempill and Reiss, unpublished). The changes in the hormone activity of the blood were opposite to those of the adrenal tissue.

Although adrenal function is considerably diminished after hypophysectomy, there is no reason to believe that adrenal-cortical activity ceases in the absence of pituitary corticotrophin; the hypophysectomized rat can survive the avulsion a year or more, but it would die in the course of a few days if all the cortical tissue had been removed. Little is known about the nervous control of the pituitary anterior lobe production of corticotrophin, though it appears probable that the secretion of corticotrophin is influenced by a psychic factor. Although the physiological effects of corticotrophin are mainly to be ascribed to stimulation of the secretory activity of the adrenal cortex, it would not be surprising if some actions of corticotrophic extracts failed to agree with those of known adrenal steroids. It is probable that adrenal steroids remain to be isolated, while it is yet uncertain if all those isolated are of physiological significance.

In his survey of the "Adrenal Cortex and Metabolism (including Electrolyte Metabolism)", Prof. F. G. Young pointed out that at present no simple comprehensive theory seems able to explain the diverse actions of adrenal steroids, and as more experimental evidence becomes available the earlier generalizations seem less and less certain. It is important not to neglect the fact that when one injected a hormone one was studying not merely the effect of the hormone on the animal but also the interaction of the animal and the hormone. Changes in food intake, adaptation to newly imposed experimental procedures particularly in long-term procedures, metabolic interconversions of administered steroid substances, all could and probably do complicate the interpretation of apparently simple experiments. In particular, the control of food intake by paired-feeding control experiments is of the greatest importance. Conway and Hingerty (*Biochem. J.*, **40**, 561; 1946) have shown that the potassium ion content of the muscles of the adrenalectomized rat is raised. This controverts the idea that the increased blood potassium is to be ascribed to leakage of potassium ions from the tissue cells. These authors have also shown a striking increase in plasma and muscle magnesium ion content, possibly significant to the muscular asthenia of adrenal insufficiency. The influences of adrenalectomy on carbohydrate and protein metabolism can be largely prevented by adequate therapy with sodium chloride, although such treatment does not prevent the catastrophic fall in carbohydrate storage which results from a short period of starvation in the adrenalectomized rat. Since deoxycorticosterone and the amorphous fraction of adrenal extracts both possess striking activity in inducing retention of sodium chloride in the normal and adrenalectomized animal, it is perhaps surprising that these adrenal fractions have so little action on carbohydrate and protein metabolism. Moreover, an important *in vitro* action of adrenal extract on hexokinase activity has been traced to the amorphous fraction.

Cori *et al.* (*J. Biol. Chem.*, **160**, 633; 1945: *Fed. Proc.*, **5**, 150; 1946) have shown that the activity of hexokinase in catalysing the transfer of a phosphate group from adenosinetriphosphate to glucose, forming glucose-6-phosphate, is diminished *in vitro* by the addition of anterior pituitary extract, and that this pituitary inhibition can be emphasized and extended by the addition of adrenal extract, though the latter alone has no obvious action in this respect. The influence *in vivo* of adrenal extract on other enzyme systems (for example, arginase, phosphatase, cytochrome oxidase) has opened up new lines of investigation of the greatest significance. It seems possible that the adrenal hormones, like enzymes, are not essential for the mechanisms of the body, but hasten or retard reactions which will proceed in the absence of the hormones.

In discussing "The Adrenal Cortex in Shock and Stress", Dr. G. Ungar pointed out that there is good experimental evidence for three main conclusions: (1) adrenalectomized animals exhibit a lowered resistance to many different types of noxious stimuli; (2) the adrenal glands show morphological changes after exposure to these stimuli; (3) the administration of adrenal steroids can, in some instances, enhance the resistance of adrenalectomized animals to these stimuli. It has long been known that stimuli can sometimes induce in animals a temporary increase in resistance to the same and non-related stimuli. Selye has proposed the term 'adaptation syndrome' in this connexion, and divides this syndrome into three stages: the alarm reaction, the adaptation phase, and the exhaustion phase. Most of the symptoms of the adaptation phase cannot be induced in adrenalectomized animals, though the secretory activity of the adrenal cortex is not the only factor concerned. The influence of adrenal steroids on carbohydrate and protein metabolism, and on the involution of the thymus and lymphatic tissue generally, are of importance, but, as Dr. Ungar himself has shown, the spleen is also concerned. Noxious stimuli cause shortening of bleeding time, increase in capillary resistance, and reduction of capillary permeability. All these effects are prevented by hypophysectomy, or adrenalectomy, or splenectomy, and can be reproduced in appropriate circumstances by corticotrophin, whole adrenal extract and suitable spleen extract.

A substance which can account quantitatively for the action of cortical extracts is a recently isolated adrenal steroid, Δ^4-pregnene-3-one-17(β) : 20β : 21-triol. The active splenic substance has been obtained in very pure form, and its chemical identification is being carried out by Prof. E. L. Hirst in Manchester. During adaptation there is a reduction in the amount of histamine that can be liberated from blood cells. Histamine is liberated through the action of a proteolytic enzyme normally held in check by an inhibitor; in certain pathological conditions the enzyme is set free and is then able to split off histamine from some protein substrate. It is possible that the adrenal cortex can inhibit the liberation of the proteolytic enzyme.

In her consideration of the rate of secretion of the mammalian suprarenal cortex, Dr. Marthe Vogt first discussed the different methods available for the biological assay of adrenal cortical hormones. Most of the information on the amounts of cortical hormones present in body fluids has been obtained with methods involving the deposition of glycogen in the livers of fasting normal rats, or involving the protection of adrenalectomized rats against the effects of a low environmental temperature (Selye and Schenker assay). Dr. Vogt has successfully applied the second of these methods to the estimation of hormone activity in the suprarenal blood of experimental animals. The results were expressed, by comparison with commercial extracts prepared from slaughter-house adrenal glands, in terms of the amounts of slaughter-house material required for the preparation of crude extract sufficient to give the observed physiological activity. On this basis the normal output of adrenal hormones in a 10-kgm. dog is 720 gm./hr., which is approximately equivalent to 54 mgm./day of 17-hydroxy-11-dehydrocorticosterone.

These results confirm the idea that the hormones are not stored in the gland in the active form to any appreciable extent, but are produced from an inactive precursor and immediately released into the circulation. Furthermore, since arterial or heart blood contains no significant activity, it appears that the secreted steroids are rapidly inactivated in the tissues. The rate of hormone secretion is greatly increased by stimulation of the splanchnic nerves, and since this effect can be duplicated by the intravenous infusion of adrenaline, it appears to be an indirect one via the adrenal medulla. It has been found possible to assay the adrenal steroids liberated in the isolated perfused adrenal gland. In such a perfused preparation a prolonged increase in the rate of secretion can be induced by the addition of corticotrophin to the circulating blood. In the absence of any such added stimuli, the isolated glands have been found to secrete continuously at a steady rate which lies within the limits observed in the experiments on the whole animal. Experiments of this type are obviously of great value, since the conditions are much more experimentally controllable than those in experiments on the intact animal.

In the course of his summing-up of the discussion, the chairman (Prof. S. Zuckerman) pointed out the paradox that although extra dietary sodium chloride will maintain an adrenalectomized animal in good health under controlled environmental conditions, the secretory activity of the adrenal glands is normally surprisingly high and can rise to very high levels under the influence of environmental stimuli. What is the importance to the body of this normal secretory activity of the adrenal glands, and what is the fate of the secreted steroids ? Although the adrenal secretion may not be essential for survival under some conditions, and does not necessarily initiate reactions in the body but hastens or retards enzymically controlled processes, it is important not to under-estimate the importance of adrenal hormones, particularly under conditions of stress. The present multiplicity of apparently unrelated experimental data does not yet allow any simple generalization about the function of adrenal hormones in general; but the importance of correlating observations which can accurately be correlated in a limited way should not be neglected.

OBITUARIES

Dr. S. Monckton Copeman, F.R.S.

SYDNEY ARTHUR MONCKTON COPEMAN, the eldest son of the Rev. Canon A. C. Copeman, was born at Norwich on February 21, 1862, and was educated at King Edward VI School, Norwich, and at Corpus Christi College, Cambridge. After obtaining a second class in the Natural Sciences Tripos in 1882, he went to St. Thomas's Hospital and took the M.B. Cambridge in 1886. He proceeded to the M.D. in 1890 and was elected F.R.C.P. in 1899. For a short time he was assistant lecturer on physiology and morbid histology at St. Thomas's. In 1891 he became a medical inspector of the Local Government Board, and all his active medical life was spent in the service of that Department and, afterwards, as a medical officer of the Ministry of Health. In the same year he was one of the founders of the Medical Research Club.

Medical research early engaged Copeman's attention, and among his early papers was one on the specific gravity of the blood in disease and another on hæmatoporphyrin in urine. It is, however, by his work on variola and vaccinia that he established his scientific reputation.

The early experiments of Ceely (1839–40), of Badcock (1840) and of Klein (1892) had demonstrated that typical vaccinia may be produced in the calf by the inoculation of variolous matter. In 1892 Copeman showed that it was possible to inoculate calves with variolous lymph taken from a girl suffering from smallpox, that the inoculated calves showed vesiculation, that the results obtained became greatly modified in the course of successive removes, and further, that animals which had been thus treated were no longer susceptible to vaccination. In the same year he proved that rhesus monkeys are susceptible not only to vaccination but also to smallpox. He next investigated the degree of protection against smallpox afforded in the monkey by previous vaccination and the protection against vaccination afforded by variolation; and went on to compare the effect produced by the use of human and of calf vaccine respectively. By passing smallpox virus through monkeys and then vaccinating calves from the monkeys, he produced typical vaccinia, which gave excellent strains of vaccine lymph.

In 1865 a Commission, appointed by the Society of Medical Sciences at Lyons, having Chauveau at its head, had reported to the effect that cowpox and smallpox were dual diseases. Copeman's work supported the view that cowpox and horsepox are variola modified by transmission, or, as he phrased it: "Smallpox and vaccinia are both of them descended from a common stock—from an ancestor, for instance —which resembled vaccinia far more than it resembled smallpox".

In 1891, at the International Congress of Hygiene, Copeman described his technique for the bacteriological purification and preservation of vaccine lymph by the admixture of glycerin. This, as he observed, was no new device, but he was the first to demonstrate the selective action of glycerin in eliminating extraneous organisms from the lymph without affecting the specific virus. Later, with F. R. Blaxall, he showed that glycerin is superior to soft paraffin and lanolin in inhibiting the growth of these micro-organisms.

With Dr. Gustav Mann, Copeman collaborated in a study of the histology of vaccinia and investigated other aspects of variola and vaccinia.

As a result of Copeman's work, 'arm-to-arm' vaccination with its attendant risks was abolished, and vaccination was made a much safer and simpler operation. His work was generally adopted by the Royal Commission on Vaccination.

Copeman's discoveries are chiefly recorded in the *Proceedings of the Royal Society*, the annual reports of the Medical Officer of the Local Government Board, and in his Milroy Lectures under the title of "The Natural History of Vaccinia" (1898). He was elected a fellow of the Royal Society in 1903. He received many distinctions; for example, the Buchanan Gold Medal of the Royal Society in 1902; the Cameron Prize of the University of Edinburgh in 1899, and the Fothergill Gold Medal of the Medical Society of London in the same year; and the Jenner Medal of the Royal Society of Medicine (1925) and the Gold Medal of the International Faculty of Sciences (1938).

Although Copeman was employed in numerous administrative inquiries for the Central Health Department both at home and abroad, acted as Government delegate and served on many departmental committees, his real interest lay in scientific research, and his alert mind, fertile in new ideas, was directed to various subjects of investigation. During his later years at the Ministry of Health, he paid special attention to the problem of cancer, and his report with Prof. Major Greenwood on "Diet and Cancer with special reference to the Incidence of Cancer upon Members of certain Religious Orders" opened a new field of inquiry. In 1928, at the International Cancer Congress held in London, he read a paper on irradiated fluorescein in the treatment of cancer. He was a member of the Ministry of Health's Departmental Committee on Cancer, where his advice and ripe experience proved of much value. He was also a pioneer in immunization against diphtheria in Great Britain. During the First World War, Copeman was in charge of the Hygiene Department of the Royal Army Medical College, and helped with others to improve preventive medicine in the field. Endowed with untiring energy and enthusiasm, he took an active part in many medical societies and organisations. He was a keen naturalist and biologist and, as a member of the council of the Zoological Society, did much to develop its work on scientific lines.

On his official retirement in 1925, Copeman interested himself in local government as a member of the London County Council and chairman of the Public Health Committee of the Hampstead Borough Council. He died on April 11, at the age of eighty-five. To the end he kept himself informed of modern progress in medical research. He had a distinguished appearance and a generous and kindly disposition. A man of wide culture, he was a delightful companion. Copeman did much to maintain the high standard of English State medicine. A. S. MacNalty

Prof. W. L. Valentine

Willard Lee Valentine, editor of *Science* since January 1, 1946, died at his home in Alexandria, Virginia, on April 5. Sudden heart failure ended his career at the age of forty-two. He is survived by his wife, Norma Lawrence Valentine, and two children, Richard and Virginia.

Dr. Valentine was born in Chillicothe, Ohio, on December 2, 1904. He received the A.B. degree at Ohio Wesleyan University in 1925 and the Ph.D. at Ohio State University in 1929. During his years of graduate study, he served as assistant in mathematics and psychology, and later as instructor at Ohio Wesleyan and as instructor in psychology at Ohio State Universities.

Upon receiving his Ph.D. degree, he became a member of the Psychology Department at Ohio State University, first as assistant professor and later as associate professor. His duties there during 1929–40 were principally the direction and co-ordination of the work of the numerous instructors who gave the introductory courses in psychology. His strong interest in improving the teaching given to elementary psychology students led him during these years to write a manual of psychological experiments and to edit several collections of readings in psychology. His work during these years gave many students more interesting, and more experimental, courses than were often taught formerly.

In 1940 Dr. Valentine moved to Northwestern University in Evanston, Illinois, where he served as professor of psychology and chairman of the department until 1945.

From 1937 until his death he was treasurer of the American Psychological Association. During 1938–45 he served as business manager of the Association's publications. His careful supervision strengthened the journals financially, increased their number, and made them available to a steadily increasing group of subscribers.

His editorial skill and his experience with psychological publications led to his appointment as editor of *Science* when that journal came under the editorial direction of the American Association for the Advancement of Science. From the autumn of 1945, when he began planning his first issue, until his death, he devoted himself to making *Science* a news magazine of interest to workers in all fields of science. The format was improved and the scope of articles broadened. Material of general interest to all men of science, such as discussions of the Science Foundation bills being debated by Congress, became, under his editorship, a prominent feature of the journal.

His untimely death has ended a life of service to psychologists and scientific workers in other fields, just as Dr. Valentine was reaching his prime.

Dael L. Wolfle

Mr. C. W. Hobley, C.M.G.

Charles William Hobley died at his residence at Oxted, Surrey, on March 31 in his eightieth year. For the past six years or so his health had been frail and his activity was considerably reduced. He will be best remembered for his pioneer work for the prevention of the threatened extermination of some of the more graceful mammals. He was also an authority on the life, both human and wild, of East Africa.

Born in 1867, the son of William Hobley, of Chilvers Coton, near Nuneaton, Warwickshire, Hobley was educated at Mason College (now part of the University of Birmingham), specializing in geology. In 1890 he was appointed to a post as geologist in the service of the Imperial British East Africa Company, and as the result spent the whole of his official life in East Africa. When the region was taken over by the Government and became the East Africa Protectorate, Hobley was transferred to the administrative side, being appointed a sub-commissioner in 1894, and as time went on was allotted posts of ever greater responsibility. He was acting deputy commissioner from 1903 until 1904 and again from 1906 until 1907, acting commissioner in 1904, and acting senior commissioner in 1907. In 1912 he was placed in charge of the Seyidieh Province, and during 1912–20 he was an official member of the Legislative Council of the East Africa Protectorate as well as Commissioner of Mines. Upon the outbreak of the First World War, Hobley was appointed chief political officer to the British Expeditionary Force in East Africa, his services receiving mention in dispatches. He retired from the Colonial Service in 1921. He had been awarded the C.M.G. in 1904. An important valley on the east side of Mount Kenya was named after him.

All his life Hobley retained a keen interest in Nature, especially in East Africa, where he varied his official duties by making several extensive and important collections for the British Museum. He belonged to the Royal Anthropological Institute, the Royal Geographical Society, and the Geological Society, and served on the councils of the first two in 1931 and of the third in 1930; he was also a corresponding fellow of the Zoological Society. In 1930 he became a member of the Advisory Board of the Geological Survey of Great Britain. His greatest services were, however, rendered to the movement to provide protection for animal species which otherwise, owing to ruthless commercial exploitation, would seriously diminish in numbers. In 1923 he was appointed secretary of the Society for the Preservation of the Fauna of the Empire, and held the post for thirteen years, until in 1936 health reasons compelled him to take life more easily. In 1931 he represented the Society at the Second International Conference for the Protection of Nature held at Paris. It may be recalled that as an immediate consequence of this Congress a conference of the African Powers was held in London in 1933, which produced the Convention for the Protection of the Fauna and Flora of Africa now in force. His services to the Society were recognized by his election as vice-president.

Hobley married the daughter of the late Thomas Turner, of Sutton Coldfield, in 1905; she died in 1940. The son and daughter of the marriage survive.

G. F. HERBERT SMITH

Prof. Paul Reiss

PAUL REISS, *professeur agrégé* in the Faculty of Medicine at Strasbourg, was killed at St. Just (Cantal) on June 22, 1944, when helping to evacuate wounded members of the *Maquis*. He was forty-three years old. Reiss was born at Strasbourg. He was both personally attractive and one of the more brilliant of the younger French biologists. He was a pupil of Fred Vlès. His early work was on the relation of pH and rH to the physico-chemical equilibria in cells, from which he went on to enzyme studies, and thence to cancer work. He is buried in the crypt of the Sorbonne with others who fell in the Resistance Movement.

H. MUNRO FOX

WE regret to announce the following deaths:

Dr. Leopold Portheim, formerly director of the Biological Research Institute of the Academy of Science in Vienna, on May 21, in London.

Prof. W. Rogowski, professor of electrotechnics at the Technical Highschool, Aachen, well known before the War for his electrotechnical work.

NEWS and VIEWS

Research in Mechanical Engineering

THE Government, through the Department of Scientific and Industrial Research, is setting up a special organisation to carry out scientific research in mechanical engineering to meet and, still more, to anticipate, the needs of industry and Government departments. The eventual annual expenditure will be in the region of £250,000–£350,000, although it is unlikely that this figure can be reached for some years because of the present difficulties in obtaining suitably qualified staff and buildings. The activities of the new body are intended mainly to supplement the research carried on in other research organisations in Great Britain, and will largely be confined to those fundamental problems which underlie all mechanical engineering. Thus the subjects in which research is expected to be carried out are: (*a*) properties and strength of materials; (*b*) mechanics of solids, stress, stability and vibration of structures; (*c*) mechanics of fluids; aerodynamics, gas dynamics and hydraulics in their mechanical engineering applications; (*d*) lubrication, wear and mechanical engineering aspects of corrosion; (*e*) mechanisms, engineering metrology, and noise control; (*f*) mechanics of formation of materials; machine shaping of materials; (*g*) heat transfer, heat exchange apparatus and applied thermodynamics. The location of the research station has not yet been decided. For the time being much of the work will be carried out at the National Physical Laboratory, while other work will be arranged for at universities and other institutions. It is clear that the new station will have to work in the closest liaison with the N.P.L., which has a long tradition, in its Engineering Division, of engineering research of high quality, and which will provide the nucleus, in due course, of the new organisation. Unfortunately no land is available close at hand for the building of the new station, which will require a considerable area.

Dr. G. A. Hankins, superintendent of the Engineering Division of the National Physical Laboratory, has been appointed director of mechanical engineering research. As with all other research organisations in the Department of Scientific and Industrial Research, the director will be advised by a board, the members of which will serve in their personal capacity and not as representatives of any organisation to which they may belong. The composition of the Mechanical Engineering Research Board is as follows: Dr. H. L. Guy (*chairman*); Mr. L. Akehurst, operative, London Passenger Transport Board; Prof. R. N. Arnold, professor of engineering, University of

Edinburgh; Dr. S. F. Dorey, chief engineer surveyor, Lloyd's Register of Shipping; Sir Claude Gibb, of C. A. Parsons & Co., Ltd.; Dr. H. J. Gough, engineer in chief, Lever Bros. & Unilever, Ltd.; Sir William Halcrow; Mr. M. B. Hoseason, Brush Electrical Co., Ltd.; Dr. C. H. Lander, principal, Military College of Science; Prof. N. F. Mott, Melville Wills professor of theoretical physics, University of Bristol; Prof. D. M. Newitt, professor of chemical engineering, Imperial College of Science and Technology, London; Sir Ewart Smith, of Imperial Chemical Industries, Ltd.; Prof. H. W. Swift, professor of engineering, University of Sheffield; Dr. C. Sykes, director, Brown–Firth Research Laboratories.

British Committee for Co-operation with U.N.E.S.C.O. in the Natural Sciences

At the invitation of the Ministry of Education, the Royal Society has set up a committee to cooperate with the United Nations Educational, Scientific and Cultural Organisation in the field of the natural sciences. The Committee's terms of reference are: (i) on behalf of the United Kingdom, to co-operate with U.N.E.S.C.O. in the field of the natural sciences; (ii) to report to the Council of the Royal Society and to the Minister of Education.

The Committee consists of a chairman, Prof. E. D. Adrian (foreign secretary of the Royal Society), and representatives (as indicated in brackets) of the following bodies: Royal Society (Dr. C. H. Desch, Dr. J. Needham, Prof. H. H. Read); chairmen of the seven British National Committees (Astronomy—Sir Harold Spencer Jones; Biology—Prof. H. M. Fox; Chemistry—Sir Ian Heilbron; Geodesy and Geophysics—Prof. J. Proudman; Geography—Prof. H. J. Fleure; Physics—Prof. N. F. Mott; Scientific Radio—Sir Robert Watson-Watt); Ministry of Education (Mr. Ritchie Calder, Prof. H. J. Fleure, Sir Clive Forster-Cooper); Advisory Council on Scientific Policy (Dr. A. E. Trueman); British Association (Dr. E. Hindle, Dr. O. J. R. Howarth); British Council (Dr. N. Howard Jones, Miss Nancy Parkinson); Association of Scientific Workers (Prof. J. D. Bernal); Science Masters' Association (Mr. J. P. Stephenson); Department of Scientific and Industrial Research (Sir Edward Appleton); Medical Research Council (Sir Edward Mellanby); Agricultural Research Council (Sir John Fryer); secretary of the Universities Bureau of the British Empire; and *ex officio*, the president, treasurer and one secretary of the Royal Society. The joint secretaries of the Committee are Mrs. J. J. Hawkes, of the Ministry of Education, and Dr. D. C. Martin, assistant secretary of the Royal Society. In accordance with the proposal by the Ministry of Education, the Council of the Royal Society has agreed that other important scientific organisations in the United Kingdom should be notified of the existence of the Committee and invited to transmit to the secretariat any proposals which they may wish to initiate. The first meeting of the Committee will be held on June 27.

Agricultural Science at Newcastle-upon-Tyne

The scope of instruction and research in agriculture at King's College, Newcastle-upon-Tyne, is to be extended. Two new chairs have been founded, the occupants of which will carry out their work under the direction of Prof. R. W. Wheldon, the present head of the department. The Loveday Report recommended the setting-up of post-graduate schools in agriculture and farm machinery for graduates in engineering who intend to become agricultural engineers, and in engineering and farm machinery for graduates in agriculture who intend to become farm mechanization experts. King's College, which has a strong engineering school, has been selected as a centre for this specialized work.

Lieut.-Colonel Ewen McEwen has been appointed the first professor of engineering in the Faculty of Agriculture. At University College, London, in 1935 he gained a first-class honours in mechanical engineering. Until 1942 he held a research appointment with David Brown and Sons (Huddersfield), Ltd., and afterwards served with the R.A.O.C. and R.E.M.E. More recently, as assistant chief engineer in the Fighting Vehicles Design Department of the Ministry of Supply, he has become conversant with fundamental problems of traction in relation to soil structure.

King's College has acquired Cockle Park, Northumberland, where far-famed experiments on the control of grassland and on ley farming in general have been in progress for many years. It is intended to develop chemical, botanical and husbandry aspects of these experiments. With the appointment of Mr. Martin Jones to the newly instituted chair of agricultural botany, the further investigations of the botanical problems will be under experienced guidance. Mr. Martin Jones graduated in science at the University College, Aberystwyth (University of Wales). He has since done much work and published papers on plant breeding and grassland improvement. Under the auspices of Imperial Chemical Industries, Ltd., he was concerned with the early experiments on the effects of controlled grazing at Jealott's Hill. For a period he acted as an assistant to Sir George Stapledon. In recent years he has been advisory officer in grassland management at the North of Scotland College of Agriculture, Aberdeen.

South African Marine Expedition

The discovery of a living Cœlacanthid fish, *Latimeria chalumnœ*, in South African waters, off East London, at the end of 1938, is an event still in the forefront of the minds of biologists (see *Nature*, **143**, 455 and 748; 1939). The published account of the mounted animal is as exhaustive as the material permitted, but all zoologists desire information about the soft parts of the creature, which in this case were lost before they could be examined. The outbreak of war in 1939 put a stop to preparations for expeditions to seek further specimens of this remarkable fish. Now that the War is ended, general interest in this project has been shown in various countries, and in South Africa in particular. The South African Council for Scientific and Industrial Research has appointed a committee to consider how best to organise a marine expedition on a considerable scale. This expedition would aim not only at securing more cœlacanths, but would also explore and accumulate data in various fields of science in the relatively poorly known region of the Mozambique Channel. The committee is under the chairmanship of Dr. S. H. Haughton, director of the South African Geological Survey, and a member of the Council for Scientific and Industrial Research. The honorary secretary of the committee is Prof. J. L. B. Smith, of Rhodes University College, Grahamstown, and the committee requests that all societies, institutions and private persons interested in the project should communicate with him.

Refresher Courses for Science Teachers

TERMINATION of a student's normal course of study often brings to an abrupt end his active connexion with the university. In the case of science teachers, this is particularly undesirable, for it is important that the rapid developments which are taking place in their subjects should be fully discussed between school and university teachers, especially in relation to teaching methods. With these considerations in view, a ten-day course on modern aspects of chemistry was recently held at the University College of North Wales, Bangor, in co-operation with the Welsh Department of the Board of Education, one of the inspectors of which, Dr. D. M. Williams, assisted in the organisation of the course. Summaries were given of recent work on atomic structure, valency theory and its application to problems concerning the structure and reactions of some inorganic and organic compounds, the electro-chemistry of solutions, and the chemistry of natural and synthetic products of special interest; lectures and experiments were included illustrating advances in the theory and practice of *p*H determination, indicators, electrometric titrations, distillation, and chromatography, together with a demonstration of glass-blowing technique, a show of scientific films and a display of modern books, dealing especially with the subjects selected. While it was apparent that the teachers attending the course derived benefit and interest from it, the discussions proved most stimulating also to the University personnel who participated. The course was conducted by Prof. E. D. Hughes and Drs. W. R. Angus, I. Dostrovsky, J. Graham and D. R. Llewellyn, assisted in the experimental work by Dr. F. Brown, Mr. T. R. Jacobs, and senior research students; Prof. C. W. Davies and Dr. W. C. Evans, of University College, Aberystwyth, gave special lectures.

Library Service in Industry

A WELL-ATTENDED conference on "The Works Library", organised at Sheffield on March 27 by the Northern Branch of the Association of Special Libraries and Information Bureaux, was designed to help the budding works librarian to appreciate the scope of his work and the resources at his disposal. The chairman of the Conference, Mr. W. H. Higginbotham, chairman of Messrs. Edgar Allen and Co., Ltd., at the opening session, when the Association was welcomed by the Lord Mayor of Sheffield, emphasized the extent and diversity of knowledge required in industry and the importance of ensuring at all levels a sufficiency of knowledge and specialized information for the successful operation of an industrial or business undertaking, and of providing for its co-ordination and combination into an effective working tool. This is the essential task of the Association, and in the two papers presented at the morning session, "Pages from the Diary of a Steel Works Librarian" and "A Special Library in the Steel Industry", Mr. G. H. Davison and Miss A. R. Osborne gave some account of the building up of a library and information service for the United Steel Companies, Ltd., and for Messrs. Thomas Firth and John Brown, Ltd. Mr. Davison's paper in particular covered a wide range of problems in the organisation and running of a firm's library; Miss Osborne's paper was illustrated by lantern slides, and those attending the Conference had a further opportunity of seeing the actual functioning of the information service on the following morning when parties visited the Brown-Firth Research Laboratories. Other delegates availed themselves of the invitation of Messrs. Edgar Allen & Co., Ltd., to visit their works and laboratories. At the afternoon session Mr. E. N. Simons contributed a stimulating paper on "The Works Library of To-morrow", in which he suggested a number of probable trends in works library service during the next few decades. In the concluding paper, Mr. R. Brightman discussed "Reference Books for the Works Library", dealing with the needs of a library concerned with production rather than with research, and submitting a series of lists designed to help the novitiate in charge of such a library in the selection of his or her own desk tools, general reference books, technical reference books and single-volume textbooks of the 'refresher' type; in general he only included one-volume reference works.

Recent Earthquakes

OF the first three months of 1947, January was by far the most seismic. During January there were seven world-recorded earthquakes, besides minor shocks in many parts of the earth, including two near Switzerland and nineteen in New Zealand. The Americas, the Aleutian Islands and Japan provided the world-recorded earthquakes, the greatest being on January 26 at 10h. 06·7m. G.M.T. in western Nicaragua. This was a deep-focus earthquake, the focus being approximately 160 km. deep. The first shock near Switzerland was on January 16 at 22h. 30m. G.M.T., and was felt with scale V at Stein am Rhein, and the second was on January 24 at 2h. 30·5m. G.M.T., being felt at Westalpen Savoie, France. Nineteen local earthquakes and tremors were felt in New Zealand, the greatest being on January 10 at 16h. 08·8m. G.M.T. from 46·5° S., 164° E., which was felt with Modified Mercalli Scale IV at Puysegur Point.

During February there were two world-recorded earthquakes: on February 10 and 24, the latter having its epicentre in Japan. Several local tremors occurred, one of the largest being that on February 17 at 00h. 13m. at Piémont, France, with strength 5–6, being felt as far as Marseilles, Nice and Grenoble.

In March a strong earthquake occurred in China (epicentre 33·5° N., 100·0° E.) on March 17 at 8h. 19·5m. G.M.T., and on March 26, an hour after the Wellington Observatory, New Zealand, had reported a strong earthquake out at sea, the first seismic sea wave some 30 ft. high rolled up on a 60-mile stretch of the shore of Poverty Bay. This wrecked some waterside houses and shops at Gisborne and damaged some roads and bridges. At Gisborne some of the streets were 4 ft. under water. Half an hour after the first *tsunami*, a second arrived. Fortunately, the people on the sea-front saw the waves coming and got on to higher ground, so that no loss of life has been reported.

Institution of Mechanical Engineers: Centenary Exhibitions

IN connexion with the centenary celebrations of the Institution of Mechanical Engineers, during the week commencing June 8, an exhibition of Stephenson relics will be open to the public at the Institution at Storey's Gate, St. James's Park, London, S.W.1, during June 9–13 between 10 a.m. and 5 p.m. There are personalia and numerous prints, drawings and other material on loan from individuals and institutions.

A special exhibition is also being held in the Science Museum, South Kensington, during June 10–August 24 to commemorate the founding of the Institution in 1847. This exhibition, covering a century of mechanical engineering, is divided into several sections including mechanical plant for power stations; locomotives; automobile, marine and aero-engines; hydraulic and handling machinery, etc. Important historical objects are shown in their appropriate galleries. Modern exhibits are displayed in Gallery 1. Scale-models made specially for this exhibition include the steam turbines of the R.M.S. *Queen Elizabeth* and a Southern Railway 'West Country' steam locomotive. Most exhibits, such as automobile and aero-engines, models of high-pressure boilers, steam and gas-turbines, have never been shown in the Science Museum before.

Conference on Liquid Helium

A CONFERENCE on liquid helium will be held at the Clarendon Laboratory, Oxford, during June 27–28. The programme includes discussions on the general and quantum theories of liquids (Prof. Max Born and Dr. H. S. Green respectively), the 'cage' model of a liquid (Dr. H. N. V. Temperley), zero-point energy of thin helium films (Prof. N. F. Mott), properties of helium films (K. R. Atkins, J. B. Brown and Dr. K. Mendelssohn) and Heisenberg's new theory of superconductivity (Prof. M. H. L. Pryce). Particulars of the conference can be obtained from Prof. F. E. Simon, Clarendon Laboratory, Parks Road, Oxford.

Summer Symposium on Sound Absorption and Reverberation

THE Acoustics Group of the Physical Society is holding a Summer Symposium on June 26 at the Royal Institute of British Architects. The discussions will open at 10 a.m. with a paper on "Panel Absorbents of the Helmholtz Type", by Prof. P. V. Bruel, of the University of Gothenburg. In the afternoon Mr. J. Moir, of the British Thomson-Houston Co., Ltd., will speak on "Reverberation Time as an Index of Room Performance". The meeting is open to all who are interested in acoustics, but they are asked to notify the joint secretaries of the Acoustics Group at the offices of the Physical Society at 1 Lowther Gardens, Prince Consort Road, London, S.W.7, if they intend to be present, in order that necessary arrangements can be made.

Scottish Summer Schools in Health Education

EACH year the Scottish Council for Health Education sponsors three residential summer schools at convenient centres. These schools are of interest to doctors, teachers, health visitors, nurses, youth leaders and others, who feel that integrated courses in physiology, psychology and social medicine will help them in their professional work. The schools are residential, last for fourteen days, and provide a total of twenty-seven lectures by men and women eminent in their special fields. Students may enrol for an elementary or intermediate course at the Universities of Edinburgh and St. Andrews, respectively, both from July 26 to August 9, or take an advanced course at Strathpeffer Spa during August 8–22. There are still a number of vacancies at the Edinburgh and St. Andrews schools, but only a very few at Strathpeffer, which, already, has attracted nearly a hundred students. Further information can be obtained from the Secretary, Scottish Council for Health Education, 3 Castle Street, Edinburgh, 2.

University of London: Appointments

THE following appointments in the University of London have been announced: Dr. Harry Jones, reader in mathematics at the Imperial College of Science and Technology, to the University chair of mathematics tenable at the College as from October 1, 1946; Dr. Alan Kekwick, to the University chair of medicine tenable at Middlesex Hospital Medical School as from October 1, 1946; Mr. M. E. L. Mallowan, to the University chair of western Asiatic archæology tenable at the Institute of Archæology as from May 1, 1947; Mr. Mallowan has conducted excavations at Arpachinah, the first settlement of the Tel Halaf culture to be scientifically excavated, also at Chagar Bazar and in the Tel Brak district; Dr. H. W. Miles, during 1943–46 adviser and senior lecturer in agricultural entomology in the University of Bristol, to the University chair of horticulture tenable at Wye College as from May 1, 1947; Mr. R. S. Sayers, during 1935–45 lecturer in economics at Pembroke, Exeter and Corpus Christi Colleges, Oxford, to the Sir Ernest Cassel chair of economics with special reference to banking tenable at the London School of Economics as from May 1, 1947; Mr. Herbert Tout, senior lecturer in economics at the University of Bristol, to the University readership in political economy tenable at University College as from October 1, 1947; Dr. W. J. Hickinbottom, since 1927 lecturer in chemistry in the University of Birmingham, to the University readership in organic chemistry tenable at Queen Mary College as from October 1, 1947; Dr. E. S. Horning, formerly of the permanent scientific staff at the Imperial Cancer Research Fund Laboratories, to the University readership in experimental pathology tenable at the Royal Cancer Hospital as from May 1, 1947; Dr. F. C. Tompkins, lecturer at King's College, to the University readership in physical chemistry tenable at the Imperial College of Science and Technology as from October 1, 1947.

The title of professor emeritus of chemistry in the University has been conferred on Dr. James F. Spencer on his retirement from Bedford College. The title of professor of comparative education in the University has been conferred on Dr. J. A. Lauwerys in respect of the post held by him at the Institute of Education.

The degree of D.Sc. has been conferred on O. V. S. Heath (Imperial College of Science and Technology); and S. S. Joski (University College).

Announcements

SIR LIONEL WHITBY, regius professor of physic in the University of Cambridge, has been elected master of Downing College, Cambridge, in succession to the late Sir Herbert Richmond.

A NATIONAL meteorological service has been established in Portugal under the direction of Prof. H. Amorim Ferreira. The headquarters of the new service is Serviço Meteorológico Nacional, Largo de Santa Isabel, 2–Lisboa (Portugal).

THE following officers were elected at the annual general meeting of the Society for Endocrinology held at University College, London, on May 29: *Chairman:* Dr. A. S. Parkes; *Secretary:* Dr. S. J. Folley, National Institute for Research in Dairying, Shinfield, Nr. Reading; *Treasurer:* Dr. C. W. Emmens; *Editor of the Society's Proceedings:* Prof. S. Zuckerman; *Members of Committee:* Dr. P. M. F. Bishop; Dr. C. H. Gray; Mr. P. C. Williams; Prof. F. G. Young.

ERRATUM. In the communication "Temperature-Dependence of Magnetic Susceptibility of Annealed and Cold-worked Copper" (*Nature*, April 19, p. 537), par. 2, line 4, for "0·005 per cent" read "0·0005 per cent".

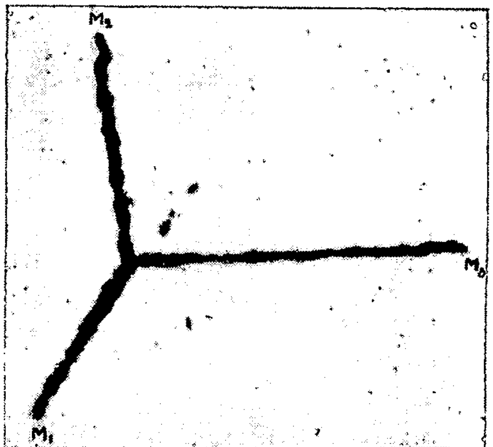
Ternary and Quaternary Fission of Uranium Nuclei

After our experimental proof of the existence of tripartition and quadripartition (ternary and quaternary fission) of U^{235} by means of photographic emulsion[1,2], a systematic study of the mass and kinetic energy of fission fragments has been made with the Ilford Nuclear Research C_2 plate. The experimental conditions were similar to those of previous work. C_2 plates soaked with 10 per cent solution of uranyl nitrate were bombarded with slow neutrons produced near the beryllium target of the cyclotron of the Collège de France.

The results of the first series of experiments can be summarized in the following[3,4].

Tripartition. Usually two of the fragments are heavy (m_1, m_2) and the third one is light (m_3) (Fig. 1). The mean ranges of m_1 and m_2 are 1·9 and 2·3 cm. of air equivalent, while that of m_3 varies from 2 to 44 cm., the most frequent value being about 25 cm. The direction of emission of m_3 is nearly perpendicular to that of m_1 and m_2. The mass distribution of m_1 and m_2 has mean values of 99 and 131, whereas in the usual binary fission the most frequent masses are 96 and 138. The third fragment, m_3, seems to have two probable values, one about 5, the other about 9. Some cases, which could be interpreted as tripartitions, could be also interpreted by the mechanism of projection of atoms of carbon, nitrogen or oxygen ($m \sim 14$) or silver or bromine ($m \sim 90$) by a fission fragment; fission tracks of this kind were not counted in the statistics of tripartition. The total kinetic energy of the three fragments, about 155 MeV.[5], slightly higher than that of the usual binary fission fragments (150 MeV.), is in good agreement with the theoretical prediction[6]. The frequency of tripartition is about 1/300 of that of bipartition (usual fission process).

A parallel and independent investigation by Demers[7] shows that the third light fragment (considered as an α-particle) is emitted within 2 × 10^{-14} sec. after the act of division. This is in good agreement with our hypothesis of tripartition, namely, that three fragments are emitted in an interval of time comparable with the mean life-time of the compound nucleus $_{92}U^{236}$. The frequency observed by Demers is also in agreement with ours.



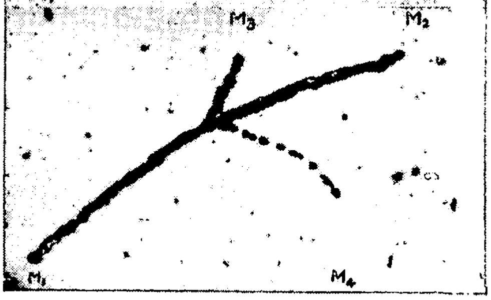


Fig. 2 (above); Fig. 3 (below)

Fig. 2. TRIPARTITION OF URANIUM NUCLEUS WITH THREE FRAGMENTS OF COMPARABLE MASSES: $m_1 = 127$; $m_2 = 77$; $m_3 = 32$

Fig. 3. QUADRIPARTITION OF URANIUM NUCLEUS

Recently, we have observed a particular case in which the third fragment is much heavier (Fig. 2). The calculated masses are about 127, 77 and 32 respectively. The three fragments are almost coplanar, their ionizations are much higher than that of α-particles and the total kinetic energy is about 142 MeV. This observation and the direction of emission of m_3 support the explanation in terms of tripartition[8,9] which is possible with a large positive amplitude of the deformation due to the fourth harmonic of the liquid drop (Bohr's liquid drop model of the nucleus). The relative sizes of the fragments (droplets) depend upon the amplitudes and the phases of deformations due to the second and fourth harmonics. Consequently, it is natural that the third fragment should have different values of mass such as we have observed. An analysis of fission fragments in the region of lower atomic weight by means of the mass spectrograph with a strong neutron source might give more information concerning the mass distribution of third fragment.

Quadripartition. The first case of quadripartition has already been published in detail[3,5]. Another one is shown in Fig. 3. The four fragments are not coplanar. The calculated masses are: $m_1 = 84$, $m_2 = 76$, $m_3 = 72$ and $m_4 = 4$, with a total kinetic energy about 90–95 MeV. If the internal excitation energies of the fragments are about the same both for binary and quaternary fissions, the observed total kinetic energy for the latter is in good agreement with that estimated by Bohr and Wheeler. The frequency of quadripartition is about 1/3,000 that of bipartition.

A detailed report of this work will be published shortly in the *Journal de Physique et Le Radium.*

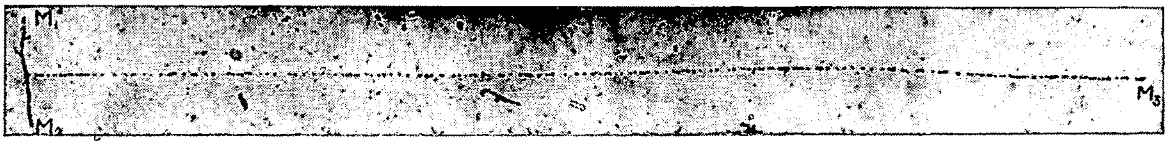

Fig. 1. TRIPARTITION OF URANIUM NUCLEUS WITH LIGHT THIRD FRAGMENT (ITS RANGE IN STANDARD AIR = 44 CM.). THE TWO BRANCHES ON M_1 TRACK ARE DUE TO NUCLEAR COLLISIONS OF M_1 WITH KNOWN NUCLEI CONTAINED IN PHOTOGRAPHIC EMULSION $m_1 = 110, m_2 = 120, m_3 = 6 \pm 1$. Total kinetic energy ~ 179 MeV.

Note added in proof.—Since this letter was written, two communications have appeared on the emission of a third light charged particle in the fission of uranium (L. L. Green and D. L. Livesey, *Nature*, March 8, p. 332 ; G. Farwell, E. Segrè and C. Wiegand, *Phys. Rev.*, March 15, p. 327). The first one, using the same technique as ours, gives similar results on the direction of emission and the range distribution of m_3 of range greater than 1 cm. of air equivalent. It shows, furthermore, the existence of an important short-range group. The second one, using the method of coincidence, gives 23 cm. as the maximum range of m_3 which has been identified as α-particle. Within experimental errors, the frequencies observed by these authors are in good agreement with ours.

In order to confirm the short-range group of m_3 indicated by Green and Livesey, we have re-examined our plates and counted those cases in which a short-range track is linked in the middle straight part of the main fission tracks. The statistics show that particles of range from 3 mm. to 3 cm. are present, the most probable range being about 8 mm. If all these tracks are really connected with the fission process, the frequency will be one short particle in 90 fission events.

Similar experiments have been made recently on the fission of uranium by fast neutrons. Short-range third light particles have been observed with the same frequency, but until now no long-range particle has been detected. Similar results have also been obtained in the case of fission of thorium by fast neutrons (observation made by the senior author in collaboration with Mrs. H. Faraggi).

An Electron Accelerator with an Air-cored Field

ARISING primarily from the fact that iron becomes saturated in the region of 10,000–20,000 gauss, high-energy ions and electrons have been obtained from cyclotrons and betatrons only by the use of magnetic fields of large orbital radii. The question has, therefore, often been raised as to the possibility of using iron-free fields of short duration, especially as fields of the highest magnitude have been obtained in this way. The following note describes an experimental resonance accelerator for electrons which uses such an air-cored field.

The principle of the accelerator has already been described[1]. Electrons are accelerated by a 1,200 Mc./s. electric field across a pair of dees situated in a magnetic field of 425 gauss. Owing to the relativity mass increase, the electrons tend to lag behind the accelerating potential, and, in order to keep them in resonance, an increasing magnetic field is superimposed on the static field. The phasing condition requires that the rate of increase of magnetic field, dH/dt, be less than $2\, Ve\,.\,n\,.\,H_0/m_0\,c^2$, where Ve is the energy added to the electrons per transit of the dee gaps, n is the frequency of the accelerating field, and H_0 is the magnitude of the static field.

A focusing static field is produced by a Helmholtz pair of coils, each of 120 turns of mean radius 11·5 cm., excited by a direct current of 48 amp. The dynamic field is also produced by a Helmholtz pair, each coil of four turns and 7 cm. radius. A condenser bank of 0·0108 μf., charged to 20,000 V., is shorted across the dynamic coils and produces a field of approximately 300 gauss at the peak of a sinusoidal oscillation of 250 kc./s. frequency. The growth of the dynamic field is synchronized with the start of the electric field pulse by using the same rotary spark modulator to control both circuits.

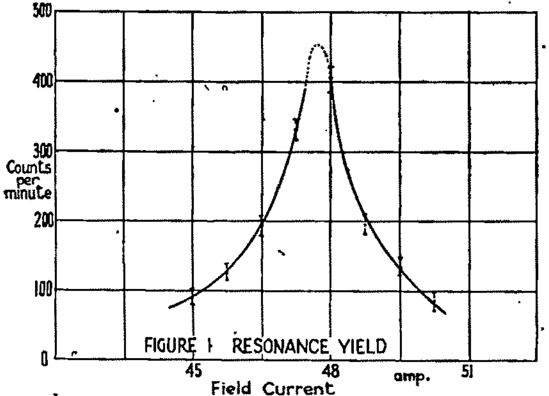
The dees are 2 cm. deep and 5 cm. in radius, and are constructed from wire hoops mounted perpendicularly from frames forming the dee gaps. They are situated in an evacuated glass vessel in the mid-plane of the Helmholtz coil system. The ultra-high-frequency is fed to the dees by a Lecher wire system which fans out to the width of the dee frames at the gaps. The oscillations are produced by a 25-cm. magnetron operating at 100 pulses per second, each pulse being of 1 μsec. duration, and of peak power up to 200 kW. The dee voltage is estimated to be of the order 1,000 V.

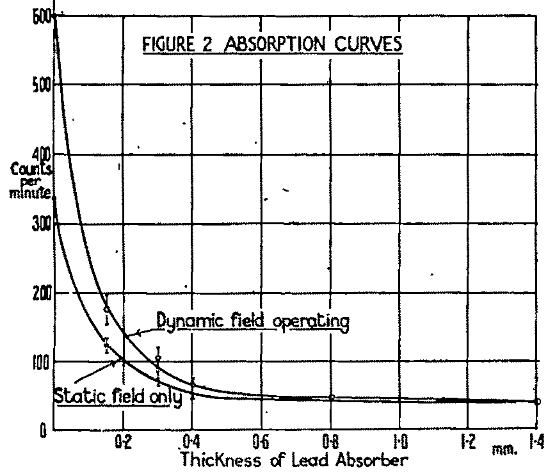
A tungsten filament, partly enclosed in a split cylindrical shield, is situated along the axis of the dees, and a small tungsten target is located at the periphery of one of the dees.

X-rays have been detected by a Geiger counter set up in the vicinity of the accelerator and are emitted at the value of the static field calculated for resonance with the electric field. The form of the resonance curve is shown in Fig. 1. Tests have been made on the X-rays produced both with and without the dynamic field operating. Absorption curves in lead are shown in Fig. 2. With the dynamic field operating it is clear that the X-ray yield is considerably increased, and there is an indication in the foot of the absorption curves that the radiation is also harder. The mean energy of the X-rays determined from the absorption coefficient in lead is approximately 60 kV.

For a constant magnetic field of 425 gauss, electrons should be able to reach energies of the order 0·5 MeV. before lagging 90° in phase behind the accelerating electric field[2]. In the present experiment, however, electrons will not attain energies greater than 100 kV. before they collide with the target at a radius of 4 cm. An experimental mean energy of 60 kV. is therefore not inconsistent with the upper limit, as it is improbable that many electrons will reach this maximum in the 1 μsec. acceleration time, and also as the radiation is from a thick target.

For a magnetic field which grows from 425 gauss to approximately 725 gauss in the micro-second acceleration-time, there should be a group of electrons which attain an energy as high as 300 kV., but an analysis of the energy spectrum to be expected of





the accelerated electrons has not yet been made. It might be added that the electron energy gained per turn as a consequence of the magnetic induction effect of the dynamic field is negligible in comparison with that gained from two transits of the dee gaps.

The X-ray yield, compared tentatively with a radium source, corresponds to 0·1 millicurie, which is equivalent to a minimum peak yield of 1 curie. The yield increases rapidly with increasing dee voltage, and a ten-fold increase is obtained for an increase of filament emission to the dees from 0·5 to 5 mA.

The accelerator described above was designed to use a 1,200 Mc./s. accelerating field, mainly because the size of the maximum orbit was suited to the construction of an experimental model; but the possibility of extending the method to accelerate electrons to high energies must be considered primarily in relation to the maximum dynamic fields which can be produced. The relationship of accelerating frequency and magnetic field to maximum electron orbit is to be seen in the accompanying table. Although fields of the order of megagauss have been obtained in small volumes, the dimensions of an accelerator using centimetre accelerating fields would raise serious problems. The most attractive combination of fields appears to be in the neighbourhood of 100 Mc./s., where the relatively low magnetic fields could probably be obtained for short periods.

VARIATION OF ACCELERATOR CONSTANTS

Frequency (megacycles)	3,000	1,200	300	30	12
Static field (gauss)	1,060	425	106	10	4
Dynamic field at 10 MeV.	22,500	8,900	2,250	225	89
Dynamic field at 100 MeV.	213,000	85,300	21,300	2,130	850
Maximum electron radius (cm.)	1·6	4	16	160	400

Magnetic Dispersion of γ-Ferric Oxide

AN account of preliminary measurements of the magnetic properties of iron oxides at wave-lengths of 9, 6 and 3 cm. has been given in an earlier communication[1]. The powdered oxides were mixed with paraffin wax, and the properties of the mixtures determined by a wave-guide impedance method. These measurements have now been extended to a wider range of mixtures, and to wave-lengths up to 60 cm.

It has been found that the Clausius–Mosotti formula, previously used for extrapolating the properties of the mixtures to 100 per cent concentration, is of only limited validity. A more general relation between the complex permeability and permittivity, $|\mu| \exp(-i\mu')$ and $|\varepsilon| \exp(-i\varepsilon')$ of the mixture, and v, the proportion by volume of the oxide, has been determined. Within the limits of experimental error, $|\mu|$ and $|\varepsilon|$ obey a logarithmic law, of the type initially proposed by Lichtenecker[2] for dielectric mixtures, namely,

$$\log|\mu| = v \log|\mu_a|$$

$$\log|\varepsilon| = v \log|\varepsilon_a| + (1-v)\log|\varepsilon_0|;$$

and the magnetic and dielectric loss tangents vary linearly with v,

$$\tan\mu' = v \tan\mu'_a; \quad \tan\varepsilon' = v \tan\varepsilon'_a,$$

where suffix a refers to the properties of the oxide, and suffix 0 to those of the paraffin wax ($\log|\mu_0| = \mu'_0 = \varepsilon'_0 = 0$).

The modified values for the magnetic properties of γ-ferric oxide previously reported[1] are included in Table 1, giving the results of measurements from 58·5 cm. to 3·08 cm.

TABLE 1

λ in cm.	58·5	39·2	29·8	22·5	15·3	8·93	5·97	3·08
$\|\mu_a\|$	21	18	16·9	12·4	8·0	3·2	1·4	0·53
μ'_a	36°	45°	51°	57°	61°	67°	65°	32°

Huttig's measurements[3] at the longer wave-lengths gave much lower values for the permeability, but this is probably attributable to porosity in the compressed samples of the oxide which he used. On this hypothesis, comparison of his value of $\varepsilon = 5 \cdot 4$ at $\lambda = 39 \cdot 5$ cm. with my value of $\varepsilon = 24$ gives $v = 0 \cdot 53$. Using this derived value of v, Huttig's measurements of μ have been extrapolated to 100 per cent concentration, and the results are given in Table 2. The value at infinite wave-length is extrapolated from the measurements of Welo and Baudisch[4], who used packed samples of known density.

TABLE 2

λ in cm.	∞	174	77·5	39·5
$\|\mu_a\|$	31	28·6	23·4	17·9
μ'_a	0	~0°	29·5°	41°

The general consistency of these values with those in Table 1 is striking, considering the range of the extrapolations.

Interpretation of Complex Roots of the *S*-Matrix

It has recently been pointed out by Kramers and Heisenberg[1] that from the knowledge of the collision cross-sections between free particles, the energy-levels of the discrete states can be deduced. For this purpose the asymptotic wave function in the continuous spectrum (for one particle under the influence of a fixed centre of force),

$$\psi = \sum_l (2l+1) P_l \left\{ S_l(k) \frac{e^{ikr}}{r} - \frac{e^{-ikr}}{r} (-1)^l \right\} e^{-i\varepsilon t}, \quad (1)$$

is considered, where S_l is the diagonal form of the S-matrix and a function of the real momentum k. The stationary states follow then from the condition $k = -i\kappa$, and

$$S_l(-i\kappa) = 0, \qquad \kappa > 0, \quad (2)$$

and, for relativistic particles,

$$\varepsilon = +\sqrt{m^2 - \kappa^2}.$$

It is evidently necessary that $\kappa < m$. The upper half of the k-plane ($\kappa < 0$) gives only a repetition of the same physical facts if the roles of zeros and poles of S are interchanged.

It was further pointed out by Møller[2] that (2) can be generalized so as to give also the levels of decaying radioactive states with their decay constants, through the condition

$$\left.\begin{array}{l} S_l(k' - i\kappa) \doteq \infty \\ \varepsilon = +\sqrt{m^2 + k^2} = W - i\lambda \end{array}\right\} \kappa > 0. \quad (3)$$

If $k' > 0$, then also $\lambda > 0$ and

$$\psi_l \sim \frac{e^{ik'r}}{r} e^{-iWt} e^{+\kappa r} e^{-\lambda t}.$$

This describes an outgoing wave with decay constant 2λ (the exponential increase $e^{+\kappa r}$ is due to particles which have been emitted a 'long time ago'). For $k' < 0$, the wave-function describes just the reverse process. It is here evidently necessary that $W > m$. This condition defines a certain region $k'^2 < \dfrac{m^2\kappa^2}{m^2 + \kappa^2}$ in the lower half of the k-plane where poles are meaningless.

Møller stated that S_l can have no zeros in the right lower quadrant of the k-plane except on the imaginary axis, where the zeros give the stationary states with energy less than m. We wish to point out that, in certain modern theories where particles can be created and annihilated, complex zeros of S in the lower half plane also have a simple interpretation. Let $S_l = 0$ for $k = k' - i\kappa$, $\varepsilon = W - i\lambda$ ($\kappa > 0$). Consider first the case $k' > 0$, and therefore $\lambda > 0$. In every case the energy W must be positive. The wave function is then

$$\psi_l \sim \frac{e^{-ik'r}}{r} e^{-\kappa r} e^{-iWt} e^{-\lambda t}. \quad (4)$$

This describes an ingoing, decaying wave. As can easily be verified, the equation of continuity (conservation of particles) is satisfied in every point except at $r = 0$. The wave is therefore swallowed up by the centre of force. It is true that such solutions cannot occur in ordinary wave mechanics but can occur in theories, for example, in the meson theory, or the theory of β-decay, where particles can be created or annihilated. The capture of a *K*-electron would be one example. It is significant that in none of these theories is a convergent Hamiltonian known to exist. Again the case $k' < 0$, $\lambda < 0$ describes the reverse process. There is no restriction as to the value of W, except $W > 0$.

As an example for the Kramers – Heisenberg theorem for which no Hamiltonian exists, we have studied the S-matrix of a nucleon-meson system in the theory of damping[3]. Neglecting all multiple processes, and considering longitudinal mesons and the charged theory only, S is given by (only for $l = 0$, $S \neq 0$), putting the meson mass $m = 1$,

$$\left.\begin{array}{ll} S \doteq \dfrac{1 + ig^2 k^3/\varepsilon}{1 - ig^2 k^3/\varepsilon} & \text{for a proton and positive meson (total charge 2)} \\ S = \dfrac{1 - ig^2 k^3/\varepsilon}{1 + ig^2 k^3/\varepsilon} & \text{for a proton and negative meson (total charge 0)} \\ \varepsilon \doteq \sqrt{1 + k^2}. & \end{array}\right. \quad (5)$$

It was shown that for total charge 2 one stationary state with $k \sim -i$, $\varepsilon \sim g^2$ (approximately) exists, ($g^2 \ll 1$). Applying the foregoing to (5), we have in addition the following complex roots and poles of S, with positive real part of the energy:

$$\begin{array}{ll} S = \infty \text{ charge 2.} & k = \dfrac{1}{g}\dfrac{1 - i}{\sqrt{2}}, \quad \varepsilon = \dfrac{1}{g}\dfrac{1 - i}{\sqrt{2}} \\ & k = -\dfrac{1}{g}\dfrac{1 + i}{\sqrt{2}}, \quad \varepsilon = \dfrac{1}{g}\dfrac{1 + i}{\sqrt{2}} \end{array} \quad (6)$$

$S = 0$, charge 0. The same values of k and ε as in (6).

No solutions of $S = 0$, charge 2, or $S = \infty$, charge 0, exist with k in the lower half-plane (except with negative energies, which have to be excluded). Thus we see that a metastable isobar with charge 2 and energy greater than 1 exists, which decays exceedingly rapidly. For practical purposes, this state can be considered as free. Furthermore, a metastable state exists for charge 0, with the negative meson being swallowed up by the proton ($k' > 0$); and also the reverse process, with the negative meson emitted by the neutron ($k' < 0$). Such states are likely to occur in a theory where particles can be emitted and absorbed. This example is given as an illustration of the general theorem, but in view of the preliminary character of the theory of damping the results should not be taken as physical facts.

It appears that almost all zeros and poles of S have a simple physical interpretation. Certain regions only are meaningless : for poles the region $W < m$, and for the zeros the part of the imaginary axis $\varkappa > m$.

Units in Photo-Electric Absorptiometry

Koch and Kaplan's criticism[1] of the E (1 per cent, 1 cm.) value does not distinguish between absolute and abridged spectrophotometers[2]. The context indicates that only the abridged type (employing light filters) is in question ; yet E (1 per cent, 1 cm.) is an essentially monochromatic convention that strictly applies to absolute instruments only, and that pertains not to colorimetry but photometry. Moreover, E (1 per cent, 1 cm.) is merely a standard expression that does not carry the implication that one must measure the optical density of a 1 per cent solution in a 1 cm. cell any more than a determination of the coefficient of expansion calls for measurements on a 1 cm. length of material heated through 1° C.

The inherent difficulties of abridged spectrophotometry have been discussed elsewhere[2]. Briefly, resolution lies in the use of (i) a standard the absorption characteristics of which closely resemble those of the test solution, and (ii) a light filter the peak transmission of which (the band being as narrow as possible) corresponds with the peak of absorption of the standard and test solution. Measurements should never be made on the slopes of absorption curves. Under these conditions good approximations to E (1 per cent, 1 cm.) values can be derived.

Koch and Kaplan rightly recognize that measurements should invariably be made at approximately the same optical density. This principle is, or at least should be, embodied in standard practice, but the density chosen depends on the instrument ; for example, 0·43 is best for the ordinary photo-electric absorptiometer[3], and 1·2 for a photographic spectrometer[4]. No instrument known to us has its maximum sensitivity at the proposed optical density of 0·301 (that is, 50 per cent transmission).

The problem, therefore, reduces to the mode of expression of the absorption, and it seems to us that the well-established E (1 per cent, 1 cm.), obtained by extrapolation from the strength and optical density of the cell solution, has this important advantage over the 'half-value' $W^{50}_{1\,\text{cm.}}$

$$[= (\log 2)/100 \times E \text{ (1 per cent, 1 cm.)}] :$$

it is directly related to quantity, whereas the latter employs minute decimal fractions inversely related to quantity and consequently difficult to assess rapidly at sight.

Incidentally, may we take this opportunity of pleading for the adoption of "E (1 %, 1 cm.)" in place of "$E^{1\%}_{1\,\text{cm.}}$", which is not only inelegant typographically but also introduces an awkward piece of type-setting for the printer.

Luminous Phenomena in Oxygen

PROF. J. KAPLAN[1] proposes the name 'active oxygen' for certain luminous phenomena observed by him "just as the name active nitrogen was given to similar phenomena in nitrogen". I write to point out that this is not historically correct. I say so with some confidence, having coined the phrase 'active nitrogen' myself[2]. The full title of the paper cited was "A Chemically Active Modification of Nitrogen, Produced by the Electric Discharge", and in the same paper it was shortened into "active nitrogen".

The chemical activity referred to was the combination with metals such as sodium and mercury, to form nitrides, and with organic materials to form cyanogen compounds.

Striking luminous phenomena often accompany these chemical actions, but it is wrong to regard these effects as the essence of the matter.

As a matter of fact, the number of nitrogen molecules which emit a photon of afterglow light is very small compared with the number which become chemically active. For this reason, I do not think that the afterglow should be regarded as the essential phenomenon of active nitrogen, and I do not think that in the present state of knowledge the term 'active oxygen' should be applied by analogy, when only luminous phenomena are so far known to be involved. This would only cause confusion. I may add that I am trying to compile a clear account of these matters.

Influence of 2,3-Dimercaptopropanol (*BAL*) on Blood Coagulation

SINCE the announcement by Peters, Stocken and Thompson[1] of *BAL* as an antidote for lewisite, the compound finds increasing application in the treatment of poisoning due to arsenicals[2], mercury salts[3,4] and organic mercurials[5] in humans and animals. Substances containing —SH groups are known to influence blood coagulation, for example, thiosulphate[6], cysteine[7,8] and glutathione[9]. In preliminary experiments it was observed that *BAL* was more active as an anticoagulant than cysteine. This made desirable a detailed study of the influence of *BAL* on the components of the clotting system.

The —SH compounds were dissolved in Sørensen phosphate buffer $M/15$ to produce pH 7·1–7·5, and

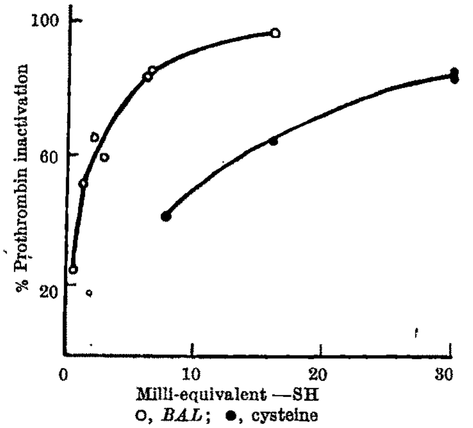
10 per cent of this stock solution was added to human oxalated plasma. The maximum effect on inhibition of coagulation was obtained after 15–30 minutes incubation at 20–28° C. Prothrombin determinations were made according to Quick's technique[10], using as source of thromboplastin either 6 per cent human or 3 per cent rabbit brain suspension and 0·01 *M* calcium chloride.

INFLUENCE OF —SH COMPOUNDS ON THE PROTHROMBIN TIME OF HUMAN OXALATED PLASMA

Plasma	Glutathione 10^{-2}	Cysteine 3×10^{-2}	*BAL*		Control plasma plus phosphate buffer
			7×10^{-3}	$2{\cdot}9 \times 10^{-3}$	
1	16	21	34	—	12·5
2	18	25	44	—	12·5
3	19	26	35	—	12·5
4	29	—	—	23	17·5
5	19	—	—	18	13·5
6	19	—	—	19	13·5

The concentrations are given in equivalents of —SH, and the clotting times in seconds

A comparison of the efficacy of *BAL* and cysteine was carried out and the results tabulated on the accompanying graph.



PROTHROMBIN INACTIVATION BY *BAL* AND CYSTEINE. EACH POINT ON THE CURVE REPRESENTS THE AVERAGE VALUE OF THREE DIFFERENT SPECIMENS OF HUMAN OXALATED PLASMA. FROM THE CURVE IT IS APPARENT THAT *BAL* WAS FIVE TO EIGHT TIMES MORE ACTIVE THAN CYSTEINE

It was found that *BAL* had no effect on thromboplastin prepared from rabbit's brain when incubated for varying periods up to 16 min. at 37·5° C. Further, very little alteration of the coagulability of purified fibrinogen was observed when coagulation was carried out by thrombin. The fibrinogen was prepared from human oxalated plasma according to the technique of Jaques[11]. The —SH compounds were added to give a final concentration of 10^{-2} in respect of —SH groups. The clotting time of the fibrinogen stock solution was 21 sec. throughout the period of observation, and the highest value found for the experimental mixtures was 24 sec. When oxalated plasma was used instead of purified fibrinogen, no change in the coagulation time was observed when clotting occurred by the addition of thrombin, whereas a similar —SH concentration ($1{\cdot}4 \times 10^{-3}$) had a marked effect on the prothrombin time. The influence of *BAL* on thrombin was tested by incubating it with thrombin prepared from human oxalated plasma by Eagle's technique[12]. The thrombin solutions were diluted to give convenient clotting times when tested on oxalated plasma, which served as a source of fibrinogen in these tests. A similar ionic strength as well as *p*H was employed. It was observed that thrombin required a considerably higher concentration of the —SH compound even for partial inactivation.

Most of the enzymatic reactions involved in carbohydrate fat and protein metabolism require —SH groups for their activity[13]. From the group of physiologically active substances, insulin appears to be an exception, since it is inactivated by —SH compounds. It has been found that *BAL* combines with arsenicals and metals to form non-toxic cyclic compounds, and it is a strong reducing agent. It also inactivates insulin, possibly by the destruction of the —S—S— groups[14]. *BAL* is more powerful in its detoxicating activities than mono —SH compounds. A comparison of the efficacy of —SH compounds made by Long and Farah[5] in dogs indicated that *BAL* is five to eight times more potent than glutathione or cysteine in protective action against 'Salyrgan'. It is interesting to note that a similar superiority of *BAL* has been observed in prothrombin inactivation. There is no evidence that metal ions except calcium play any part in coagulation, or are part of the prothrombin molecule. It would seem that the inactivation of prothrombin by *BAL* is due to its ability to attack the active centre in the prothrombin molecule, possibly by converting —S—S— groups to —SH radicals.

The action of *BAL* on thrombin is of a different nature. The —SH concentration required to reduce thrombin activity is thirty to forty times greater than that which inactivates prothrombin to a similar extent. In view of the fact that the conversion of fibrinogen to fibrin by thrombin is inhibited by many compounds, including neutral salts, when used in concentrations comparable to those employed in this study, the effect cannot necessarily be considered specific.

The dosage for the treatment of metal poisoning is given as 4–5 mgm. *BAL*/kgm. body-weight. Using a 10 per cent solution in peanut oil, rabbits were injected intramuscularly with 5–7 mgm. *BAL*/kgm. body-weight.

No change in whole blood coagulation time or prothrombin activity could be detected when plasma samples were taken one and two and a half hours after the injection.

Although the effect of *BAL* on coagulation *in vitro* is pronounced, it does not appear likely that this substance will produce hæmorrhagic tendencies *in vivo*.

Fibrinolytic Activity of Normal Urine

It has been established that human plasma contains an active fibrinolytic and proteolytic enzyme (plasmin), its inactive precursor (plasminogen), and also an inhibitor (antiplasmin) that normally overneutralizes the enzyme[1,2]. Plasmin and plasminogen are associated with the globulin fraction, antiplasmin with the albumin. Fibrinolytic activity can be induced in plasma by the addition of chloroform, which destroys antiplasmin, or of streptokinase, which activates plasminogen. Activity also occurs spontaneously in human subjects who have suffered surgical operation[3], trauma, fear[4], strenuous exercise, or the injection of adrenalin[5].

The last of these observations revealed the fact that the activity induced by these means disappeared from the circulating blood within a few minutes of the cessation of the stimulus, suggesting that plasmin is rapidly inactivated or eliminated. Among other possibilities its excretion by the kidney was considered, and the consequent examination of the urine by methods already described for plasma fractions[2] has, in fact, demonstrated considerable fibrinolytic activity in all samples examined. This activity existed even when no stimulus had been applied, and though it varied in intensity in the same subject from time to time, and from one subject to another, it was, on the average, four or five times greater than that of active plasmin, complete lysis of fibrin being produced within 24 hours by urine diluted 1/2,000–1/4,000. Though this titre increased considerably after exercise, the amount of urine passed was so much less as compared with control periods of rest that the total active principle excreted was not significantly greater than normal, and it seems improbable that the post-exercise fall in blood-plasmin can be explained by its simple elimination by the kidney.

Nevertheless, in some respects the fibrinolytic agent of urine resembles plasmin. It is not diffusable, being retained by 'Cellophane'. It is precipitated by 50 per cent saturation with ammonium sulphate, full saturation with sodium sulphate, or by bringing the *p*H of the urine to 5·5 after removing all electrolyte by dialysis. It is also precipitated by 50 per cent alcohol or acetone. It will digest fibrinogen, fibrin, albumin and casein, as judged by estimation of acid soluble tyrosine. The *p*H of optimum activity is 7·4, and of maximum heat stability 6·8, these being very close to the corresponding figures for plasmin.

There are, however, points of difference. The urine factor is less heat-labile than plasmin, 5 per cent activity remaining after 30 min. at 80° C., but it is totally destroyed by boiling. The urine factor is inhibited by antiplasmin and soya-bean trypsin inhibitor, and this inhibition is relatively more effective per unit of activity than is the case with plasmin. Plasmin is very strongly adsorbed by fibrin; the urine factor less so.

It is not certain at present, therefore, what relationship the proteolytic enzyme of the plasma bears to the rather similar factor present in the urine. Neither the points of similarity nor of difference are conclusive evidence for or against the two being identical. However, the existence of such an activity of urine is itself of some interest.

Previous observations on the proteolytic activity of urine are few. Loeper and Baumann[6] studied the excretion of 'pepsin' in the urine of normal and pathological subjects, and there is a recent paper on the urinary content of a similar enzyme, with a review of other references, by Farnsworth, Speer and Alt[7]. In view of the clear-cut differences between the properties of pepsin and those of the agent described here, this previous work probably has little bearing on the present observations.

Use of Trypsin in the Detection of Incomplete Anti-*Rh* Antibodies

In an attempt to define the properties of the enzyme present in the filtrate of a culture of vibrio cholera, which causes cells sensitized with an 'incomplete' anti-*Rh* antibody to agglutinate[1], cultures of other organisms and pure enzyme preparations have been tested. During this investigation trypsin has been found to cause agglutination of cells sensitized with an 'incomplete' antibody, and also to enhance the specific agglutination of other hæmagglutinins in the absence of any detectable antibody of the 'incomplete' type.

If trypsin is added to the serum or to the cell antigen antibody mixture, its action may be inhibited by the natural trypsin inhibitor present in all sera[2]. This can be overcome by the addition of an excess of the enzyme or removal of the serum inhibitor, or by washing cells already sensitized before exposing them to the trypsin; if this latter method is used, a single washing is sufficient to remove the inhibitor. Test cells may also be incubated with trypsin and, on incubation with sera, show enhancement of agglutination with *iso*agglutinins and immune agglutinins, and agglutination with sera of the 'incomplete' type; and after such treatment are not susceptible to the normal serum inhibitor or to soya bean trypsin inhibitor. With fresh undiluted sera, however, there is also enhancement of rouleau formation, which can be abolished by the addition of saline.

In this investigation the trypsin preparations used have been crystalline trypsin (Plaut Research Laboratory, New Jersey) and *liquor trypsini co.* (Allen and Hanbury). The stock solution of crystalline trypsin has been a 1 per cent solution in $N/20$ hydrochloric acid, and has remained stable for three months. Before use the stock solution is diluted with phosphate buffer (*p*H 7·2) to a concentration of 1 : 400 to 1 : 10,000; and the *liquor trypsini co.* is diluted with buffer to give a final concentration of 1 : 5 of the original solution. With a 1 : 400 solution of crystalline trypsin, complete agglutination of fully sensitized cells occurs within 20 min. With increasing dilution of the enzyme the time of agglutination is lengthened.

As with the enzyme present in the filtrate of vibrio cholera, trypsin appears to act on the surface of the red cell but does not affect any of the known hæmagglutinogen loci. Neither removal of the normal trypsin inhibitor from an 'incomplete' serum nor the incubation of inhibitor-free serum with trypsin for up to 30 hr. has changed the type of reaction of the sera from the 'incomplete' to the agglutinating form. After incubation the sera still show the blocking reaction[3], though the 'Coombs'' test[4] is markedly weakened.

In the detection of incomplete anti-*Rh* antibodies some of the reagents are difficult to obtain or the methods are laborious for routine use. The trypsin method is very simple in execution and only requires a standard pharmaceutical preparation as a reagent. The crystalline trypsin solutions have given positive results in parallel with the Coombs' test with twenty incomplete anti-*D* sera and also with cells sensitized *in vivo* in infants suffering from hæmolytic disease of the newborn.

The full results of these findings, together with considerations of the part they play in agglutination and in the elucidation of the nature of the incomplete antibody, will be published later. We are indebted to Dr. Kunitz for the soya bean trypsin inhibitor and to Dr. A. H. T. Robb-Smith and Dr. R. G. Macfarlane for much help and advice.

Succinoxidase Activity of Hepatic Tumours Produced in Rats by Feeding 2-Acetaminofluorene

THE succinoxidase content of experimental tumours of various origins, as well as of spontaneous tumours, has been found to be low[1-6]. In agreement with these findings in experiments conducted here, a low succinoxidase activity was found in hepatic tumours produced by feeding *p*-dimethylaminoazobenzene[7]. In a series of experiments, however, the completion of which has been delayed for technical reasons, it was observed that hepatic tumours produced by feeding 2-acetaminofluorene have an exceptional position in so far that the succinoxidase content of these tumours is about the same as, or but very slightly lower than, that of livers from normal rats on the same diet without the carcinogenic compound.

The experiments were carried out on piebald and albino rats weighing about 100 gm. at the beginning of the experiment. They received a diet containing 13 per cent of its caloric value as protein and 30 per cent as fat and 2-acetaminofluorene in a final concentration of 0·07 per cent. The succinoxidase activity was estimated in the Warburg apparatus, in both slices and homogenates. The results obtained are summarized below, the values given being means from six animals; the ranges follow in brackets.

For homogenates in the presence of sodium succinate, oxygen uptake (c.mm.) per 1 mgm. initial dry weight per hour without added cytochrome C was: (*a*) control livers, 15·6 (9·5–19·5); (*b*) liver tissue of animals bearing hepatic tumours, 16·4 (13·8–18·7); (*c*) tumour tissue, 14·9 (9·8–21·8). The succinoxidase activity in the presence of excess cytochrome C was: (*a*) 27·9 (16·2–48·0); (*b*) 30·3 (18·8–44·5); (*c*) 25·2 (13·8–43·8).

For slices the corresponding values for succinoxidase activity per 1 mgm. final dry weight were: (*a*) 38·4 (35·3–45·0); (*b*) 32·6 (28·0–36·7); (*c*) 27·4 (20·3–39·4). The oxygen uptake of the slices without addition of a donor were: (*a*) 9·4 (7·0–11·3); (*b*) 10·1 (8·8–11·3); (*c*) 9·2 (4·5–12·5).

Histologically the tumours were solid hepatomas, but each liver contained a small number of cystic and non-cystic cholangiomas. The tumours were multifocal, and metastases in the regional lymph glands and in the lungs were found. The tissue referred to as 'liver' (*b*) showed on microscopical examination usually small nests of neoplastic tissue. Nevertheless, no difference could be established in the oxidative capacity of these livers and normal livers from rats on the same diet without addition of the carcinogen.

The present experiment demonstrates that tumours from a matrix of high succinoxidase activity can retain this capacity in spite of their obvious malignancy.

I wish to express my gratitude to the Sir Halley Stewart Trust for a fellowship held during this work; my thanks are due also to the British Empire Cancer Campaign, the Anna Fuller Fund and the Jane Coffin Childs Memorial Fund for grants made towards the support of the work carried out in the Chester Beatty Research Institute.

Enzymic Modification of the Reaction Between Influenza Virus and Susceptible Tissue Cells

THE enzyme of *V. choleræ* which destroys the capacity of red cells to agglutinate with viruses of the influenza group[1] closely parallels these viruses in many aspects of its action on the red cell surface[2]. Investigations were, therefore, made to determine whether this receptor-destroying enzyme could alter the reactivity of tissue cells normally susceptible to infection with influenza virus.

Experiments, similar to those of Hirst[3], dealing with the interaction of virus hæmagglutinin and the tissue cell will be reported first. Hirst has found that the cells of the perfused, excised ferret lung rapidly adsorb influenza virus hæmagglutinin, and after a short period spontaneously release it in essentially the same way as do red cells. In the present work, the behaviour of virus hæmagglutinin was studied in the allantoic cavity of the chick embryo using eggs previously treated with the receptor-destroying enzyme as well as untreated eggs. Formalin, sufficient to kill the embryo within two hours, was administered together with the virus.

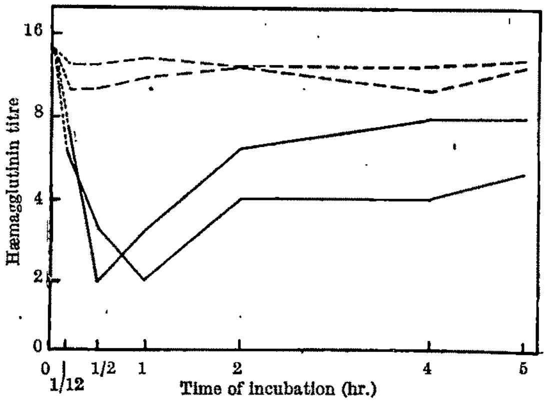

Fig. 1. GRAPH OF VIRUS HÆMAGGLUTININ TITRE IN THE ALLANTOIC CAVITY OF FORMALINIZED EGGS FOLLOWING PRE-TREATMENT WITH ACTIVE AGAR FILTRATE (RECEPTOR-DESTROYING ENZYME) (DUPLICATE EGGS) – – – – – ; BOILED AGAR FILTRATE (DUPLICATE EGGS) ———. TITRE OF VIRUS DILUTION INJECTED = 14

The allantoic cavity of a 13-day old embryo was drained, refilled with 5 ml. of saline containing the receptor-destroying enzyme, and the egg slowly rotated for 30 min. at 35° C. in a mechanical device. The fluid was again removed, and a further 5 ml. of saline containing 0·5 per cent formalin and approximately twenty agglutinating doses of swine influenza virus were injected. Samples of fluid taken at intervals over a period of four to five hours at 35° C. were titrated for hæmagglutinin content in the presence of 1 per cent sodium citrate at 4° C. in order to minimize destruction of the receptors of the indicator red cells by residual receptor-destroying enzyme. Control eggs received an initial treatment with saline or with the enzyme inactivated by boiling.

Fig. 1 expresses graphically the results of an experiment in which eggs were treated with a 1 : 10 dilution of crude receptor-destroying enzyme in the form of a Seitz filtrate prepared from soft agar cultures of *V. choleræ* and heated at 55° C. for 40 min. in the presence of excess calcium chloride[4]. Essentially similar results were obtained using the enzyme purified by elution from red cells[4], while the graphs for the eggs receiving boiled agar filtrate are similar to those of eggs receiving pre-treatment with saline only. It will be seen that in the control eggs there is rapid adsorption of virus followed by liberation after a period of three to four hours. Pre-treatment with the receptor-destroying enzyme prevents this adsorption.

Following this evidence of interference with adsorption of virus hæmagglutinin on the susceptible cell, attempts were made to prevent the onset of infection in the allantoic cavity of living chick embryos. The receptor-destroying enzyme was administered 30 min. prior to inoculation with swine influenza virus. As evidenced by the experiment illustrated in Fig. 2, administration of 0·5 ml. of agar culture filtrate brought about a highly significant reduction in the percentage of infections, whereas embryos receiving boiled agar filtrate reacted in the same way as did normal embryos. Tests with the enzyme eluted from red cells gave similar results.

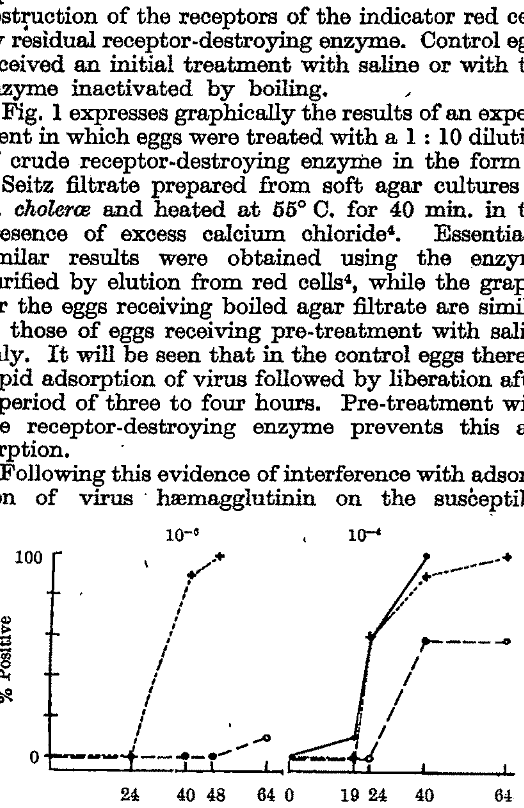

Fig. 2. EFFECT OF RECEPTOR-DESTROYING ENZYME ON INFECTION IN THE ALLANTOIC CAVITY WITH VIRUS 10^{-6} (TEN 50 PER CENT INFECTIVE DOSES) AND 10^{-4}. THE PERCENTAGE OF SURVIVING EMBRYOS GIVING POSITIVE HÆMAGGLUTINATION IS SHOWN FOR EGGS RECEIVING A PRIOR INJECTION OF ACTIVE AGAR FILTRATE (RECEPTOR-DESTROYING ENZYME) - - - - - - - ; BOILED AGAR FILTRATE ——— ; SALINE ......

These experiments, which are being continued and will be more fully reported elsewhere, lend support to Hirst's hypothesis[3] that enzymic destruction of a specific receptor substance may be a necessary step in the process of cellular infection by influenza virus. In addition, they provide further justification for the use of the red cell as a model in the study of the reaction between virus and the susceptible tissue cell.

Pulmonary Œdema and the Spleen

WHILE investigating the pharmacological properties of 2-thio-5-methyl-uracil (thio-thymine), it was noticed that this compound could be given intramuscularly to splenectomized rabbits in a dosage of 100 mgm./kgm. without ill effect, but that a similar dosage when given to normal rabbits invariably produced death from pulmonary œdema; thus, with normal rabbits, 6/6 dead in 5 days; with splenectomized rabbits, 0/6 dead after two months, and similar rabbits sacrificed two–three days after injection showed no macroscopic or microscopic signs of pulmonary œdema.

It is well known that other anti-thyroid agents (for example, phenylthiourea, thiourea and thiouracil[1,2,3]) in acutely toxic doses cause a rapidly fatal pulmonary œdema, but the fact that the spleen is necessary for the production of this œdema has not previously been noted in the literature.

The phenomenon was further investigated by making acid-aqueous (1–3 per cent acetic acid) extracts of hog and beast spleens, suspending 1 gm. thio-thymine in each 10 c.c. of the filtered extracts for six hours at 37° C., and then injecting intramuscularly the thio-thymine-splenic extract mixture (in a dosage corresponding to 100 mgm./kgm. thio-thymine) into splenectomized rabbits. These rabbits all (3/3) died from massive pulmonary œdema. The splenic extracts alone when injected into normal or splenectomized rabbits produced no obvious effects.

Further, the aqueous splenic extracts were precipitated with 7 volumes of 70 per cent alcohol, filtered, the filtrate vacuum-dried and the dried powder redissolved in water. Thio-thymine was then suspended (1 gm. per 10 c.c.) in this deproteinized splenic extract for six hours at 37° C. and the mixture finally injected intramuscularly into splenectomized rabbits, in a dosage corresponding to 100 mgm./kgm. thio-thymine. Again, all the rabbits (3/3) died with pulmonary œdema, whereas the deproteinized extracts alone were without effect when injected into control normal and splenectomized rabbits.

The dried precipitate from the alcoholic precipitation of the splenic extracts was next dissolved in water and mixed with thio-thymine at 37° C. for six hours. The mixture was then injected as before into splenectomized rabbits. 1/3 rabbits died from pulmonary œdema: the precipitate alone had no effect when injected into a control group of rabbits.

Landgrebe and Morgan[4] have noted that non-fatal doses of thiourea and thiouracil protect rats from a subsequent normally lethal dosage of thiourea. We have observed a similar effect here, in that splenectomized rabbits which have survived injection of thio-thymine do not succumb to, or show any evidence of, pulmonary œdema after injection of the thio-thymine-splenic extract mixtures.

Cultivation of Rabies Virus *in vitro*

I HAVE reported[1] that rabies virus can multiply *in vitro* in a cell-free medium containing steamed sheep-brain extract, sheep serum, glycine and peptone. The effect of the addition of certain amino-acids and accessory factors on the growth of the virus in this medium has been investigated.

Addition of tryptophan in a concentration of 2 mgm. per 100 ml. of the medium showed a stimulating effect on the growth of the virus, the concentration obtained in cultures containing tryptophan being 25 million M.L.D. per ml. as against 10 million M.L.D. per ml. obtained without it. Higher concentrations of tryptophan up to 20 mgm. per 100 ml. of the medium did not yield better results.

The effect of the addition of thiamine hydrochloride, pyridoxine hydrochloride, calcium pantothenate, nicotinic acid, riboflavin and biotin was investigated. All these accessory factors, excepting biotin, were added in a concentration of 2 μgm. per ml. of the medium. The sample of biotin available (its exact potency was not known) was diluted 1 in 10, and 0·2 ml. added per 100 ml. of the medium. The effect of these factors when added to the cultures individually and collectively was investigated.

Concentrations of virus obtained in cultures containing biotin was 100 million, with thiamine hydrochloride 75 million, with pyridoxine hydrochloride 75 million, with calcium pantothenate 75 million, with nicotinic acid 50 million and with riboflavin 50 million M.L.D. per ml. The initial concentration of virus in cultures before incubation was 50,000 M.L.D. per ml. These findings would appear to show that each of the factors tested had marked growth-promoting properties, and that biotin, thiamine hydrochloride, pyridoxine hydrochloride and calcium pantothenate were the most effective.

With the addition of tryptophan, plus all the above factors, it was possible to dispense with the use of steamed sheep-brain extract. Concentrations as high as 5,000 million M.L.D. per ml. were obtained with a medium containing 2·5 per cent glycine, 2 per cent sheep serum, 0·15 per cent peptone, 2 mgm. per cent tryptophan, 2 μgm. per ml. of each of thiamine hydrochloride, pyridoxine hydrochloride, calcium pantothenate, nicotinic acid and riboflavin, together with 0·2 ml. per 100 ml. of biotin solution. This represents about 3,000 times the concentration of virus ordinarily obtained in the brains of infected sheep used in the manufacture of antirabic vaccine.

Comparative tests carried out under aerobic, partially anaerobic and strict anaerobic conditions showed that the concentration of virus obtained in cultures incubated under strict anaerobic conditions was higher than that obtained when cultures were incubated under aerobic or partially anaerobic conditions.

Attempts were made to cultivate rabies virus in a cell-free medium containing 5 per cent glycine, 0·3 per cent peptone and 4 per cent sheep serum in distilled water. The virus inoculum consisted of the filtrate obtained by passing through a Sterimat F.C.B. pad the supernatant liquid from a centrifugalized 20 per cent suspension of fixed virus sheep brain. This was done in order to eliminate the possibility that the 'seed' might contain intact cells which may be responsible for the multiplication of the virus. One part of the virus inoculum was added to one part of the above medium, so that the final concentration of the various constituents was the same as that employed in previous experiments. The proportion of tryptophan and the other accessory factors was kept constant. The virus content of the culture before incubation was 100,000 M.L.D. per ml. After 24 hours incubation under anaerobic conditions, it increased to 2,500 million M.L.D. per ml.

It was also found possible to subculture the virus *in vitro* in this medium, provided 20 per cent steamed normal sheep-brain extract was added to it in quantities equal to the virus inoculum used as the 'seed'.

Successful cultivation of the etiological agent of rabies in a cell-free medium indicates that it is not a virus in the accepted sense of the term. This finding lends further support to earlier evidence I have obtained[2] that an agent other than a virus may be connected with the etiology of rabies.

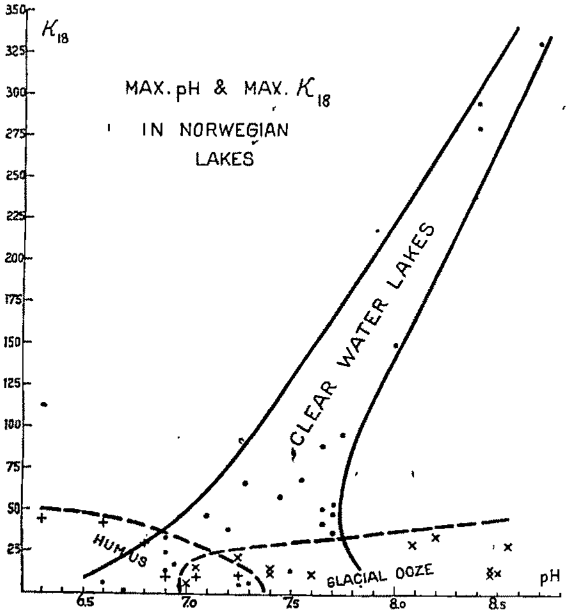
Correlation Between $\varkappa_{18}$ and *p*H in Lakes

THERE is a definite relation between specific conductivity ($\varkappa_{18} = n \times 10^{-6}$) and active reaction (expressed as *p*H, and indicating the concentration of hydroxonium (H_3O^+) ions) in lake waters. Within a single lake these values vary inversely, which really means that the concentrations of electrolytes and H_3O^+-ions move together. Biological processes deplete surface waters of carbon dioxide and dissolved salts. There is a corresponding increase in the deep, where dead organisms sinking down from the fertile, sunlit surface ('trophogenic' zone) disintegrate in the bottom waters ('tropholytic' zone). From lake to lake there is, however, a positive correlation between *p*H and $\varkappa_{18}$.



On the diagram are plotted a large number of data from various lakes in Norway, each point representing one lake. The observations are of the maxima found in each lake, irrespective of the time when the observation was made, or the depth from which the sample was collected. Thus a κ_{18}-value from the deep in autumn may be paired with a pH from surface waters in early summer. Clear-water lakes are indicated by dots; humic waters by crosses; glacial waters by crosses. From several lakes there are series from all depths, extending over one year. The lines of delimitation only refer to the data actually in the diagram, and with additional observations will certainly have to be re-drawn.

The correlation is a close one in all clear-water lakes, especially as soon as there is present an appreciable amount of electrolytes acting as buffers. Only with very low salt concentrations is there a wider range in pH, as a little free carbonic acid then suffices to change the reaction appreciably.

Very different are the brown water lakes, where stronger acids may cause a low pH, even when there is a relatively high concentration of electrolytes.

Lakes with suspended ooze from glacial melt-water frequently have a disproportionately high pH.

This may be due to an adsorption of hydroxonium ions to clay particles of colloidal size, perhaps also to alkali dissolved from freshly ground rock particles.

Vernalization of Excised Mustard Embryo

In contrast to vernalized wheat and rye, vernalized unsplit mustard seed does not become devernalized under high temperature[1]. Experiments were undertaken with mustard *T*.102 to find out whether (i) embryos excised from dried vernalized unsplit seeds would produce vernalized plants; and (ii) whether the effects of chilling excised embryos of mustard in different media would be similar to those observed by Gregory and Purvis[2] and Purvis[3] with embryos of winter rye.

Embryos excised from control- and vernalized unsplit seeds of mustard *T*.102 (dried and stored at room temperature for thirteen months) were thoroughly washed in glass-distilled water and were sown in pots on April 14, 1946. Control and vernalized whole seeds were also sown on the same date. Plants from embryos showed longer vegetative periods than corresponding plants from whole seeds on account of the lack of cotyledonary leaves in embryo plants. Similar prolongation of the vegetative periods occurred in seedlings (alike control and vernalized) when the cotyledonary leaves were amputated soon after their emergence. Plants from vernalized seeds flowered 13·5 days earlier than plants from control seeds. Plants from embryos excised from dried vernalized seeds flowered 12·5 days earlier than plants from control embryos. This proves that the embryos of vernalized unsplit mustard seeds will retain the induced vernalization for more than a year at least.

In this experiment sterile glassware and solutions were employed, and instead of the usual agar slant in test tubes, small Petri dishes containing a layer of finely powdered 'Pyrex' glass were used for chilling excised mustard embryos. After thorough washing in glass-distilled water, thirty embryos were placed in each of the Petri dishes containing: (1) Purvis's[3] modification of White's nutrient solution plus 2 per cent sucrose; (2) nutrient solution only; and (3) glass-distilled water. Three similar sets of Petri dishes with thirty embryos each were put in the chilling cabinet (2°–4° C.) on appropriate dates so that embryos chilled in the different media for one, two and three weeks were ready for sowing in pots, containing finely sifted sterile garden soil, on April 27, 1946. Intact seeds were also chilled in the same cabinet for one, two and three weeks, and were also sown on the same date, along with control embryos, and seeds germinated at room temperature for three days. The observed number of days from sowing to the opening of the first flowers is given in the accompanying table.

AVERAGE VEGETATIVE PERIODS (DAYS) OF PLANTS FROM CONTROL AND VERNALIZED EMBRYOS AND SEEDS OF MUSTARD *T*.102. (1) NUTRIENT WITH 2 PER CENT SUCROSE; (2) NUTRIENT ONLY; (3) GLASS-DISTILLED WATER. NUMBER OF PLANTS GIVEN IN BRACKETS

	Embryos Veg. period	Earliness (per cent)	Seeds Veg. period	Earliness (per cent)
Control				
(1)	Embryos discarded on account of infection			
(2)	56·17±0·63 (17)			
(3)	56·15±1·01 (13)		41·10±1·35 (19)	
Chilled:				
One week				
(1)	42·70±1·23 (10)	24		
(2)	39·64±0·36 (25)	29		
(3)	40·75±0·52 (24)	25	34·13±1·07 (23)	17
Two weeks				
(1)	36·04±0·58 (23)	35		
(2)	37·34±0·68 (23)	33		
(3)	39·22±0·64 (22)	32	29·70±0·50 (17)	28
Three weeks				
(1)	36·56±0·72 (16)	35		
(2)	36·00±0·31 (12)	36		
(3)	36·76±0·58 (13)	35	27·00±0·54 (25)	34

From the table it will be seen that embryos chilled for different periods and in different media produced plants which flowered significantly earlier than plants from control embryos. Thus, like the endosperms of monocotyledons such as wheat and rye, the cotyledons of mustard seeds are not involved in the processes of vernalization. But unlike excised embryos of rye, which according to Gregory and Ropp[4] and Purvis[3] require addition of sucrose in the medium to induce maximum vernalization, mustard embryos can be maximally vernalized even in glass-distilled water. Purvis[3] has observed that excised embryo of rye, compared to the whole grain, requires longer duration of chilling to induce any acceleration of flowering. In the case of embryos of mustard *T*.102, however, the earliness in flowering (on percentage basis) induced by chilling for one and two weeks was greater in plants from embryos than plants from intact seeds.

A detailed report of this investigation, which is being financed by the Imperial Council of Agricultural Research, New Delhi, is being published elsewhere.

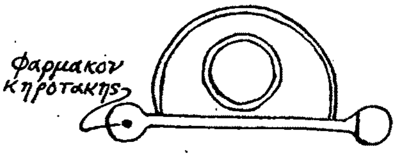
The *Kerotakis* Apparatus

Some interest has been taken in the summary of my Royal Institution lectures[1], and Dr. E. C. Stathis, of the University of Athens, has directed attention to a paper[2] by Prof. K. Zenghelis, of that University, on the *kerotakis* apparatus. Hoefer[3], who reproduced a diagram of it from a Paris manuscript[4], which[5] is copied from the old Venice manuscript[6], called it a '*bain-Marie à kérotakis*', explaining that it was not a water bath (as this name would suggest) but a sand- or ash-bath. The same name is used by Berthelot[7], who, however, gives a more adequate description of the apparatus, and in particular indicates that the name comes from that of the triangular palètte used by painters in encaustic for keeping liquid the wax pigments. He gives several pictures of the apparatus, which make it clear that there were several forms, probably destined for different uses. The one under consideration is that which I described[8] in 1929 as a small charcoal brazier, surmounted by a piece of apparatus the use of which is not immediately obvious, and in my lecture I stated that it was used for sublimation. The invention of this apparatus is attributed[9] to the early chemist Maria the Jewess (first century A.D.).

Prof. Zenghelis points out that, since the part of the apparatus above the hot plate is described as an inverted clay pot (φίαλη)[10] luted to the plate, the effects of heat on the materials inside could not be seen; and since the plate is shown in some representations[11] as projecting beyond the pot, he suggests that the ends served to support substances which by their fusion, evaporation or sublimation indicated the temperature inside the pot. Such a method of measuring temperature is still in use in the Seger cones put into pottery furnaces, and, it may be added, in preparations which change colour at definite temperatures and frequently appear in modern patents[12]. The *kerotakis* thus served as a kind of thermometer.



The correctness of this suggestion seems to be supported by a drawing which has not, so far as I am aware, been published. I give a sketch of this which I made in 1924 from a Paris manuscript[13]. It will be seen that there is a line joining the words φαρμακον κηροτακης [*sic*], that is, the materials Prof. Zenghelis thinks were used, with the edge of the plate, where he says they were placed.

There were, as I pointed out in my lecture, rival schools of chemists, the one whose teachings are mostly reproduced in the extant manuscripts being that of Demokritos. Another school seems to have followed Hermes. The commentator Olumpiodoros[14] quotes Agathodaimon as saying, from Hermes: "let it burn before the furnace (ἀπέναντι τῆς καμίνου) with the bark-like pieces of the red kobathia (κωβαθία) [= red arsenic sulphide, As_2S_2]. For the smoke of the kobathia, being white [= As_2O_3], whitens bodies [= metals such as copper]." This is the method used with such ill success by Neilos (see my lecture), who used a common fireplace instead of the refined *kerotakis* apparatus invented by Maria, of the rival school.

Interest in experiments and apparatus seems to have come into early chemistry from a Jewish source. It was foreign to Greek science; Aristoteles and Theophrastos were excellent at description, and in biology, which until recently was purely observational and descriptive, and hence their accounts seem so modern. They had little or no interest in experiment, and in Greek tradition apparatus was, apart from engines of war, almost entirely confined to toys, which reached a climax in the Byzantine period. To the two streams of Greek tradition, descriptive-biological treatment, and superstitious works such as the lapidaries and bestiaries, a third was added in the earliest chemistry, and this one, characterized by an interest in experiment and in the devising of apparatus, is uniformly ascribed to a Jewish source. Even if Wellmann's[15] thesis of an Essene origin is not accepted, his general theory seems to be plausible. I propose to develop this line of thought in detail elsewhere[16].

Kl.*, 1921, No. iv; Festugière, *op. cit.*, p. 197, thinks the correct name is 'Bolos the Demokritan', and that he may be the same as Demokritos the alchemist; I think the latter is doubtful.

[16] The relation to the conjuring tricks described by Hippolytos and the Jewish Gnostic, Markos, will also be discussed. Most of the professional magicians of the period seem to have been Jews.

THE NEW POSITION OF THE FORESTRY COMMISSION

By Prof. E. P. STEBBING
University of Edinburgh

IN *Nature* of March 17, 1945, the work of the Forestry Commission during its first twenty-five years was considered. The twenty-sixth annual report, for the year ending September 30, 1945, marks the beginning of a new phase. The report deals with the operations carried out on a more or less much diminished scale which had appertained during the war years. The total area planted by the Commission to the end of September 1945 was 469,000 acres, the total area controlled being 1,364,000 acres. The interest of the report lies in the details given on the future forest policy of Britain. Within the last thirty-five years the country has, on two occasions, for a period of years been dependent mainly on its own supplies of timber, of which in normal times of peace some 10,000,000 tons were imported annually. The two wars caused great inroads to be made on the privately owned woods of the island, for these had to supply the main bulk of the country's requirements; and the fellings—50 million cubic feet—were much heavier during the Second World War than in the First. The new State forests, the oldest but twenty years old at the outbreak of war, could supply only pit wood, from thinnings made in the oldest of the Commission areas. According to old-time accepted thinning theories in Conifers, mainly of German origin, there would have been little or nothing to come from these young British woods of twenty-five years of age and less. But investigation and observation, coupled with practice, have already demonstrated what had been expected, that in the exceptional moist and equable climate of Britain, the growth of some of the exotic Conifers surpasses that of the Conifers of Western Europe; hence earlier thinning is possible, though present experience is insufficient to lay down a rule in the matter.

The report notes that the year was a period of transition in national affairs, and the same in the Commission itself. The Forestry Act of 1945, which received Royal assent in June, changed the constitutional status of the Commission, which had been established under the Forestry Act of 1919. The progression of the new forestry work, the War and the heavy fellings in the privately owned woods, necessitated some changes in policy and administration. Up to then, the Commission had been an independent body subject only to the Treasury, which held the purse strings. In February 1945, it was announced in the House of Commons that in future the Minister for Agriculture, England and Wales, and the Secretary of State for Scotland would be responsible for forestry and forest policy in Great Britain, the Forestry Commission being retained as an advisory body with executive functions. Closer relations were to be made between the Agricultural Departments and the Commission. In practice this means that the officers serving in the Forestry Commission, of all categories, now form one of the Service Departments of the State for which a Cabinet Minister is responsible, and that forestry matters cropping up in the House of Commons will now have a Minister instead of a private member of the House, as before, to reply for and back up the forest policy already laid down. Ten Commissioners are to be maintained, and they are required to appoint committees for England, Scotland and Wales respectively, consisting partly of commissioners and their officers and partly of other persons. The commissioners will, in the words of the report, "devolve on these Committees such functions as they think fit". The new arrangement will undoubtedly make for forestry progress—the danger is that the latter will be clogged by the redundancy of committees and sub-committees which appear to be springing up all over Britain. It is difficult to foresee how these will make for either efficiency or rapidity of work, both of which are eminently desirable: the more so that the newly sanctioned forestry programme envisages the afforestation or replanting of 365,000 acres at a cost to the State of £20,000,000 spread over five years—a piece of work which will be watched with eagerness and will necessitate some rapid moving.

One outcome of the new trend given to the forest policy question in Britain is to be found in the much discussed 'Dedication of Woodlands' scheme, which in its first enunciation appeared to place all privately owned woodlands under the Forestry Commission. The first proposals were modified. The purpose of the scheme is to encourage correct management in private woods. This step is said to have become necessary in the interests of national security, because the reserves of standing timber were again greatly depleted during the War, and also because the area of land suitable and available for timber production in Great Britain is limited. The first of these contentions appears to ignore the fact that, however badly British privately owned woodlands may have been managed in the past, they did provide nearly 50 million cubic feet of timber for the War, for the growth of which the State, that is, the ordinary public, had paid nothing. But the very fact that so large a proportion of the woods of the country have been swept away makes their replacement a matter of the first importance, especially as the acres they occupied contain forest soils, a valuable planting asset which is absent on the large tracts of bare land which the Commission is engaged in afforesting. The principles underlying the scheme are: "(1) That the rehabilitation of Woodlands must proceed with both certainty and rapidity. (2) That all planting, and natural regeneration acceptable instead of replanting, must be properly looked after up to the stage of satisfactory establishment. (3) In every case the Owner must make an early decision as to whether he is prepared to proceed with the work of rehabilitation. (4) If an Owner is so prepared and can give satisfactory assurances, he is deserving of financial assistance from the State. (5) When no satisfactory assurances are forthcoming within a stated period, the State should acquire the land. (6) That the wartime system of felling licences must continue until the reserves of standing timber can be adjudged satisfactory. (7) That some degree of control of the Sylviculture of private woodlands is necessary."

The basis of the scheme, in which the State undertakes to provide certain financial assistance, is that all woodlands in Britain judged to be suitable and necessary for timber production should either be dedicated to that purpose by the owner or acquired by the State. Dedication would run with the land and would be unaffected by changes of ownership. A covenant of dedication will be entered into by which both the State and the owner undertake the respective obligations agreed upon. The covenant would provide for arbitration in the event of disagreement.

NEW YORK ACADEMY OF MEDICINE

CENTENARY AWARDS

THE end of the centenary celebration of the New York Academy of Medicine (see *Nature*, April 12, p. 494) was marked by a Convocation Meeting held on April 24. The Medal of the Academy was awarded to Dr. James Alexander Miller, an authority on tuberculosis, who has been associated with the Academy for many years and in 1937 was its president. This medal was established in 1930 by Dr. Samuel McCullagh, to be awarded periodically to a distinguished medical scientist in recognition of outstanding service to humanity.

The following were elected honorary fellows of the Academy:

Dr. J. B. Collip, director of the Research Institute of Endocrinology of McGill University, known for his work on blood and tissue chemistry, who was largely responsible for the chemical isolation of insulin; Dr. Robert Debré, professor in the Paris Faculty of Medicine, author of outstanding works in the field of pediatrics and public health; Sir John Fraser, principal of the University of Edinburgh and regius professor of clinical surgery in the University; Dr. E. W. Goodpasture, professor of pathology and dean of the School of Medicine, Vanderbilt University, who has done outstanding work on virus diseases; Dr. Evert Gorter, professor of pediatrics, University of Ghent, known for his publications on the diseases of children; Prof. Einar Hammarsten, professor of pharmacology, Karolinska Institutet, Stockholm; Dr. A. V. Hill, Foulerton research professor of the Royal Society; Dr. G. M. Holmes, consulting physician to the National Hospital of Nervous Diseases, and president of the second International Neurological Congress; Dr. B. A. Houssay, president of the Argentine Society of Biology and of the Biological Section of the Argentine National Academy of Medicine, who has made valuable contributions to our knowledge of the hypophysis and pancreatic secretion; Sir William Wilson Jameson, chief medical officer of the Ministry of Health and Ministry of Education; Dr. Otto Loewi, known for work in the field of nerve physiology and on the chemical transmission of nerve impulses; Dr. T. Madsen, formerly director of the Laboratory of the State Serum Institute in Denmark, known for outstanding work on serology and epidemiology and public health; Dr. M. Martinez-Báez, head of the Institute of Tropical Diseases and professor in the School of Hygiene, National University of Mexico; Dr. L. A. Orbeli, director of the Pavlov Institute in Leningrad, known for his work on the physiology of the nervous system; Sir John Boyd Orr, director-general of the United Nations Food and Agriculture Organisation; Dr. A. N. Richards, chairman of the Committee on Medical Research, Office of Scientific Research and Development, whose work in recent years has dealt with the function of the kidney; Prof. J. A. Ryle, professor of social medicine and head of the Institute of Social Medicine, University of Oxford; Dr. René Sand, professor of social medicine, University of Brussels; Dr. H. E. Sigerist, director of the Institute of the History of Medicine, Johns Hopkins University, known for his work on the history of medicine; Dr. A. Stampar, rector and professor of public health and social medicine, University of Zagreb; Dr. A. Tiselius, professor of biochemistry, University of Uppsala, who has made outstanding contributions to our knowledge of biologically important substances, and their separation through the development of an apparatus for electrophoresis.

The following were elected corresponding fellows of the Academy:

Dr. C. H. Best, professor of physiology, University of Toronto, co-discoverer of insulin; Dr. E. Braun-Menéndez, physiologist connected with the Institute of Biology and Experimental Medicine in Buenos Aires; Dr. E. B. Chain, lecturer in chemical pathology, University of Oxford; Prof. H. R. Dean, professor of pathology, University of Cambridge; Dr. N. Hamilton Fairley, director of special research, Hospital for Tropical Diseases, London; Sir Alexander Fleming, professor of bacteriology, University of London, known for his work on bacteriology, immunology and chemotherapy, and on penicillin; Sir Howard Florey, professor of pathology, University of Oxford, known for his work on penicillin; Dr. C. Heymans, professor of pharmacology and director of the Institute of Pharmacology and Therapeutics of the University of Ghent, who has worked on the physiology and pharmacology of the cardiovascular and central and peripheral systems and of respiration; Dr. A. Lacassagne, associate director, Pasteur Laboratory, Institute of Radium, University of Paris; Dr. G. Liljestrand, professor of pharmacology and director of the Pharmacological Institute, Karolinska Institutet, Stockholm, known for his work on the physiology and pharmacology of respiration and the circulation; Dr. J. M. Mackintosh, dean and professor of public health, London School of Hygiene and Tropical Medicine, University of London; Dr. F. de P. Miranda, director of the National Institute of Nutrition of the Ministry of Public Health and Assistance, Mexico; Dr. A. L. v. Muralt, professor of physiology and director of the Hallerianum, University of Bern; Dr. J. V. J. Parisot, professor of hygiene and social medicine and director of the Regional Institute of Hygiene, Nancy; Dr. M. Ruiz-Castañeda, director of the Department of Medical Research, General Hospital, Mexico City, known for his work on typhus and Malta fever; Dr. A. v. Szent-Györgyi, director of the Institute of Biochemistry, University of Budapest; Sir Lionel Whitby, regius professor of physic, University of Cambridge, known for work on hæmatological and bacteriological subjects.

Awards were made as follows:

Bowen-Brooks Scholarships (eight awards of 500 dollars each). Because of changing conditions, they are being given for continued study in the United States of returning young medical men: William Henry, Joseph F. Hindman, Martin H. Orens, Maurice S. Raben, E. Lawrence Reichel, C. R. Southworth, Stanley Stellar, Joseph R. Wilder.

Louis Livingston Seaman Award, for aid in investigation in bacteriology or sanitary science: Dr. James M. Neill, Cornell University Medical College (1,000 dollars); Dr. Arnold W. Pratt, Cornell University Medical College (500 dollars); Dr. A. M. Pappenheimer, New York University College of Medicine (500 dollars); Dr. Samuel Prigal, New York City (500 dollars).

Edward N. Gibbs Memorial Prize, given by Mrs. Gibbs and Mrs. Charles Sherrill (daughter): Dr. Stanley E. Bradley, College of Physicians and Surgeons (1,500 dollars).

INTERNATIONAL UNION OF THEORETICAL AND APPLIED MECHANICS

AT the Sixth International Congress for Applied Mechanics, held at the Sorbonne in Paris, during September 22–28, 1946, the International Congress Committee, under the sponsorship of which these congresses are organised, decided to create a more permanent organisation, in order to provide the possibility of carrying out activities in the interval between the congresses and of entering into co-operation with other international scientific bodies. This permanent organisation adopted the name of "The International Union of Theoretical and Applied Mechanics". In agreement with the policy followed with respect to the international congresses for applied mechanics, the structure of the new Union thus far has been kept as simple as possible; a council has been elected, consisting at present of thirty members, and a secretary has been nominated for carrying out correspondence. The Council is the executive body of the Union; its members are persons actually engaged in scientific work (theoretical or experimental) in mechanics or in related sciences. The number of members of the same nationality must not in general exceed four; in certain cases a few extra members can form part of the Council, without being representatives of a particular country.

It is hoped that national organisations concerned with scientific work in applied mechanics and already in existence in various countries may be willing to enter into relationship with the International Union. The statutes of the latter have therefore been so framed that it will be possible to admit national organisations (or a national union of such, if there are more than one in the same country) as adhering organisations of the International Union. Any such national organisation (or union) can apply to have a representative on the Council. Organisations interested in co-operation with the International Union are invited to communicate with the representatives for their country.

Now that the draft statutes have obtained the required number of votes, the International Union is formally constituted. It will seek admission as an organisation adhering to the International Council of Scientific Unions.

Members of Council are at present: (*Belgium*): L. Baes (Brussels), F. H. van den Dungen (Brussels); (*Bulgaria*): K. Popoff (Sofia); (*China*): P. Y. Chou (Peiping), Y. H. Ku (Shanghai); (*Denmark*): J. Nielsen (Copenhagen); (*France*): A. Caquot (Paris), J. Pérès (Paris), H. Villat (Paris); (*Great Britain*): S. Goldstein (Manchester), R. V. Southwell (London), G. I. Taylor (Cambridge); (*Netherlands*): C. B. Biezeno (Delft), J. M. Burgers (Delft), C. Koning (Amsterdam); (*Norway*): J. Solberg (Oslo); (*Poland*): M. T. Huber (Gdańsk-Wrzeszcz); (*Sweden*): W. Weibull (Bofors); (*Switzerland*): J. Ackeret (Zurich), H. Favre (Zurich); (*Turkey*): Kerim Erim (Istanbul); (*United States*): H. L. Dryden (Washington, D.C.), J. C. Hunsaker (Cambridge, Mass.), Th. von Kármán (Pasadena, Cal.), S. P. Timoshenko (Palo Alto, Cal.); (*U.S.S.R.*): S. A. Christianovitch (Moscow), A. N. Kolmogoroff (Moscow), E. L. Nicolai (Leningrad). Extra members are: R. von Mises (Cambridge, Mass., U.S.A.); H. U. Sverdrup (La Jolla, Cal., U.S.A.).

The secretary for the present period is Prof. J. M. Burgers, van Houtenstraat 1, Delft, Holland.

It has been decided to accept the invitation of the Imperial College of Science and Technology, South Kensington, London, S.W.7, to hold the seventh International Congress for Applied Mechanics in its buildings during September 5–12, 1948.

THE EGYPTIAN ACADEMY OF SCIENCES

THE number of scientific workers in Egypt has increased considerably since the foundation of the Faculty of Science of the Fouad I University at Cairo in 1925. This has been accompanied by the development of a number of societies dealing with various branches of science, among which special mention may be made of the Société Entomologique d'Égypte, with its fine series of *Bulletins* and *Mémoires* dating from 1907. There has arisen also a demand for some institution where scientific specialists could meet and exchange ideas, for the famous Institut d'Égypte, founded by Napoleon, covers too wide a range of interests to meet these requirements. Accordingly, a group of nine Egyptians representing different branches of science met together in 1944 and founded an Egyptian Academy of Sciences, with Prof. Mohamed Khalil Bey as its secretary. The main objects of the new Academy are to stimulate a wider interest in science in general, and lead to more co-operation between men of science and a better co-ordination of their efforts.

The first volume of the *Proceedings* for 1945, published in 1946, has just been received, and comprises six articles dealing with biological subjects. All are written in English, but full abstracts in Arabic are included.

The first article, by the editor, Prof. K. Mansour, is devoted to an account of the Zooxanthellæ, and the food and feeding habits of the Tridacnidæ, in which the author attributes the large size reached by these lamellibranchs to their efficient feeding mechanism, and capacity of sieving huge quantities of water. The following article by Dr. J. J. Mansour-Bek deals with the digestive enzymes of *Tridacna elongata* and *Pinctada vulgaris*. In both papers the views of Prof. C. M. Yonge and others, as to the importance of intra-cellular digestion in these lamellibranchs, are strongly criticized. Prof. Y. S. Sabet describes the reaction of *Citrus mycorrhiza* to manurial treatment, and Z. Ahmed the effect of some environmental conditions on the growth and alkaloidal content of *Hyoscyamus muticus*. The nervous control of melanophores in the Egyptian chameleon is the subject of an interesting communication by Dr. A. M. Farghaly, and finally Dr. H. Said discusses the reaction of cotton, beans and other plants to colchicine treatment.

The difficulties attending publication in a foreign language have resulted in an unduly large number of printer's errors, but these do not affect the general standard of the *Proceedings*. Men of science in other countries will welcome the appearance of this publication and wish the new Academy every success. The *Proceedings* can be obtained either by exchange of corresponding publications, or by subscription (one Egyptian pound per annum). Communications should be addressed to the Hon. Secretary, Dar el Hikma, 42 Kasr Aini Street, Cairo, Egypt. E. HINDLE

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Monday, June 9

University College, London (at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Prof. Kapp: "The Presentation of Technical Information", Second Series, 2: "The Part Played by Psychology in Presentation".*

Tuesday, June 10

Medical Research Council (at the Royal Institution, 21 Albemarle Street, London, W.1), at 5 p.m.—Prof. Robley D. Evans: "Applications of Radio-active Isotopes in Biological Research".*

Royal Anthropological Institute (joint meeting with the International African Institute, at 21 Bedford Square, London, W.C.1), at 5.30 p.m.—Dr. S. F. Nadel: "Shamanism in the Nuba Mountains".

Wednesday, June 11

Manchester Statistical Society (at the Reform Club, King Street, Manchester), at 5 p.m.—Annual General Meeting.

Institute of Petroleum (at Manson House, 26 Portland Place, London, W.1), at 5.30 p.m.—Dr. A. C. Healey and Dr. L. Ivanovszky: "Petroleum Products in the Printing Ink and Allied Industries".

Thursday, June 12

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Mr. E. B. Verney, F.R.S.: "The Antidiuretic Hormone and the Factors which Determine its Release" (Croonian Lecture).

Friday, June 13

Institute of Economic Engineering (at Cowdray Hall, 1a Henrietta Place, London, W.1), at 7 p.m.—Mr. R. Cecil Smart: "Research and Expansion in Industry".

Sunday, June 8—Friday, June 13

Institution of Mechanical Engineers (at Storey's Gate, St. James's Park, London, S.W.1).—Centenary Celebrations.

Saturday, June 14

Institute of Physics, Electronics Group (in the Fyvie Hall, The Polytechnic, 309 Regent Street, London, W.1), at 2.30 p.m.—Discussion on "Thermionic Emission from Oxide-Coated Cathodes" (to be opened by Dr. F. A. Vick, Mr. D. A. Wright and Mr. A. J. H. Darlaston).

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant Registrar—The Secretary, Imperial College of Science and Technology, Prince Consort Road, London, S.W.7 (June 13).

Lecturer in the Engineering Department of the County Technical College, Wednesbury—The Director of Education, Dept. F.E., County Education Offices, Stafford (June 14).

Chief Metallurgist (temporary) to take charge of extensive chemical, metallurgical and testing laboratories at the Royal Ordnance Factory, Patricroft, near Manchester—The Ministry of Labour and National Service, Technical and Scientific Register, Room 171, York House, Kingsway, London, W.C.2, quoting F.388/47A (June 14).

Chemists (temporary) in the Department of Atomic Energy, Springfields Factory, Preston—The Ministry of Labour and National Service, Technical and Scientific Register, Room 171, York House, Kingsway, London, W.C.2, quoting F.389/47A (June 14).

Experimental Assistants (II and III, temporary) in the Department of Atomic Energy, Springfields Factory, Preston, under the Ministry of Supply—The Ministry of Labour and National Service, Technical and Scientific Register, Room 171, York House, Kingsway, London, W.C.2, quoting F.390/47A (June 14).

Lecturer in Mathematics and Mechanics—The Principal, Willesden Technical College, Denzil Road, London, N.W.10 (June 14).

Lecturer in Philosophy in University College, Dundee—The Secretary, The University, St. Andrews (June 15).

Senior Lecturer, and a Lecturer, in Natural Philosophy—The Secretary, The University, Aberdeen (June 20).

Senior Assistant in the Mathematics Department, a Lecturer in Chemistry, and a Lecturer in Geology and Biology—The Principal, Derby Technical College, Normanton Road, Derby (June 21).

Lecturer and an Assistant Lecturer in Organic Chemistry, and a Lecturer and an Assistant Lecturer in Physical Chemistry—The Secretary, King's College, Strand, London, W.C.2 (June 21).

Lecturer in Engineering at Peterborough Technical College—The Chief Education Officer, Education Offices, Town Hall, Peterborough (June 21).

Chair of Psychiatry—The Secretary, The University, Edmund Street, Birmingham 3 (June 28).

Research Fellowship (Organic Chemist to conduct research in problems relating to child health)—The Secretary, Institute of Child Health, Hospital for Sick Children, Great Ormond Street, London, W.C.1 (June 30).

Principal Scientific Officers: (*a*) Physicist to lead and direct research in problems of heat transfer in and as the result of fires, and (*b*) Physical Chemist to take charge of work on various problems of combustion and the suppression of fire by chemical means—The Secretary, Civil Service Commission, 6 Burlington Gardens London, W.1, quoting No. 1911 (June 30).

Superintending Chemical Engineer in the Chemical Research and Development Department of the Ministry of Supply—The Secretary, Civil Service Commission, 6 Burlington Gardens, London, W.1, quoting No. 1902 (June 30).

Lecturer in Agriculture (Crop Husbandry), and an Assistant Lecturer in Agricultural Botany—The Registrar, University College of Wales, Aberystwyth (June 30).

Lecturer in Chemistry and Soil Science, at Trinidad—The Secretary, Imperial College of Tropical Agriculture, Grand Buildings, Trafalgar Square, London, W.C.2 (June 30).

Assistant Lecturer in Geology—The Registrar, University College, Cathays Park, Cardiff (June 30).

Head of the Pharmacy Department—The Principal, Heriot-Watt College, Edinburgh (June 30).

Deputy Government Chemist in Jamaica—The Director of Recruitment (Colonial Service), 15 Victoria Street, London, S.W.1 (June 30).

Assistant Lecturer, and Demonstrators (3), in the Department of Anatomy—The Registrar, University College of South Wales, Cathays Park, Cardiff (June 30).

Lecturer in Mechanical Engineering—The Registrar, Merchant Venturers' Technical College, Unity Street, Bristol 1 (June 30).

Principal of the new Technical College to be established at Grantham—The Director of Education, County Offices, Sleaford, Lincs. (June 30).

Lecturer (Grade II) and an Assistant Lecturer (Grade III) in the Department of Applied Mathematics—The Registrar, The University, Liverpool (July 1).

Senior Research Officer or Research Officer, Section of Meteorological Physics Research, Melbourne—The Secretary, Australian Scientific Research Liaison Office, Australia House, Strand, London, W.C.2, quoting No. 1291 (July 7).

University Lecturers and University Demonstrators in Engineering—The Secretary, Appointments Committee, Engineering Laboratory, Cambridge (July 7).

Henry Bell Wortley Chair of Metallurgy—The Registrar, The University, Liverpool (July 7).

Professor of Mathematics, a Professor of Physics, a Senior Lecturer in Mathematical Physics, and a Senior Lecturer in Physics, at the University of Otago, Dunedin—The High Commissioner for New Zealand, 415 Strand, London, W.C.2 (July 15).

Lecturer in Botany, a Lecturer in Zoology, a Lecturer in Chemistry, and an Assistant Lecturer in Mathematics, at the University of Otago, Dunedin—The High Commissioner for New Zealand, 415 Strand, London, W.C.2 (July 31 in New Zealand).

Fuel Engineer and Assistant Fuel Engineer (male) under the Ministry of Fuel and Power—The Director of Establishments, Ministry of Fuel and Power, 7 Millbank, London, S.W.1 (July 31).

Lecturer in Mechanical Engineering at the Chance Technical College—The Chief Education Officer, 215 High Street, Smethwick.

Science Lecturer in the Department of Bakery and Confectionery—The Principal, Borough Polytechnic, Borough Road, London, S.E.1.

Crop Recorder, and an Assistant Seed Production Officer—The Secretary, National Institute of Agricultural Botany, Huntingdon Road, Cambridge.

Registrar—The Principal, Huddersfield Technical College, Huddersfield.

Electronics Technician to undertake development, construction and maintenance work on electronic apparatus for medical use—The House Governor and Secretary, General Infirmary, Leeds.

Chemists (men and women) for temporary appointments in the Chemical Inspection Department, Ministry of Supply—The Ministry of Supply, Est. 5 (B) 2, Room 828, Adelphi, London, W.C.2, quoting Chem/65.

Graduate Research Assistant for experimental work on nuclear physics, mainly by cloud-chamber methods—The Professor of Physics, University College, Aberystwyth.

Lecturer (preferably recent Ph.D.) in field of nuclear physics, in the Department of Physics, Queen's University, Kingston, Canada—Principal R. C. Wallace, 15 Mays Hill Row, Shortlands, Bromley, Kent.

Laboratory Assistant (bacteriological, Grade B)—The Secretary, National Institute for Research in Dairying, Shinfield, Reading, Berks.

SCIENCE AND THE HUMANITIES IN THE UNIVERSITIES

THE debate on university education in the House of Lords on May 14 was noteworthy for an important speech by the Lord Chancellor, Viscount Jowett, and for a contribution by Lord Cherwell which men of science should find of special interest. Lord Cherwell, in a cogent argument dealing with the dangers of central control of the universities, made a plea for the safeguarding of their autonomy in the increasing dependence of the universities on the Government for financial support; and he urged again the vital importance of not divorcing research from teaching, or teaching from work on the frontiers of knowledge. Speaking of the importance of the student having an opportunity of both studying the advance of knowledge and having it expounded and explained by those who were themselves working on the frontiers of knowledge, Lord Cherwell formulated admirably the function of a university teacher. This, as he sees it, is to develop in young people the habits of exact and logical thought, to show them how and where the underlying facts can be ascertained on which our conclusions are to be based, to indicate to them how the great minds of the past have tackled problems, to show what conclusions they have reached and how they have justified them; and, above all, to arouse the students' curiosity and interest and to stimulate them to spend laborious days and nights in an effort themselves to contribute something towards the advance of knowledge.

That is a fine ideal which must be kept in mind as we seek to formulate more specifically, as was urged in the recent British Association Conference held at Manchester (see *Nature*, May 24, p. 698), our ideas as to a general education for scientific workers. A further contribution to that end is to be found in a discussion of the relations between science and the humanities to which the greater part of the current issue of *The Universities Quarterly** is devoted. In that discussion, as in his speech in the House of Lords, Lord Beveridge makes a powerful plea that the social sciences should indeed be regarded as sciences and not as a branch of the humanities. They should be placed in their right relation to the other sciences, studied and taught not in isolation but together, and those who devote their lives to these studies should practise emotional detachment—above all from political controversies and the organisation of parties. This conviction leads Lord Beveridge to the view that the establishment of a science of human society should now have first call on all our resources and effort; and consequently such sciences should receive in full measure the material means they require for their development as sciences of observation and not as arts. This would in turn necessitate a manifold increase in the number of permanent posts in the faculties of social science of British universities, where teaching and research can be combined and where also the material means of research are available, especially statistical laboratories and provision for the training of field workers. As he did in the House of

---

* Turnstile Press, 10 Great Turnstile, London, W.C.1.

Lords debate, Lord Beveridge here also suggested that the building up of the social sciences would make a valuable contribution towards preventing war and other misuses of natural science. He urged frankly that the leaders of natural science should favour the devotion of more money to social science, even if it meant less for natural science, and they should also realize that the social sciences are not the same as the natural sciences.

Sir Richard Livingstone discusses the need for a wider outlook in his contribution in *The Universities' Quarterly*. He recognizes it is necessary to see that both humanists and scientists, while specializing in their own subjects, at the same time receive the wider education which they need as men and citizens. Every educated man should understand the impact of science on civilization, and its place in civilization ; but the man of science also needs a wider education than science itself can give. What the world most needs to-day is a clear and worthy view of life. To this end Sir Richard suggests that moral philosophy should be a compulsory subject in universities, together with either logic or the theory of knowledge, and that it should be possible, but not compulsory, for everyone to take religion and the history of science in his or her degree course.

While Sir Richard Livingstone pleads for a return to the Greek attitude to life, Prof. J. D. Bernal, urging the establishment of closer relations between science and the humanities, suggests that we need an integration of the scientific and humanistic points of view, and that we should seek to join these two streams of human culture. He welcomes a plea put forward by Prof. Dobree for a common basis of knowledge, but he believes there would still be the need for faculties of arts and of science, differing in the emphasis given to different parts of the common basis. Prof. Bernal suggests that our presentation of whole subjects such as physics requires simplifying and should be accompanied by more interpenetration and also by active personal collaboration ; and he goes so far as to urge that the union of science and the humanities is a condition of survival.

Some of these ideas are to be found also in the fine presidential address "Classics and the Social Revolution of our Time" delivered by Lord Greene, the Master of the Rolls, to the Classical Association last April. Lord Greene urged that one of the principal allies in the defence of humanities is science itself. A race that knows and cares for nothing but science and its practical applications would, if left to itself, become as soulless and mechanical as the formulæ that it invents and the engines that it creates ; just as a race that knew and cared for nothing but the humanities would end its life in dreams or in some cloister of the mind. Neither the perfect scientist nor the perfect humanist, he believes, can hope to reach human perfection. Scientific men are conscious of the weakness in the educational system which leads to their growing up ignorant of the humanities, and students of the arts ignorant of science. He therefore thinks that the danger would largely be averted if all education, before specialization claims the pupil, were to include at least the rudiments of training in the value of honest thought, of a fair but critical mind and of the beauties of literature and art.

This recognition of the cultural values of science, and the attempt to formulate specifically, if tentatively, our ideas as to a general education not merely for scientific workers but also for all other university students, coming from such diverse quarters, are welcome evidence that the problems of university expansion are being faced with vision and imagination as well as realistically. That this is so is shown further by the Lord Chancellor's speech in the House of Lords. Lord Jowett spoke immediately after a well-balanced speech by Lord Lindsay of Birker to which reference was made in *Nature* of June 7, p. 755. Lord Lindsay also referred to the place of the universities in meeting the demand for refresher courses, and to the importance of their extra-mural work and particularly their part in adult education. In this extra-mural work for further education, as well as in their internal aims, the universities will find considerable scope for pressing the study of the humanities, especially in so far as they are, or should be, correlated with the sciences.

ADVENTURES AND DISCOVERIES IN ARMY EDUCATION

Adult Education

The Record of the British Army. By Major T. H. Hawkins and L. J. F. Brimble. Pp. viii+420. (London : Macmillan and Co., Ltd., 1947.) 15*s*. net.

IN 1940 it might well seem that "education was the first casualty". Yet, as in the First World War, it was already arising with new vitality, phœnix-like, from the consuming flames. The shape of things to come in Mr. Butler's Education Act was beginning to appear. More immediately, the educational resources of the whole of Britain had been mobilized, through the Central Advisory Council for Education in H.M. Forces and its twenty-three regional committees, to provide mental stimulus and sustenance for the men and women who were being transformed into citizen soldiers, sailors and airmen. In the autumn the members of the Army Educational Corps were brought back from the 'other duties' to which they had been posted, and an immense educational enterprise had been launched with the enemy literally knocking at our gates. Amazing in itself, no effort and adventure on this scale would have been possible in peace-time. But how much was actually done, and what are likely to be the enduring fruits of this enormous experiment in further education ?

This attractive and impressive book is the first full-scale account and assessment of 'Army education' during the War and the release period. The authors had first-hand knowledge of the scheme in action. They are experienced in research. There is not a dull chapter in what they have written. The story is told with admirable clarity, balance, discrimination, and humour. It is neither arid in detachment nor vitiated by prejudice and partisanship. It is extraordinarily well documented, and it is set in the framework of a wide acquaintance with adult education in civil life. The suggestions concerning the application of what Army education has taught us to what the Education Act envisages are well considered and constructive.

To generalize, either appreciatively or critically, on this book of four hundred closely packed pages would be foolish. To particularize would take pages instead of paragraphs. It must suffice to touch upon a few typical points.

The opening chapter is a fascinating record of adventures and activities in Army education from 1747 onwards. Not solely for war-time achievements has the Army Educational Corps now been honoured by the prefix Royal.

The volume and variety of those achievements cannot even be summarized here. Before the Army Educational Corps lay an opportunity such as the civilian bodies have never had—millions of men and women organised into compact units, stimulated to a new interest in the world about them, wanting to keep contact with the unregimented life which previously had bored them, anxious to prepare for a new start 'after the War', and with leisure which they had few means of occupying in satisfying ways. Moreover, there were representatives of every trade and profession (including teachers) available to play the part of 'instructors'. But what should be the aim ? Some (too many) commanding officers said "Morale !", and had no further use for education. But while no sensible man could question the primacy of morale in an army fighting all over the world, or the importance of education in promoting it, throughout the War "Army Education deliberately and consistently sought to provide the means for all of developing their talents as individuals, as citizens, and as breadwinners". The Army Educational Corps tried all ways and all means. If the Army Bureau of Current Affairs tended to make too much of 'discussion-method', it also developed great skill and ingenuity in making and using pictorial, mechanical, and dramatic aids. The chapters on 'Basic Education' and on the A.T.S. reveal the adaptability of administrators and instructors to special needs. Though inevitably much of the work had to be superficial and transient, the Army Educational Corps discovered the art of 'persuasive presentation', practised 'ice-breaking methods', and, as time went on, made increasing use of intensive courses, often residential.

The Corps were ready to learn. This book is full of references to civilian co-operation not only in supplying lectures and teachers or providing courses, but also by contributing advice and suggestions matured by long experience in many forms of adult education. It was sometimes said that the only place where the command education officers of the three Services met for consultation and conference was at the periodical meetings of the regional committees. There were, of course, mutual criticisms, but there was and is a genuine comradeship in a common enterprise.

If the authors of this book had been as closely acquainted with Central Advisory Council records as with those of the Army they would perhaps have been still more even-handed in their narrative and their evaluation. The story from the Central Advisory Council angle will be told elsewhere. Meantime, there are some passages here that need correction. The reference, for example, to civilian lecturers who had to be dropped is rather misleading. Every civilian lecturer was pledged to avoid propaganda. The actual number of offenders was very small, and some of these on inquiry proved to be sinned against, not sinning: 'security' was on occasion made an excuse for prejudice. When Army officers were ordered not to discuss the Beveridge Report officially with their men, because it was still *sub judice* in Parliament, the Secretary of State for War told a protesting House that all was well, for regional committee lecturers were dealing with it, and could be trusted to be impartial. Mr. W. E. Williams' humorous exaggeration about the efficiency of civilian lecturers was, of course, not meant as a serious judgment, and when unit officers were clamouring for a lecture, no matter on what or by whom, each week, regional committees were tempted, or driven, to use 'amateurs'.

Too little is said in the book about the constant plea of regional committees for more sustained work and fewer fugitive lecturers. There is practically no reference to the stream of Central Advisory Council lecturers sent overseas after hostilities ceased, though the distinguished Commander-in-Chief, Middle East, who first opened the door, said recently that they saved the situation, *because* they were civilians, not in uniform, fresh from home, speaking with some authority on their subjects but also with complete freedom.

The work goes on. In their chapter, "Comments and Criticisms", the authors point to the possibilities of great developments both in Army education and in civil life. Their book will long be a valuable aid to those on both sides who believe that there is 'no end to learning', especially from experience, and it will ensure that a unique body of experience is not forgotten.

BASIL A. YEAXLEE

CATALYSIS

La théorie de la catalyse vue d'ensemble et essai de synthèse

Par Prof. Jacques Métadier. (Actualités scientifiques et industrielles, 1005.) Pp. 101. (Paris : Hermann et Cie., 1946.) 200 francs.

THE definition of the word 'catalyst' used to have a quite precise meaning in chemistry, whether catalysis occurred in heterogeneous or homogeneous systems. In recent years 'catalysis' has come to include a tremendous variety of chemical reactions which, strictly speaking, do not involve true catalysis at all. In a similar way, the term 'negative catalysis' did duty until such time that the mechanism of the retardation and inhibition of chemical reactions was more fully understood, when it became abundantly plain that the inhibitor was almost invariably chemically destroyed in the inhibitory reaction. This extension of the meaning of the term has therefore led to the belief that a systematic treatment of the mechanism of chemical reactions is most easily accomplished by treating reactions as catalytic processes.

There is, of course, an element of logic in this attempted classification that arises in the following way. The more the subject of chemical kinetics advances the more it becomes evident that the existence of simple bimolecular reactions is comparatively rare, and that, in fact, most reactions seem to be complex in the sense that the reactants in a system cannot be induced to react unless some body, either derived from the reactants themselves or purposely added, is present to start off reaction. Sometimes that body is regenerated as in chain processes; but this is not always necessary. Furthermore, in the majority of such complex reactions of the homogeneous type there is little doubt that although on the surface catalysis appears to take place, the catalyst is actually chemically consumed during the operation. The question to be decided is whether it is legitimate to extend the term 'catalysis' to all such cases. Prof. Métadier decides for this extension, and consequently cites in his survey a great variety of homogeneous and heterogeneous and even enzymatic reactions where it is difficult to say whether heterogeneous or homogeneous process operates. There is, however, much to be said against this classification. It would be more satisfactory to treat the matter upon the basis of chemical kinetics on which everything rests and to discuss on its merits each type of reaction.

This book, therefore, is a review of chemical kinetics in a compact form. Formal chemical kinetics are briefly surveyed with appropriate definitions of reaction velocity coefficients, and there is a short account of the elements of the quantum theory of reactivity without going into the details of the transition state treatment. Then follows the systematic treatment based not on specific reactions but on types of catalysis, namely, homogeneous catalysis, physical catalysis, heterogeneous and negative catalysis, catalysis by colloids and biological catalysis. Each subject is a vast domain in itself; and therefore only very brief descriptions can be given of suitable examples in these several fields without going into any critical discussion of the data. There are, unfortunately, no references, so that the inquiring reader cannot pursue the matter further. The reviewer feels, however, that the time has come when such an extension of the scope of catalysis is practically impossible and is perhaps now undesirable.

H. W. MELVILLE

A GERMAN VIEW OF THE ATOM BOMB

Die Geschichte der Atombombe

Mit einer elementaren Einführung in die Atomphysik auf Grund der Originalliteratur gemeinserständlich dargestellt. Von Hans Thirring. (Wissenschaft für Jedermann.) Pp. 150. (Wien: Neues Österreich Zeitungs- und Verlagsgesellschaft m.b.H., 1946.) n.p.

PROF. THIRRING was dismissed from the chair of theoretical physics in the University of Vienna by the Nazis because of his democratic views and his association with anti-militaristic movements, was persecuted by the Gestapo, and was reinstated only after the downfall of the Nazi regime. The author certainly is well qualified politically to interpret the significance of atomic energy in a popular book to a German-speaking public. The reviewer considers that Thirring has admirably succeeded in the task he has set himself. The book provides an elementary introduction to the structure of the atom and the nucleus, a history of the attempts in the Allied countries (on the basis of the Smyth Report) and in Germany to make use of atomic fission, and a short evaluation of the political aspects of atomic energy. The book is written in a clear and fresh style enlivened by sarcastic remarks against the treatment of science under Nazism.

The author stresses the necessity of an expe counteracting the fantastic rumours circulating i Central Europe: "There were people who claime to know that the whole atom bomb business w nothing but a bluff . . . again others thought th Americans had been enabled to build the bomb onl by the booty of knowledge and material captured i the conquest of Germany, and it was stated th German inventions had been surrendered to Englan and America by traitors. Thus the old *Dolchstos legende* of 1918 has been revived in a modified shape. It is argued that the advantage of the Allied countries over Germany in the development of atom energy has been primarily intellectual and moral, an only secondarily material and financial. On on hand, the influence of the Nazi physicists Lenar and Stark, who struggled for 'German' as oppose to 'Jewish' physics, prevented Germany fro keeping abreast of the scientific developmen abroad; Hugo Dingler, a philosophical protagonis of the Lenard–Stark tendency, is quoted as havin ridiculed the possibility of a conversion of mass int energy as a "product of an extravagant imagination as late as 1941. On the other hand, Thirring state that many of the best, notably Hahn and Laue, wer quite clear that it would be a crime against mankind to supply the psychopath Hitler with an ato bomb. The net effect was that the Allies were fa ahead of Germany even before the full materi resources of the United States were mobilized for th atom bomb in 1942.

A very large volume of factual material i marshalled successfully by the author, and th small number of errors is surprising. On p. 8 on would like to see mention of Corson, Mackenzi and Segrè, who made element 85 artificially befor Karlik and Bernert announced its discovery as rare branching product of the natural radioactiv series. The reference to the work of Pettersson Stetter and Kirsch (p. 48) strikes the reader as odd Faraday is erroneously associated with Cambridg (p. 54). The paper in *Nature* by Dodé, Halba Joliot and Kowarski, which dealt with the neutron emitted in fission, was preceded by a paper by Halba Joliot and Kowarski, in which the large-scale emission of neutrons was first established (p. 81). Th slowing down of neutrons to thermal energies b pure uranium (p. 86) is scarcely a practical proposition. Chain reactions based on unidentifie natural α-ray emitters (p. 138) do not appear likel

Thirring expresses reasoned optimism concernin the peaceful utilization of atomic energy. Furthe a stimulating discussion of the possibilities of man made explosive nuclear chain reactions, not involvin fission, but requiring ignition by fissile material, i given. The ${}^{2}_{1}D(d,n){}^{3}_{2}\mathrm{He}$ and ${}^{7}_{3}\mathrm{Li}(p,\alpha){}^{4}_{2}\mathrm{He}$ reactions ar mentioned. These possibilities make the task of th establishment of permanent peace based on understanding even more pressing. Quoting Roosevelt an Einstein, the author takes the opportunity to urg the adaptation to this task of our educational systems, and refers to his book soon to be published o "World Peace as a Psychological Problem", in whic he concludes—though he does not blame Americ for having used the bomb in the War: "Whoeve believes in the future of mankind . . . must b imbued with the conviction that man can be taugh that . . . those who triumphantly throw the ato bomb in the last analysis only harm themselves".

E. BRODA

Marine and Air Navigation

By John Q. Stewart and Newton L. Pierce. Pp. xii + 472. (Boston, New York and London: Ginn and Co., 1946.) 26*s*. 6*d*. net.

Coasts, Waves and Weather

For Navigators. By John Q. Stewart. Pp. vii + 348. (Boston, New York and London: Ginn and Co., 1946.) 21*s*. net.

THESE two volumes are typical of publications popular in the United States, but not seen often in Britain. The American reading public evidently appreciates books upon technical subjects, written in sufficient detail to make a volume of appreciable size, but using popular language rather than the more concise and pointed style of the text-book. Such books have their value to the student, and should be of great use for introductory reading. In Britain we seldom see this kind of work. A popular book on a technical subject, in Britain, is usually so small that only the broadest treatment is possible, which, although correct in substance, is not much use to even an elementary student.

"Marine and Air Navigation" covers the whole subject, so far as it can be treated in the classroom, with many clear explanatory diagrams and photographs. The style is empirical, but a wealth of information of use to the navigator is given. Celestial navigation is covered without unnecessary astronomical detail, and some useful coloured "Star Charts" are included. Various maps and tables naturally refer to the American continent in general, and references are almost entirely to American publications, some of which are, however, obtainable in Britain.

"Coasts, Waves and Weather" is a fascinating book for general reading, but is rather the more non-technical of the two. It is not, in any sense, a text-book on meteorology, as its title might suggest. Part 3, "Meteorology for Navigators", treats the subject from the point of view of weather forecasting by the man flying or sailing into it, and does this very thoroughly with the aid of some beautiful cloud pictures. Again, the description and examples of coast-lines, terrains, and oceanography are taken from the American continent, and lose a certain local interest for British readers.

Both books are well worth reading, the few strictly American terms are generally understandable from the sense of the text, and the style of the writing never becomes pedantic. They might be read with interest and advantage by both sailors and airmen, professional and amateur.

Atoms, Stars and Nebulæ

By Leo Goldberg and Lawrence H. Aller. (Harvard Books on Astronomy.) Pp. v + 323. (London: J. and A. Churchill, Ltd., 1946.) 18*s*.

ONE of the most serious defects in astronomical literature is the lack of any authoritative and up-to-date English text-book on astrophysics. The need for such a book is widely felt. This book is not a text-book and it does not deal with all branches of astrophysics, but it partly fills the gap. That it has met a real need is shown by the fact that the present edition is the third reprint since it was first published in 1943. In this reprint various additions have been made to bring the book up to date.

The volume begins with a non-mathematical account of the principles of atomic physics and the theory of light. It then goes on to consider stellar atmospheres, the widths of spectral lines, the formation of absorption lines, the curve of growth, the differences between the spectra of giant and dwarf stars of the same spectral type and related problems. Special classes of stars are then considered: pulsating stars, novæ, planetary nebulæ, and stars with extended atmospheres. One chapter is devoted to the interstellar gas, and a final chapter deals with the source of stellar energy. Several appendixes give much useful information.

The book forms one of the excellent series of Harvard Books on Astronomy. Like all the other volumes of this series, it is very well illustrated. It can be strongly recommended to the student of astrophysics as an authoritative introduction to the subject; it is also a useful reference book for the working astronomer.

Science, Faith and Society

By Prof. M. Polanyi. (University of Durham: Riddell Memorial Lectures, Eighteenth Series.) Pp. 80. (London: Oxford University Press, 1946.) 2*s*. 6*d*. net.

THE Riddell Memorial Lectures, given by distinguished men of science, philosophy and theology, provide a pulpit of great value. One has only to glance through the list of names since the first series was published in 1928 to see how powerful this foundation has become. Into this learned company Prof. M. Polanyi fits extremely well. He discusses "Science and Reality" (1), "Authority and Conscience" (2), and "Dedication or Servitude" (3). There is also an appendix dealing with the premises of science and the question of observation. Through all that Prof. Polanyi has to say shines a passionate desire for truth and for full opportunity to realize it. His background, differing—as it must—from our own in certain ways, is at one with it in its plea for tolerance, and for the inculcation of responsibility in the transmission of tradition. By means of a clarification of man's cultural and social purpose, he will be brought—it is claimed—to a revelation of the Divine.

An interesting point is made regarding seeming irrelevance. Scientific genius consists largely in the ability to pounce upon something fundamental and to follow it up relentlessly, consigning the rest to limbo. Indeed, this is the way to the eternal verities, philosophic and otherwise. F. IAN G. RAWLINS

Population, Psychology and Peace

By J. C. Flugel. (Thinker's Library, No. 117.) Pp. xviii + 142. (London: Watts and Co., Ltd., 1947.) 2*s*. 6*d*. net.

IN this book, Dr. Flugel analyses with acumen the emotional resistances to accepting the doctrine of Malthus, and appears to come down on the side of neo-Malthusianism. His psychological approach is novel and puts into perspective the economic and quantitative aspects of the subject which tend to dominate current discussion. But the calm tone and reasoned exposition conceal many controversial issues. How much truth is there, for example, in his key premise (p. 103) that "the decreasing poverty of the western world is due in considerable measure to the reduction of the birth rate"? Is it true (p. 47) the 'elderly' contribute more to the community and make fewer demands on it than do young children? Nevertheless, the book will be read with much profit by students of demography in general and by members of the Royal Commission on Population in particular. Dr. Joad contributes a lively introduction.

JOHN COHEN

SOME NEW ASPECTS OF MITOTIC POISONING

By Dr. PIERRE DUSTIN*

(From the Chester Beatty Research Institute, The Royal Cancer Hospital (Free), London, S.W.3)

A PROPERTY of many chemical compounds, both organic and inorganic, is to disturb or destroy cells during cell division or when division is about to begin. Two well-known examples are colchicine, which arrests mitosis at metaphase by depriving the spindle of its normal properties, and trypaflavine (3 : 6-diamino-10-methylacridine hydrochloride), which prevents the onset of prophase and leads to extensive nuclear and cellular degeneration[1]. There are undoubtedly close relations between these two types of activity, since colchicine induces in the lymphoid tissues of mammals extensive damage similar to that which led to the discovery of the properties of trypaflavine[2]. A great amount of work has been done on colchicine, following the observation of its polyploidy-inducing properties in plants[3], and numerous substances having similar effects on plant-cells have now been described[4]. Experimental work on mice recently pursued with the purpose of investigating the nature of the action of ethylcarbamate (urethane) on malignant growth[5] and in leukæmia in man[6] has led to the discovery of new mitotic poisons of comparatively simple chemical constitution[7]. This fact, and some other recent advances in this field, makes possible a fresh discussion of the mechanism of mitotic poisoning and of some recently proposed theories.

Mechanism of Nuclear Destruction by Pycnosis

It was the study of substances inducing extensive destruction of the lymphocytes in the spleen, the lymph-glands, and principally in the thymus, which led to A. P. Dustin's discovery of new mitotic or 'caryoclasic' poisons[1,2] and of the cytological effects of colchicine. This alteration of the lymphocyte, consisting of a sudden agglomeration of all chromatin structures in small spherical masses, is named 'pycnosis'. With mitotic poisons of the trypaflavine type, following a period of diminished mitotic activity, irregular Feulgen-positive masses are found in the germinative region of the intestinal mucosa in the mouse. It seemed necessary to re-investigate this last phenomenon, which had been considered by A. P. Dustin and his collaborators[8] as evidence of an intracytoplasmic synthesis of nucleoproteins.

In 1939, Zylberszac[9] found that hydroquinone and pyrocatechol very rapidly produced extensive changes in these intestinal crypts. I have recently studied such changes with various histological techniques (in particular, pyronine-methyl green staining for the nucleolus, and La Cour's[10] lacmoid smear method for the chromatin structures). With hydroquinone, which gives the clearest pictures in the shortest time, the effect is a nuclear degeneration closely resembling the 'pycnosis' observed in lymphoid tissue. The following stages can be identified (Fig. 1) : (1) considerable swelling (hydration) of the cytoplasm, giving the epithelial cell a spherical form ; (2) at the same time or very shortly after, alterations of the nuclear membrane ; (3) accumulation of the thymonucleic acid on the nuclear membrane, with disappearance of all microscopically visible chromosome structures, and fragmentation of the nuclear membrane ; (4) formation of a sphere composed of acidophil (basic) protein + ribonucleoprotein, the nucleolus persisting for some time, and the 'thymonucleic' material forming peripheric shell-like structures ; (5) rapid fragmentation of these pycnoses, with formation of numerous small particles, some Feulgen positive, some negative, the debris being engulfed in the cytoplasm of the surrounding cells (cf. A. P. Dustin[8]), and eventually eliminated towards the intestinal lumen (*'excrétion sphérulaire'*). Although the pictures are more difficult to interpret in lymphoid tissue, there are good reasons for believing that the same sequence of cellular changes precedes the phagocytosis of cellular debris by macrophages of reticular origin.

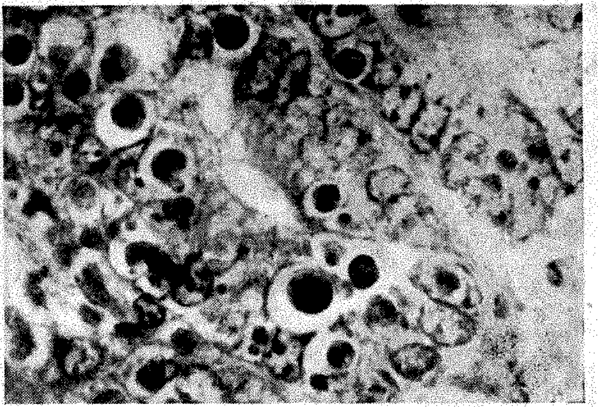

Fig. 1

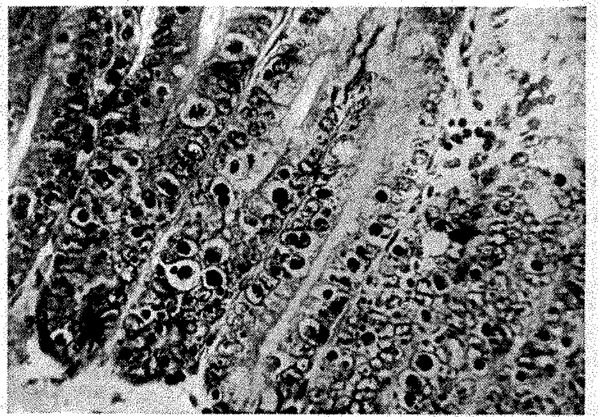

Fig. 2

NUCLEAR AND CELLULAR DESTRUCTION IN THE INTESTINAL CRYPTS OF THE MOUSE

Fig. 1, 4 hr. after 2·5 mgm. of hydroquinone.
Fig. 2, 10 hr. after 5 mgm. of sodium cyanate.

In the intestine, it is evident that such nuclear destruction only takes place in the region of active cellular proliferation, during or after a period of abnormally low mitotic activity. This leads to the conclusion that the cellular breakdown occurs when cells attempt to undergo mitosis. For this reason, one may name this phenomenon 'mitotic poisoning before prophase'.

This interpretation means that only cells which would have undergone division during the period of action of the poison are altered. This affords an explanation of the appearances seen in the intestinal crypts, but it is not so evident that it applies to lymphoid tissue. In spleen and lymph glands, the localization of pycnosis in the germ-centres, where most mitoses normally take place, does, however, point in the same direction; and in the thymus, where most mitoses are found in the cortical region, so too are the pycnoses. But here, the extent of the cellular destruction which may be found within less than twenty-four hours suggests that more cells are destroyed than would have divided in this period of time. Further quantitative study of the number of cells normally undergoing mitosis in the thymus is clearly necessary.

---

* Associé du Fonds National Belge de la Recherche Scientifique.

The thymic atrophy following on pycnosis was found by Selye to be a non-specific change induced by any sublethal action on the organism, the so-called 'alarm reaction'[11], and Selye, Leblond and others were able to demonstrate that the internal secretions of the adrenal cortex played a fundamental part in this cellular destruction[12]. An interesting fact quite recently discovered is that induced pyridoxine deficiency following the injection of desoxypyridoxine also produces extensive pycnotic degeneration in the thymus[13].

Carbamates and Cyanates

Until recently, few substances were known to affect division similarly to trypaflavine or hydroquinone, and most work had been devoted to substances modifying division in a manner similar to that of colchicine.

Ethylcarbamate (urethane) has now been found to modify the cellular divisions in the intestine of the mouse[7]. This action is much slower than that of hydroquinone, marked pycnotic destruction occurring only eight hours after the injection, and being still very conspicuous twenty-four hours later. At the same time the mitotic activity is abnormally low, and it seems clear that only the cells which should have divided are destroyed by ethylcarbamate. In thymus and lymphoid tissue, no evidence of mitotic poisoning is found after a single injection. Ethylcarbamate is thus a slow-acting mitotic poison with activity of the 'trypaflavine' type.

Investigation of other carbamic esters has so far shown that similar effects are produced by ethylphenylcarbamate, isopropylphenylcarbamate and β-chloroethylcarbamate. It is remarkable that methylcarbamate, even in big doses, does not interfere at all with mitosis in the mouse, and is without the narcotic properties of the other carbamic esters tested. Negative results obtained with ethyloxamate (oxamethane) and with the narcotic chloretone (known to affect mitosis in Urodele larvæ[14]) show that the action of carbamic esters has some specificity.

It seemed of interest to investigate other substances related to urethane and having similar effects. Cyanate was suggested by Dr. Schütz, following recent work on the hypnotic properties of sodium cyanate[15]. It was also suggested to me (by Dr. F. L. Rose) that cyanate and urethane may both enter in combination with amino groups following the reactions:

$$HCNO + NH_2R \rightarrow NH_2CO{-}NHR$$

$$NH_2{-}CO{-}OC_2H_5 + NH_2R \rightarrow NH_2CO{-}NHR + C_2H_5OH.$$

In mice, sodium cyanate was found to have cytological effects similar to those produced by urethane, and caused extensive pycnotic degeneration in the intestine (visible six hours after a single injection of 5 mgm.) (Fig. 2). In the germ-centres of splenic lymphoid tissue and in the cortical region of the thymus there is also marked cellular destruction by pycnosis, repeated injections leading to a complete destruction of the small cells of the thymic cortex. Thus cyanate is also a mitotic poison of the trypaflavine type, with greater toxicity and more powerful effects than ethylcarbamate. It was also found that potassium thiocyanate (5 and 10 mgm.) had a similar action, the intestinal pycnoses being very conspicuous, and lymphoid pycnoses less numerous than after the injection of cyanate. These results are interesting when compared with the findings of Barker, Lindberg and Wald[16], who noticed anæmia, and blood and bone-marrow changes "resembling benzene poisoning", in dogs given repeated injections of thiocyanate; this substance has been extensively used in the treatment of human hypertension[17].

In a recent review on mitotic poisons[18] I pointed out that similar substances may be formed within the organism. It has been suggested by Schütz that ammonium cyanate exists in thermodynamic equilibrium with urea and may be a normal constituent of the mammalian organism and play some part in the intoxication of uræmia:

$$NH_2.CO.NH_2 \rightleftharpoons NH_4.CNO.$$

It has been reported[19] that extensive pycnotic destruction of lymphoid tissue followed bilateral nephrectomy in the mouse. This experiment was repeated in order to decide whether the typical intestine changes found in cyanate poisoning existed also in this condition. In two mice which survived the operation for twenty-five and twenty-nine hours respectively, considerable destruction was found in the thymic cortex and in the splenic lymphoid tissue, but the intestinal mitoses were not at all affected. These experiments, which are somewhat similar to those of Selye[11], do not suggest that cyanate accumulates in the tissues as a consequence of acute renal failure. Cyanate is so far the simplest organic compound capable of poisoning mitosis, and its further study should be expected to throw more light on the chemical mechanisms involved.

'Nitrogen-Mustards'

The pharmacology and toxicology of the *bis*-(β-chloroethyl)-amines ('nitrogen-mustards') have been studied during recent years (Gilman and Philips[20], Dixon and Needham[21], and Rhoads[22].

These substances have a special toxicity for cells in division or about to divide, and their cytological action appears limited to the germinative layers. In a study of the action of methyl-*bis*-(β-chloroethyl)-amine on the divisions in the intestine and blood-forming organs of the mouse, the cytological changes were found to be identical with those observed after cyanate or ethylcarbamate poisoning, especially in the intestine, although the chloroethylamines differ from other mitotic poisons of the trypaflavine type in the comparatively small quantities (for example, 0·5 mgm./kgm. of body weight) which are effective. In rapidity the action on the intestine equals that of hydroquinone.

These results are of special interest in relation to work on the enzyme-inactivating properties of nitromustards and their possible poisoning of phosphokinases[21].

Arsenic and Dimercaptopropanol (*BAL*)

Following a paper by Wätjen[23], inorganic and organic arsenical derivatives were extensively studied in A. P. Dustin's laboratory by Piton[24]. They were found to have two possible actions: (1) destruction by pycnosis of lymphoid cells; (2) accumulation of numerous pathological mitoses arrested at metaphase. This last effect—identical with that of colchicine—was most apparent after the injection of cacodylate.

Thus arsenical compounds belong to the two groups of mitotic poisons previously defined.

The recent discovery of the remarkable detoxicating properties of dimercaptopropanol (*BAL* = British anti-lewisite[25], a specimen of which was kindly provided by Prof. R. A. Peters), suggested the following experiments, aimed at testing whether the mitotic poisoning by arsenite may be reversible. The metaphase-arrest was studied in bone-marrow preparations by the lacmoid technique[10]. It appeared that within one hour after the injection of sodium arsenite, most mitoses were stopped at metaphase without serious chromosome alterations. Then, a dose of dimercaptopropanol, slightly bigger than that required to neutralize the arsenic, was injected. The results of a typical experiment given in Table 1 show that a significant fraction of the arrested metaphases has been able to build a normal spindle and to proceed to telophase.

TABLE 1. REVERSAL BY 1·5 mgm. OF DIMERCAPTOPROPANOL (INJECTED ONE HOUR LATER) OF THE MITOTIC ARREST AT METAPHASE PRODUCED BY 0·3 mgm. OF SODIUM ARSENITE (BONE-MARROW OF THE MOUSE)

	Arsenite alone			Arsenite + *BAL*		
Hours	Pro-phases	Meta-phases	Ana- and telophases	Pro-phases	Meta-phases	Ana- and telophases
1	16	79	5	—	—	—
2	4	94	*2*	2	74	*24*
4	2	95	3	1	89	10
5	—	—	—	1	93	*6*
24	5	63	32	11	59	30

The table also shows that the effect of dimercaptopropanol diminishes in a few hours, although there is no difference between the two series of animals after twenty-four hours. The quantity injected being sufficient to neutralize all the arsenite injected, it was suspected that *BAL* alone might modify the percentage of mitotic phases in the bone-marrow. This was in fact found: two hours after a single injection of 1·5 mgm. of dimercaptopropanol, the percentage of phases in the bone-marrow was: pro-, 3; meta-, 92; ana- and telophases, 3. Four hours after, 88 per cent metaphases were found, and these exhibited the same spindle defect as caused by arsenite. Dimercaptopropanol is in consequence also a mitotic poison, with activity similar in type to that of colchicine.

In the thymus and intestine, the same reversal of the arsenical mitotic arrest is found, as the following figures make clear:

TABLE 2. SAME EXPERIMENTS AS TABLE 1
Percentages of mitotic phases in thymus and intestine

	Pro-	Meta-	Ana- + telophase
Thymus, 4 hr. after arsenite	1	95	4
1d. and 3 hr. after *BAL*	2	60	38
Intestine, 4 hr. after arsenite	2	94	4
1d. and 3 hr. after *BAL*	5	46	49

Injection of dimercaptopropanol also prevents the 'pycnotic' effect of arsenite. In the control animal, twenty-four hours after the arsenite injection, the thymus shows few mitoses and extensive destruction by pycnosis. In the animal detoxified by *BAL*, the thymus does not present any evidence of cellular breakdown, and mitotic activity is normal. Similar pictures are to be found in the germ-centres of the spleen.

Apart from affording new evidence of the efficacy of *BAL*, these experiments are somewhat difficult to interpret. They would seem to suggest that the mitotic poisoning by arsenic is related to its action on —SH groups: arsenic might be removed from the cellular (spindle ?) —SH groups by the more reactive similar groups of *BAL*. On the other hand, it may be argued that arsenic has been removed from the organism by the greater diffusibility of its combination with dimercaptopropanol, and that no further evidence can be gathered as to the combination of arsenic and the cellular constituents at metaphase. The poisoning of metaphase by *BAL* itself certainly makes the problem more complex.

In order to test further substances with a pharmacological behaviour similar to that of arsenic and known to react with —SH groups and to poison —SH enzymes, some experiments were done with sodium selenite[26]. This was found to induce extensive pycnotic destruction of lymphocytes in thymus and spleen (5 mgm./kgm.). In the intestine, there was a slight increase in pycnotic nuclei. No metaphase arrest was observed in any tissue.

Mitotic Poisons and Ionizing Radiations

Research on mitotic poisons has demonstrated that two periods of the cellular cycle are outstandingly sensitive to chemical interference: the metaphase, or more exactly the formation of a normal polarized anisotropic spindle, and a certain period preceding prophase. The poisoning of the latter stage, corresponding probably to the increase of the thymonucleic acid content of the chromosomes, leads to nuclear destruction by 'pycnosis'. We have given several new instances of poisons acting in this way. All these produce in common an extensive destruction in the germinative regions of the lymphoid tissue and in the thymus. As A. P. Dustin pointed out many times[1,2], these effects are remarkably similar to those of ionizing radiations: the mitotic poisons of the trypaflavine type are *radiomimetic*.

This resemblance is made more suggestive by recent developments in the cytological study of radiation-effects[27], pointing to the great radiosensitivity of the period preceding prophase. When a cell is irradiated during this period it becomes incapable of normal mitosis and breaks down. The various types of nuclear destruction identified by Spear and Glücksmann[28] correspond closely to those we have met in intestine and lymphocytes. Thus the microscopical appearances of the Lieberkühn crypts after irradiation with X-rays, and after poisoning by ethylcarbamate, seem to be identical.

These facts suggest two possible explanations. The radiations may bring about the formation in the tissues of substances acting like mitotic poisons. The experiments of Schütz show the interest of cyanates in this regard, and further work along this line seems desirable. On the other hand, it may be that ionizing radiations inhibit or destroy some fundamental cellular system which is not necessary in the resting stage but becomes indispensable before prophase. Much recent work on radiations[27] indicates the possibility of the inactivation of enzymes: it will now be seen if such a hypothesis fits in with what is known about the mitotic poisons.

Recent Theories on the Mechanism of Mitotic Poisoning

The large amount of work—mostly botanical—which has followed the discovery in 1937 of the polyploidizing action of colchicine has led to the study of numerous substances with similar properties in plants, and some general theories on their mode of action. Both Gavaudan[29] and Levan and Östergren[4] have suggested a close relation between narcosis and the inhibition of spindle-formation, according to which metaphase arrest might be related to the physical properties of the poisons, in particular their lipo-solubility. Such theories may provide an explanation of the activity of various benzene and naphthalene derivatives, but do not make clear why the water-soluble alkaloid colchicine, or arsenic and mercury compounds, may alter cell division in an identical way. The recent papers of Levan[30] and Thomas[31], bringing evidence of metaphase poisoning with various metal salts and with lactic acid, show that a new approach to this problem is needed.

One hypothesis, which has not so far been put forward, though it seems suggestive, is that the various mitotic poisons act as enzyme-inhibitors, preventing either the onset of prophase or the polarization of the spindle. Of the substances studied in this article, hydroquinone, arsenic, selenite, nitrogen-mustard, carbamates and dimercaptopropanol are known to poison various enzyme systems more or less powerfully, and this property constitutes a link between them which is provided neither by their chemical nor by their physical properties.

Though hundreds of papers have been devoted to colchicine, four only have considered its action on enzymes[32], and new research in this field is urgent. It is not yet possible to assess whether one typical effect—pycnosis, for example—is induced by the poisoning of one enzyme, or if different inhibitions may lead eventually to the same cytological picture. It may be suggested that the poisons of the trypaflavine or radiomimetic group disturb nucleoprotein metabolism and the coating of the chromosomes with thymonucleic acid at prophase. This could undoubtedly be realized by various means. For example, trypaflavine, as a basic dye, may combine with nucleic acid, and carbamates may conceivably interfere with purine metabolism[5]. The poisons of the second type, acting principally on the spindle, may perhaps combine with the —SH proteins that have been histochemically demonstrated in the spindle and also in the nuclear sap[33]. In this group one may tentatively place arsenite, mercury compounds (ethyl-mercuric-chloride[34]), and the halogen derivatives of benzene and naphthalene[4]. The curious cumulative effect of ethyl-mercuric-chloride and dibenzanthracene may be mentioned in connexion with this hypothesis[35]. Other possibilities of enzyme poisoning are indicated by the colchicine effects of ethylcarbylamine[36] and of dimercaptopropanol, which both inhibit metal-enzymes.

Another problem concerns the site of action of mitotic poisons in the cell. It is widely believed that, in a way similar to radiations, they are essentially *nuclear* poisons. While this is evident for those of the trypaflavine group, the close relationship between the spindle formation and the nucleus (in particular after the disappearance of the nuclear membrane), and the pycnotic effects (in mammals) of most of the colchicine-type of poisons, suggest that these also interfere with a nuclear mechanism. It has been thought[27] that the nuclear disturbances induced by radiations may be a consequence of an alteration of the nucleolus. This does not seem to be the case with radiomimetic poisons, the nucleolus being apparently more resistant than the other cellular structures, as described above. We would suggest the possibility of changes in the nuclear sap. Here must be mentioned the interesting work of Haas[37] on nuclear poisons studied independently of cell division. In living Anodont eggs some substances were noticed to bring about intranuclear precipitations visible with the ultramicroscope. The three substances which had the most elective action on the nucleus, without modifying the cytoplasm, were the mitotic poisons caffeine[38], nicotine[39], and colchicine. Very little is known about the properties of the nuclear sap, the function of which, as an intermediary between genes and cytoplasm, is of the greatest importance. Changes in the nuclear sap may possibly give an explanation of the relations between the two types of mitotic poisoning.

Apart from the possible practical utilizations of mitotic poisons in the chemotherapy of malignant growth (ethylcarbamate[6], arsenic, colchicine[40], nitrogen-mustard[22], trypaflavine[41]), and their wide use in applied botany, it is evident that the study of these substances may increase our fundamental knowledge of the cytochemical processes of cellular division. The action of mitotic poisons on various enzyme systems needs further research, which may bring results of far-reaching importance.

This work has been supported by grants made to the Royal Cancer Hospital (Free) by the British Empire Cancer Campaign, the Anna Fuller Fund and the Jane Coffin Childs Memorial Fund, and was carried out during the author's tenure of scholarships awarded by the British Council and the Lady Tata Memorial Foundation.

PROF. PAUL LANGEVIN, For.Mem.R.S. (1872–1946)

ON May 23 and 25, scientific workers in Great Britain united to honour the memory of Paul Langevin, whose death last December was felt as a deep loss, not only to science but also to the cause of peace and social justice throughout the world.

The first meeting was a reception at the Society for Visiting Scientists, at which Prof. Joliot-Curie and the British Minister of Defence, Mr. A. V. Alexander, spoke of the contribution of Langevin to science and culture in France, and particularly to the development of the ultra-sonic detection of submarines in the First World War, which was used to such effect in the Second World War.

The second meeting, organised by the World Federation of Scientific Workers in conjunction with the Society for Visiting Scientists and the Association of Scientific Workers, was a public meeting under the chairmanship of Sir Henry Tizard, and was addressed by the Astronomer Royal, Sir Harold Spencer Jones; Sir George Thomson, who spoke of the early life and work of Langevin at the Cavendish Laboratory under his father, Sir J. J. Thomson, in 1897; Prof. J. D. Bernal, who had particularly close contact with Langevin in his later years; and by M. Biquard, of the French Commissariat of Atomic Energy and the Paris School of Physics and Chemistry, the assistant and friend of Langevin, whose moving address in memory of his master will long be remembered by those who heard it.

Paul Langevin was born in Paris in 1872 of working-class parents, and it was from his father in particular that he acquired the sense of popular republicanism that guided him throughout his life. He succeeded, through his own efforts and the obvious brilliance of his intellect, in securing an education in the École de Physique et de Chimie of the City of Paris, from which he had the great fortune of securing a scholarship to work in Cambridge in 1897. He had already absorbed the best of classical French mathematics and physics teaching, naming as his masters Brillouin and Pierre Curie, whom he afterwards succeeded as director of the School. Thus he was most fitted to profit by the really extraordinary opportunities of the Cavendish Laboratory, in the very first year that the University of Cambridge admitted foreign students, having among his companions, Rutherford, C. T. R. Wilson and Townsend. J. J. Thomson had just discovered the electron, and the significances of that discovery were being furiously pursued by these first Cavendish research workers. Langevin's own work was on the recombination and mobility of gaseous ions, and he showed his mastery of the practical and theoretical difficulties in the primitive but stimulating 'sealing wax and string' period of those days. His thesis on this subject (published in 1902), dedicated to J. J. Thomson, was shown at the meeting. His subsequent scientific work exhibited the combined influence of the practical and common-sense English school with the clarity and generalizing power of the French. Indeed, it went further, for Langevin contributed notably to the great theoretical clarifications of that period, both in the field of relativity and the quantum theory. Particularly he put forward, independently of Einstein, the celebrated law of the equivalence of mass and energy, $E = mc^2$, and he was largely responsible for the introduction of these modern views into French science.

The main trend of Langevin's scientific work lay, however, in the direction of the interaction of systems. He was able, in 1907, to explain the phenomena of paramagnetism observed by Curie as due to the mutual interaction of elementary magnets under the influence of thermal agitation, and thus, by the celebrated Langevin equation, to lay the foundations of the study of what are now known as co-operative phenomena, which are seen to-day to be the key to some of the most important features of the solid and liquid states of matter.

In the First World War Langevin turned his talents, as theorist and experimenter, to the development of ultra-sonic vibration by the use of piezo-electric oscillators. The immediate application of this was to the detection of submarines by the reflexion of these waves. In this new field he overcame all experimental difficulties, and already in 1917 was able to demonstrate the detection of submarines under water at a distance of a kilometre. This method was not in operational use in the First World War, but it was the basis of the 'Asdic' which was of such offensive and defensive value in the Second World War. Indirectly, it had even more widespread effects. Piezo-electric oscillation came to be used in many other applications in the electronic field, and echo detection, using electronic instead of sound apparatus, was, of course, the basis of radar and its modern application in war and peace.

The main value of Langevin's scientific contribution, however, was indirect and explicitly appreciated only in France. The many years that he taught at the École made that institution the centre of formation for a brilliant school of French physicists, of whom Joliot-Curie is the most illustrious. Langevin was always interested in scientific education, and in the latter years of his life was given the direction of the reform of this education in France, a reform long overdue, but one for which his particular combination of enthusiasm and breadth of outlook most fitted him.

Paul Langevin, however, will be remembered in France and throughout the world even more as a man and as a citizen than as a scientific investigator. From his early scientific days he realized the obligations of the man of science to fight for justice, in supporting the protests against the condemnation of Dreyfus. "Those were happy times," he said later, "when the fate of a single man was so valuable that it could excite the whole of mankind." The fight he began then he carried on for the rest of his life. He was active in the Ligue des Droits de l'Homme and became its chairman after the brutal murder of Victor Basch and his wife by French Fascists. The advent of the Nazis to power in 1933 put France in the forefront of the fight against Fascism, and Paul Langevin took a leading part in organising it. He was one of the founders of the Comité de Vigilance des Intellectuels Anti-Fascistes, and after the Fascist riots in Paris in 1934 he also took a great part in the formation of the Front Populaire.

It was at this point that his activity in the international sphere also began. He, first among eminent men of science of the world, called for a rallying of all forces against the threat to liberty and progress that Nazism represented. He was able, by his action, to show how possible, and indeed how necessary, it was, to combine, when the times demanded it, the role of citizen with that of scientist. He was instrumental in founding in Britain an analogous body "For Intellectual Liberty" which, together with the Comité de Vigilance, carried out an unceasing activity of protest against the successive surrenders to Fascism, beginning with the Anglo-German naval treaty, continuing through the farce of non-intervention to the capitulation at Munich.

As such, Langevin was inevitably a marked man after the German occupation. He had courageously refused to leave France, though he might easily have done so, and he had the honour to be arrested by the Gestapo on the basis of the *Führerprincip* as the most representative of all the intellectuals who had fought against Hitler. The main charges against him were his chairmanship of the Ligue des Droits de l'Homme, and because he had tried to prevent Germany from ridding itself of the Jews. He was released from prison partly as a result of the protests of French students and professors, but kept under confinement at Troyes, from which he was rescued by the Resistance after some years, and smuggled into Switzerland. He had to suffer more, however, from the fate of his family. His son-in-law Solomon was shot for his part in the Resistance movement, and his daughter Hélène was sent to the notorious death-camp at Auschwitz, from which, however, she managed to escape. Broken in health but not in spirit, Langevin returned to Paris after the liberation, where he took the place which had been occupied by his son-in-law in the Communist Party, and at a great meeting in the Sorbonne was accorded the homage not only of the French intellectuals, but also of the people of Paris and the fighters of the Resistance movement.

The last task of his life was the reform of education, in which he embodied his ideals of social reform. "The final objective would be to find for the individual in human society his rightful place in every respect. Society will then appear to every one of its members as a living entity in which each of us is entrusted for a while with a treasure of civilization acquired by our ancestors at the price of innumerable hardships and pains, which it is our duty to pass on after enriching it according to the extent of our ability. . . . Let us hope that every child, on leaving our schools of to-morrow, will be convinced that the two moral sins of conformity and selfishness respectively oppose the double imperative duty of personal achievement and social solidarity."

The meetings which have been held in his memory in Paris and now in London serve to emphasize the growing unity of science and society throughout the world, and in particular the close ties that have been forged by the experience of recent years between the scientific workers of Britain and France. It is in furthering this unity that we can best honour the memory of Paul Langevin. J. D. BERNAL

CENTENARY OF THE INSTITUTION OF MECHANICAL ENGINEERS

By R. H. PARSONS

THE Institution of Mechanical Engineers, which has celebrated its centenary this week, can look back upon a hundred years of invaluable service both to the profession and to the community. Its existence has been contemporaneous with almost incredible developments in engineering, metallurgy and general science brought about largely by the work of its members. When it came into being, engineers had no such materials as even mild steel or aluminium, no mineral oil, no artificial abrasives, no electrical generators and no internal combustion engines of any kind. Their machine tools were comparatively few and simple, screw-threads had not yet been standardized, precision measurements were impossible, and scientific knowledge applicable to engineering problems scarcely existed. The steam engine, much as it had been left by Watt, was, however, available for industrial purposes, locomotives were running on the railways, and steam had been applied to marine propulsion.

The Institution was founded in Birmingham on January 27, 1847, by a meeting of some of the leading mechanical engineers of the day, and George Stephenson, who had taken an active part in the proceedings, was elected by acclamation as its first president. The object of the Institution, in the words of its founders, was "to enable Engineers . . . to meet and correspond, and by a mutual interchange of ideas . . . to increase their knowledge and give an impulse to inventions likely to be useful to the community at large". Birmingham was decided on as its headquarters, as being the most convenient centre for engineers engaged either directly or indirectly with the development of railways, which then constituted one of the most important fields for engineering activity.

After the death of George Stephenson on August 12, 1848, his son Robert, who acquired the same unrivalled eminence as a railway engineer, was elected president of the young Institution. Other well-known names, such as Fairbairn, Whitworth, Penn, Armstrong, Napier and Siemens among the early presidents, bear witness to the prestige the Institution has enjoyed since its inception. In 1856 it took a step which greatly extended its influence and usefulness. This was the inauguration of its annual summer meetings, lasting two days or more, and held in some selected industrial centre or sometimes abroad. Such meetings have remained among the most appreciated functions of the Institution. An outstanding event in the history of the Institution took place in 1877, when the headquarters were transferred from Birmingham to London. At this time the membership was somewhat more than a thousand. In 1895 it began the construction of its present worthy home at Storey's Gate, St. James's Park. This was formally opened in 1899, and considerably extended in 1913. By then the Institution comprised more than six thousand members, and the rapidity of its subsequent growth is shown by the fact that at the end of last year it had almost 25,000 members of all classes, to which must now be added the considerable number of members recently admitted by the absorption of the Institution of Automobile Engineers.

The increase of membership from all parts of Britain led, in 1920, to a measure of decentralization, whereby local branches, managed by their own committees, which are represented by their chairmen on the Council of the Institution, were established in large centres of population. There are now nine such branches, covering between them the whole of Great Britain, each providing opportunities for its own discussions and other activities. Similar branches also exist in China, the West Indies and the Argentine, while advisory committees serve the interests of the Institution in seven other countries overseas. Another outcome of the increased membership has been the formation of specialized groups within the Institution. These are composed of engineers having a common expert interest in particular subjects, as, for example, steam, hydraulics, internal combustion engines, manufacturing, education, and so on. These groups are assisted by the Council in arranging their own meetings and discussions.

Thanks mainly to benefactions by its members, the Council of the Institution now has at its disposal valuable funds for the provision of monetary awards or medals for special lectures or particularly meritorious papers. One of its highest awards is the Watt International Gold Medal, which is bestowed biennially on some distinguished engineer, without regard to nationality, for exceptional services to science or industry. The decision is made by the Council in the light of the opinions of the leading foreign institutions, and the recipients so far have included two Englishmen, two Americans, one Australian and one Swiss. Some of the other prizes are awarded in respect of specified subjects, but in the case of others the Council has a wide discretion. Any person, for example, whether a member of the Institution or not, may be invited to deliver the well-known annual Thomas Hawksley Lecture. Lectures in this series have been delivered by such authorities as the late Sir Alfred Eddington, the late Lord Rutherford and others of similar eminence. In 1945 the Institution received the magnificent bequest of £130,000 under the will of the late Mr. James Clayton, with the condition that at least one quarter of the annual income should be used in providing a "James Clayton Prize" for the best contribution by any member in that year to modern engineering science. The first award under this bequest was made to Air-Commodore Frank Whittle for his development of jet-propelled aeroplanes.

It may fairly be claimed that no other technical organisation has so fine a record as the Institution of Mechanical Engineers in the matter of corporate research work, carried out for the benefit of the profession in general. So long ago as 1875, the Council adopted a policy of giving financial support to engineering research, and in 1879 it appointed a standing research committee to decide on and supervise such investigations as might be desirable from time to time. Very large sums have been spent by the Institution on such work, which has been carried on uninterruptedly ever since. The results of the various investigations form the basis of discussions by the members, and are then published for the benefit of all persons interested. The range of subjects is too great even for a summary here, but mention ought at least to be made of the classical experiments of Beauchamp Tower in 1882, on which the whole of the modern theory of lubrication is based, and of the work of the Alloys Research Committee which was started under the direction of Sir William Roberts-Austen in 1889 and has since been productive of immense advances in metallurgical knowledge. The Institution also took up the question of standardization at an early date, and played an active part in the establishment of the Engineering Standards Committee in 1901, to which body matters concerned with standardization have since been referred.

The Institution Library now comprises more than 35,000 volumes, arranged accessibly for consultation, and also available for loan to members who wish to borrow them. There are, in addition, some two hundred British and foreign current technical periodicals in the Reading Room. Visits to the Library or Reading Room now exceed 10,000 annually. The assistance and advice of the staff are, moreover, at the disposal of members seeking information either personally or by correspondence, and the necessary searches are carried out for them.

To maintain the high standard of qualifications required for admission to the Institution, after 1912 the election of the younger candidates was made conditional on their passing an examination in general and technical knowledge in addition to the conditions previously demanded, except in cases where the possession of an approved degree or diploma rendered any further examination unnecessary. The interest and the influence of the Institution in engineering education led to its being consulted by the Board of Trade in 1921 when the advisability of revising the old "Science and Art" examinations was under consideration. The outcome of these discussions, largely due to the late Dr. H. S. Hele-Shaw, was the establishment of the present system of National Certificates in Mechanical Engineering. These are granted on the result of examinations in which assessors appointed by the Institution can set up to 40 per cent of the questions, and can render compulsory any particular questions up to the same percentage of the total. The Institution thus exercises a very strong influence on the type of education given. The certificates awarded bear the signatures of the president of the Institution, of an official of the Board of Trade, and of the principal of the educational establishment concerned. The number of students who sat for these examinations in 1946 was nearly 12,000. The Institution shows its confidence in the scheme by exempting the holder of a Higher National Certificate from further examination in the subjects covered.

In 1929 the Institution of Mechanical Engineers was granted a Royal Charter in recognition of its position as the accepted embodiment of the profession. As such it enjoys the patronage of H.M. King George VI, and, apart from the services of its individual members, it has, in its corporate capacity, rendered invaluable assistance to the Government during and since the War.

OBITUARIES

Sir Granville Orde Browne, K.C.M.G.

SIR GRANVILLE ST. JOHN ORDE BROWNE, who died on May 12, was a pioneer in work for the improvement of labour conditions in the British Colonies, particularly in Africa. Born in 1883, he first went to Africa as an artillery officer in the Zulu War of 1906. In 1909 he joined the administrative service in Kenya; his observations made among some of the minor tribes (Chuka, Embu, Mwimbe, Emberre) were published in 1925 in his book "The Vanishing Tribes of Kenya". Recalled to the colours in 1914, he served throughout the East African campaign, and his experience with native carriers aroused the interest in native labour which dominated the rest of his life.

Orde Browne was posted to Tanganyika in 1920, and in 1926 became labour commissioner, the first holder in Africa of such a post. His "Report on Labour in the Tanganyika Territory", published in that year, was a landmark at a time when many employers still depended on the penal sanction for breach of contract to keep their labourers at work. Most of the points he made have become commonplaces to-day—the need for acclimatization of the labourer to his new surroundings, particularly where these involve a radical change of diet, and for an appreciation of the reasons for 'desertion' and for dealing with it by sympathetic discussion of difficulties rather than by penalties. He advocated measures to mitigate the hardships of the long journey on foot to the place of labour, which have still scarcely been taken on an adequate scale.

When in 1931 Tanganyika decided to abolish the Labour Department and add its duties to the responsibilities of administrative officers, Orde Browne resigned from the Colonial Service, but his interest in Colonial labour questions continued. His book, "The African Labourer", published in 1933, discussed the problems of labour welfare and protection from every angle and compared the practice of the different colonial Powers. In 1934 he became a substitute member of the International Labour Organisation's Committee of Experts on Native Labour, and took part in the drafting of the conventions on recruiting and contracts which have been adopted by that body. He supplied the original draft for the chapter on labour in Lord Hailey's "African Survey".

After being commissioned in 1937 to make an inquiry into conditions on the copper belt of Northern Rhodesia, where there had been serious riots, he was appointed labour adviser to the Secretary of State in 1938, and in turn visited and reported on the West Indies, West Africa, Ceylon, Mauritius and Malaya, and East Africa. The creation of a specialist Labour Department in every Colony, which he persistently advocated, is now official policy. He was created C.M.G. in 1942 and K.C.M.G. in 1947. LUCY MAIR

Prof. Walter Ramsden

PROF. WALTER RAMSDEN, emeritus professor of biochemistry in the University of Liverpool, died on March 26 at the age of seventy-eight. He went to Liverpool from Oxford in 1914, following Benjamin Moore in the chair of biochemistry. The subject was still in its infancy, attracting comparatively few graduates and scarcely any science students. Ramsden's teaching was mainly concerned with medical undergraduates, and for them he introduced for the first time a course of lectures in the subject, together with practical classes. These admirably covered general principles, but did not overburden the student with detail. The result was that when the medical student had passed the second M.B. examination he entered the hospital wards with an interest in the biochemical problems of disease—an approach which at that time was comparatively new and exciting.

Ramsden was a shy, retiring man, and his formal lectures could scarcely be heard beyond the front two rows. Moreover, his tiny handwriting, whether on the blackboard or on paper, was difficult to read. Students often react to this situation by merciless ragging; but his gentleness and old-world courtesy captured them, especially as they appreciated that they were listening to a distinguished scholar and pioneer in his subject. In individual contacts, as when answering questions after the formal lecture, or in the practical class, he was at his best. His nicknames ("Rammer" at Oxford and "Rammie" at Liverpool) revealed the kindly affection with which his students regarded him.

His influence upon the Liverpool medical school and upon the University was that of a gentleman, a scholar and a man of science—quiet, unobtrusive, but far-reaching. He planted seeds, almost by stealth, and left them to grow.

Ramsden's main interests lay in the behaviour of proteins and of surface membranes, yet he always found time for young clinicians and others who were feeling their way towards the answers to varied problems, practical or academic. He entered unselfishly and wholeheartedly into their problems, and gave them the guidance and help of a master. He published comparatively little, though he wrote much that never came to publication, for he was almost exasperatingly modest and meticulous. He was rarely satisfied with what he wrote, and as he was always learning from his researches, he never reached that finality which he felt justified publication.

When he retired from the chair at Liverpool in 1930, and returned to Fellows' Room of Pembroke College, Oxford, his friends hoped that more of the material which he had accumulated would be made available for wider study and appreciation. He continued to follow his bent, bred silkworms and studied silkworm protein; but the papers which might have come never came.

He was a personality, and while he was at Liverpool the University and the medical school felt him to be a rare and distinguished possession. A shy and most courteous host, he had a mellow humour and a fund of good stories. ROBERT COOPE

Dr. Seymour Hadwen

ISAAC SEYMOUR ANDRÉ HADWEN, who died recently, was born at Lees, Lancashire, in 1877. He obtained the doctorate in veterinary science at McGill University in 1902, and it is of interest to note that he was a member of a small band that studied the subject at McGill. The Veterinary School there owed its development to a considerable extent to Sir William Osler at the time when he was at the McGill Medical School. The School had a very short life, however, and closed soon after Hadwen graduated. Thereafter veterinary education in Canada was maintained on a less ambitious plane for a good many years, until the course at the Ontario Veterinary College was expanded and its graduates were admitted to the doctorate of the University of Toronto.

Hadwen joined the Health of Animals Branch of the Dominion Department of Agriculture in 1904 and worked for a good many years at Ottawa, and also in British Columbia, on a variety of animal health problems important in Canada; for the latter part of that period he held the post of chief pathologist in that Department. In 1920 he left the Department as he felt that the research branch was not developing in the way he considered it should, and joined the United States Bureau of Biological Survey as chief veterinarian and parasitologist, Reindeer Investigation, in Alaska. From 1923 until 1929 he held the post of research professor of animal diseases in the University of Saskatchewan, and in 1929 became director of the Department of Veterinary Science, Ontario Research Foundation, from which he retired in 1942.

Hadwen was an outstanding man with a great deal of the pioneer in his character. He could study minutiæ and did so constantly; but it was the wide range of biology that attracted him, the play of the environmental factors, and the struggle of animal life to maintain existence. Most of his personal work centred around parasitology, but many other subjects claimed his attention.

Early, in his professional career, Hadwen was associated with the late Prof. G. H. F. Nuttall in studies on the chemotherapy of piroplasmosis in dogs and cattle, in the course of which the fundamentally important discovery was made that trypan blue is specifically curative—a landmark in chemotherapy. He contributed largely to the literature of a problem still unsolved, namely, the causation of bovine chronic hæmaturia, a disease that is endemic in different countries. Ticks and the diseases with which they are associated interested him tremendously, and he had ample opportunity to study the problems concerned. His publications on 'tick paralysis' as it occurs in Canada are still important; the disease has since been studied in Southern Europe, Africa and Australia, but its real nature has still to be demonstrated. He contributed work on the systematic classification of ticks and on their bionomics. Warble flies interested him greatly, and he made important observations on *Hypoderma bovis* and studied other members of the group. Helminth parasites, too, he understood well and studied continuously.

In his later work at the Ontario Research Foundation the subjects were those of importance to the Ontario Province. Much of it was done with Dr. R. Gwatkin and various colleagues, on bovine contagious abortion, mastitis and other problems of intensive husbandry very different from those to which he devoted most of his life.

Hadwen contributed important reports on reindeer; on the management of the herds, fertility in reindeer, their diseases and the manner in which reindeer meat in Alaska could be marketed on a large scale. He had travelled in Labrador and Lapland, studying the problems that had aroused his interests in Alaska. His work and publications indicated measures necessary for the maintenance of health of the herds and the need to change methods that had led, even in such a land of wide open spaces, to seasonal over-crowding with consequent parasitic infestation and ill-health. Wild animals had claimed his attention, and his writings include observations on snowshoe hares and on seals. In addition, he made expeditions to Labrador, and with the East Arctic Patrol to Ellesmere Island.

Hadwen was a member of several learned societies and had been elected an honorary member of the Section of Comparative Medicine, Royal Society of Medicine.

W. A. Pool

Mr. C. H. Creasey, O.B.E.

The death is announced of Clarence Hamilton Creasey at Llangerniew on May 22. Educated at the Royal College of Science, he became principal of Wellingborough Technical Institute, and inspector of technical schools under the Board of Education. He was the author of books on continuation and technical education and was a popular lecturer and broadcaster. He collaborated with Prof. A. S. Eve in writing the "Life and Work of John Tyndall", published in 1945; and with H. G. Wells in "Work, Health and Happiness of Mankind". His book, "Discoveries and Inventions of the Nineteenth Century", published under the pen-name 'Edward Cressy' in 1914, was widely appreciated. Under the same pseudonym, he also wrote "An Outline of Industrial History" (1915), "A Hundred Years of Mechanical Engineering" (1927), "Stories of Engineering Adventure" (1928), "Civil Engineering To-day" (1938). He took an active part in the organisation of education for gas engineers in association with the Institution of Gas Engineers.

NEWS and VIEWS

Trinity College, Cambridge

At the celebration, on June 3, of the four hundredth anniversary of the foundation of Trinity College, Cambridge, the guests of honour were the King and Queen, and the Duke and Duchess of Gloucester. As the royal guests drove across Great Court between crowds of cheering undergraduates, a fanfare of trumpets sounded triumphantly in welcome from above the Great Gate. After a short service in the College chapel, representatives of the town and the university waited upon their Majesties, and the morning's proceedings culminated in lunch in Hall. During the afternoon, a garden-party was held under ideal conditions, and representatives of many different types of College activity were presented to the King. The celebrations ended at five o'clock, except for a very fine firework display late in the evening, which included as a set piece a realistic portrait of the College founder, King Henry VIII.

An outstanding feature of the day was the speech at the luncheon by the King, proposing the health of the College. He spoke of the pleasure felt by the Duke of Gloucester and himself in returning to the College which they entered as undergraduates just after the First World War, and praised the outstanding contributions of members of Trinity in the State, in the humanities and in science. In particular, he referred to the introduction of the principles of inductive logic by Bacon, and their first flowering in the great achievements of Newton. In replying on behalf of the College, the Master also spoke of the extension of natural science in the hands of Maxwell, J. J. Thomson and Rutherford, and mentioned with regret the recent death of another famous Trinity man of science, Sir Frederick Gowland Hopkins. The Master discussed, too, the value of residential colleges in fostering breadth of vision, and encouraging friendship and the free exchange of ideas between those working in the sciences and in the arts. All the friends of Trinity will join in hoping that the contributions of the College to the solution of the problems of to-day and of the future may equal and even exceed the achievements of its illustrious past.

Prof. J. H. Quastel, F.R.S.

The Montreal General Hospital has established an Institute of Special Research and Cell Metabolism under the direction of Dr. I. M. Rabinowitch, and has appointed Dr. J. H. Quastel as director of the Enzyme Research Division and associate director of the Institute, while McGill University has simultaneously announced his appointment to a professorship in the Department of Biochemistry, the chairman of which is Prof. D. L. Thomson. Prof. J. H. Quastel graduated at the Royal College of Science, London, and went to

Cambridge in 1921 as a research student under the late Sir Frederick Gowland Hopkins. These were the pioneering days of enzymology, which saw its development into an exact science, and it was to this field that Prof. Quastel made some of his most important contributions. His exhaustive studies of the resting metabolism of bacteria, which form the basis of present-day microbiological techniques, led to the characterization of new enzyme systems, while his discovery of the specific competitive inhibitors of enzyme action has had the widest application in this field. Prof. Quastel's fundamental contribution at this time was his work on the reversibility of dehydrogenase action. Working with succinic dehydrogenase, he showed that the change in free energy determined from the observed equilibrium point agreed closely with the value calculated from thermal data.

In 1929 Prof. Quastel was appointed director of research to the Cardiff City Mental Hospital, where he investigated the biochemical aspects of mental disease. Fruitful results arising from the integration of clinical and research aspects of these problems has encouraged the development of similar units elsewhere. Following the outbreak of war, Prof. Quastel accepted in 1941 the invitation of the Agricultural Research Council to organise a Unit of Soil Biochemistry at Rothamsted. In this field his work showed the same originality of outlook that was apparent in his earlier work. By repeated percolations of a small quantity of soil by an aqueous solution in a closed circuit and periodic addition of reagents or removal of samples for analysis, detailed qualitative data on soil metabolism, in particular nitrogen metabolism, were obtained. Prof. Quastel was awarded the Meldola Medal in 1927, and was elected a fellow of the Royal Society in 1940. One can with confidence anticipate the development, under his guidance, of a vigorous school of cellular metabolism at McGill University.

Institute of Fuel : New Building

The Institute of Fuel was founded in 1927, soon after the general strike in Britain—a national disaster which started much thought about fuel problems. In several directions action was taken to establish new technical organisations which eventually, by processes of mutual attraction or absorption, led to the foundation of this Institute of Fuel. After ten years or so of useful work, the Institute gathered together about 1,000 members. Then came the War to provide new tasks and opportunities for service which the staff and members were able and ready to seize. As a result, its roll of members has since increased threefold. Regional sections have been formed, schemes of education have been launched, including examinations to qualify for membership, and in 1946 a petition for incorporation by Royal Charter was granted. This year, in order to carry on its work more effectively, the Institute has acquired permanent headquarters at 18 Devonshire Street, London, W.1. It has issued an appeal to all who are interested to contribute sums in support. Already about £8,000 has been received. Cheques should be addressed to the Secretary, Institute of Fuel, 18 Devonshire Street, London, W.1.

Civil Aircraft Research

It has been announced that the terms of reference of the Civil Aircraft Research Committee of the Aeronautical Research Council are : "To consider the basic research problems arising from the evolution and operation of civil aircraft, having regard, *inter alia*, to the probable requirements of the operators ; to recommend periodically to the Council programmes of research ; and to report to the Aeronautical Research Council". The members are Prof. A. A. Hall (chairman), Prof. A. R. Collar, Dr. T. E. Easterfield, Prof. S. Goldstein, Major F. M. Green, Sir Melville Jones, Prof. R. L. Lickley, Dr. H. R. Ricardo, Mr. P. A. Sheppard, Prof. G. Temple, and representatives of the Ministry of Supply, the Ministry of Civil Aviation, the National Physical Laboratory, and the three airways corporations.

Zoological Society of Bengal

The Government of India has recently decided to transfer the office of the Zoological Survey of India from Calcutta to Delhi. As a result, the zoologists of Bengal will be deprived of the use of the only zoological library in that part of the country. In order to meet this difficulty, the Zoological Society of Bengal is issuing an appeal for assistance in the hope that zoologists will present them with reprints of their papers and put the Society on their mailing lists. The Zoological Society of Bengal was only founded last year, but the annual report for 1946 shows that already 294 members have been enrolled and various meetings held. Among the speakers has been Prof. H. Munro Fox, one of the British delegates to the Indian Science Congress Association. The Society proposes to issue monographs of typical Indian animals and also a bulletin dealing with simple zoological laboratory technique. It also hopes to publish a journal devoted to zoological research in India. The president is Prof. H. K. J. Mookerjee, and secretary, Dr. S. P. Ray Chaudhuri. The Society's address is 35 Ballygunge Circular Road, Calcutta.

A Science Journal for South Africa

At a meeting of the South African Association for the Advancement of Science, held in Johannesburg on May 16, it was resolved that the Association should commence publication at the earliest possible date of a monthly periodical covering the whole field of science. The venture will be paid for by the Association and will not be in any way a profit-making organisation ; it is intended that the journal should be distributed free to all members of the Association, and that it may later be made available for sale to the public. It is hoped to present leading articles, reviews of books, and articles of a general character, and to devote three or four pages to "Letters to the Editor", a section which it is hoped will become a forum for scientific discussion. It is intended that articles, etc., should be of such a nature as to appeal to scientific workers in fields other than those of their own speciality, and it is believed there will be sufficient popular material to appeal to the more general reader of scientific interests. The journal will be produced by the Association, the honorary editor being Dr. H. B. S. Cooke, of the University of the Witwatersrand.

American Institute of Physics

The January issue of the *Review of Scientific Instruments* contains an important announcement concerning the reorganisation of the American Institute of Physics. The five societies, the American Physical Society, the Optical Society of America, the Acoustical Society of America, the Society of Rheology and the American Association of Physics

Teachers, which are members of the Institute, have unanimously ratified a change in the constitution under which members of the societies automatically become individual members, without additional subscriptions, of the Institute, thus creating a large unified professional body of physicists. The amended constitution and the new rules are printed in full. No change is made in the organisation, functions or activities of the member societies; but the way is opened for all persons interested in physics to play, individually, a greater part in the affairs and interests of physics, where these are of common concern and can prosper best by the combined active support of all. Provision is made under the new constitution for others, not members of the participating societies, to become associate members of the Institute.

It is intended, when sufficient finance is available, to establish an official monthly journal of the Institute, to be sent without additional charge to all members of the Institute. This journal will contain news about physicists, their meetings, work and other activities, and about similar features in related fields; information about the action of government and other non-physical agencies affecting physics; articles and letters expressing views of physicists on problems of general importance; references to current literature in physics; book reviews, etc. When this journal, for which the title *Physics* has been suggested, appears, the *Review of Scientific Instruments* will revert to a journal devoted exclusively to the science of instruments. It is hoped that associate members, who will be recruited from the very large number of school teachers, students and others who have graduated in physics and thus have an interest in the subject, will be encouraged through the medium of the new journal to become members of one or more of the participating societies.

Fresh Water Biology in Italy

FOUNDED in 1939 by private endowment, the Istituto Italiano di Idrobiologia de Marchi, at Pallanza (Province Novara), is scarcely known abroad. It is situated on the north shore of Lake Maggiore in one of the most suitable and beautiful sites for carrying out research and enjoying the surroundings. Its excellent equipment for field and laboratory research, its spacious accommodation and its sub-station—in a beautiful villa on Lake Como—provide full facilities for any kind of limnological investigation on the great lakes at the foot of the Alps; and a number of smaller lakes all the way up the slopes of the Alps are within easy reach. The main activities of the staff are freshwater ecology, systematics and genetics, a series of papers having already appeared as the Institute's *Memorie*. Free lodging and free laboratory facilities are offered to foreign guests (up to five at one time). Other facilities may be arranged for by agreement with the director, Dr. E. Baldi. Pallanza is easily reached from either of the two international railways, the Simplon and the St. Gotthard.

Radiolocation Convention Papers

As already mentioned in *Nature* (February 1, p. 174), the *Proceedings* of the Radiolocation Convention held at the Institution of Electrical Engineers in 1946 are being published as a series of special numbers of Part 3 of the *Journal of the Institution*. Five such numbers have now been issued, and reference has already been made to the first two. No. 3 contains two papers dealing with some aspects of the propagation of radio waves overland in the wave-length range 10 cm.–10 m.; and nine papers describing the development for radar purposes of special aerial systems for use in the metre band of wave-lengths between 1·5 and 15 metres. The corresponding developments in aerial systems for centimetre wave-lengths are dealt with in a series of six papers forming part of the fourth number (Vol. 93, Part III A, No. 4) of this special publication.

Since it is in the centimetre range of wave-lengths that the wave guide replaces wire circuits and cables for connexions between different parts of the radio-frequency equipment and between the equipment and the aerial system, it is natural to find the twelve papers on wave guides also in this fourth special number. These papers deal with some of the problems involved in design and in the application of wave-guide technique to very short wave radio equipment. The fifth number (Vol. 93, Part III A, No. 5) contains five papers on cathode-ray tubes and twelve on valves. In the first place, these describe some of the advances made in the use of cathode-ray tubes, with special screens in many cases, for radar display purposes. The second series of papers provides a comprehensive record of the special valve development conducted in Great Britain during the War, ranging from triodes for very short waves, the conception and development of that important device, the resonant cavity magnetron, to the high-power pulsed magnetron and the velocity-modulation reflexion oscillator. Since a crystal detector, now termed a crystal valve, is an essential part of all centimetre wave radio receivers, a paper on this subject is included in this particular number of the publication.

National Museum of Wales

THE report for 1946 of the National Museum of Wales again exhibits that activity of service (external as well as internal) which is conformable with the purport of a great institution. In this report the acquisition of St. Fagans Castle and grounds for use as a Welsh folk museum is fully discussed; plans for its future organisation are outlined, and it is stated that part of the new folk museum and grounds will be opened to the public during the present year. An interesting development, and one which would seem to offer scope for the future, was the circulation in 1946 of a travelling exhibition of the Llyn Cerrig and Valley aerodrome finds—finds which had "excited so much interest throughout the Principality and especially in the island" (Anglesey). The exhibits were first set up at Holyhead, where an official lecture was given, then at Llangefni, and finally at Bangor. At each of the first two places it remained four weeks, and at Bangor for a longer period. It is of further interest that this movement was made in response to a request from the Anglesey Education Committee and the Committee of the Museum of Welsh Antiquities at the University College of North Wales, Bangor.

Departmental reports are primarily concerned with routine work, and the work of reorganisation which necessarily follows the return of collections from war-time storage. During the year some of the reference collections were again available for use. Those who believe in the practical educational value of museums under adequate schemes of organisation will be interested in the development regarding the proposed schools service mentioned on p. 20 of the report. This states that the Parliamentary Secretary to the Ministry of Education, Mr. D. R. Hardman, has visited the Museum as a result of a memorandum outlining a scheme which was presented to the Ministry in 1944, and "It is understood that the Ministry is now in consultation with Local Education Authorities in Wales on the matter". Appendixes at the end of the report include lists of acquisitions, publications by members of the staff during the year, and the usual list of the Museum's handbooks and guides.

Waxwing Immigration

THE severe winter of 1946–47 was marked in England by an abnormal immigration of waxwings (*Bombycilla garrulus*) and great grey shrikes (*Lanius excubitor*), particularly the former. Appearing near Edinburgh in November, flocks of waxwings quickly spread over the eastern counties of England in the latter months of 1946, and in late December appeared in Lakeland, where some flocks of more than twenty birds were noticed. In December and January several birds appeared in Lancashire and Cheshire, near Lancaster, Liverpool, Altrincham and Chester, and as usual in these immigrations the birds were attracted to berry-bearing shrubs and were exceedingly tame. There was a previous immigration of these noticeably brilliant birds into the eastern counties early in 1943; but they do not usually penetrate in such large numbers as occurred during the recent immigration into the western half of Britain. Nesting in North Europe, their irregular visitations to Britain were first recorded near York in 1681 (*Phil. Trans. Roy. Soc.*). Odd birds occur almost every winter in Scotland, but Irish records are much fewer than those in England.

Proceedings of the Tenth International Congress of Chemistry

THE full *Proceedings of the Tenth International Congress of Chemistry*, which was held in Rome in May 1938 under the presidency of the late Prof. Nicola Parravano, were published in five volumes in Italy during the years 1938–39. Owing to the outbreak of war, many libraries in Great Britain and elsewhere will have failed to receive complete sets of this important publication, and they will be glad now to learn that copies of the five volumes are still available. Full particulars may be obtained from Prof. Guido Bargellini, Istituto Chimico, Città Universitaria, Rome, to whom also orders for any of, or all, the volumes should be addressed.

Lord Kelvin and the British Metrical System

ON June 2, 1897, in his well-known address to the Victoria Institute on "The Age of the Earth", Lord Kelvin said: "I must first ask you to excuse my giving you all my depths, heights, and distances, in terms of the kilometre, being about six-tenths of that very inconvenient measure the English statute mile, which with all the other monstrosities of our British metrical system, will, let us hope, not long survive the legislation of our present Parliamentary session destined to honour the sixty years' Jubilee of Queen Victoria's reign by legalising the French metrical system for the United Kingdom". The Weights and Measures (Metric System) Act was passed, and it is no longer a punishable offence for a tradesman to have in his possession a weight or measure of the decimal system. But with all the "monstrosities of our British metrical system" still surviving, it is interesting to recall the fiftieth anniversary of Lord Kelvin's unfulfilled hope.

Announcements

DR. T. F. WEST, author of papers on D.D.T., has been appointed an assistant director of the Ontario Research Foundation, and will leave London to take up his duties in Canada in July.

DR. D. W. DAVISON, of the physics staff of the Brown–Firth Research Laboratories (Thos. Firth and John Brown, Ltd., Sheffield), has been appointed a senior research officer, Council for Scientific and Industrial Research, Australia, in the Research School of Metallurgy at the University of Melbourne, where he will join a team working on the physics and crystallography of ferrous and non-ferrous metals, under Prof. J. Neill Greenwood.

SIR ROBERT ROBINSON, president of the Royal Society, will open a new research laboratory in the Department of Chemistry, University of Glasgow, on June 25; the laboratory is to bear the name of G. G. Henderson.

As a result of a meeting of mycologists and plant pathologists at the Indian Agricultural Research Institute, New Delhi, on February 28, the Indian Phytopathological Society was initiated. All persons interested in the study of fungi, bacteria and viruses are invited to join the Society. Further information can be obtained from the Secretary-Treasurer, Indian Phytopathological Society, Agricultural Research Institute P.O., New Delhi.

THE report of the Conference on "Research and the Smaller Firm" arranged by the Manchester Joint Research Council last October (see *Nature*, 158, 638; 1946), which has now been published (from the Manchester Chamber of Commerce. 2*s*. 6*d*.), includes an account of the proceedings of the Conference with a full report of the discussions at both sessions. The papers by Mr. C. E. Renold, Dr. C. J. T. Cronshaw and Dr. F. C. Toy are appended, with written contributions from Mr. H. Downs and Mr. J. Williams and a note on the Manchester Federation of Scientific Societies.

DETAILS of the Industrial Film Service of the Blackheath Film Unit (9 North Street, Leatherhead), which has already been responsible for such outstanding films as "Training of the Disabled", for the Ministry of Labour and National Service, and "Sugar Beet", for the Ministry of Agriculture, are outlined in a sixteen-page brochure issued by the Unit. The Unit is equipped and staffed to undertake the production of any type of industrial or instructional film, and can also provide a complete technical service to the film units of its clients.

THE Göteborgs Högskola has awarded the Heyman Prize (value about £700) to Börje Kullenberg, in recognition of his distinguished work in constructing the piston core-sampler, which has provided the means for a new departure in submarine geology. The piston core-sampler has proved capable of securing practically undisturbed sediment profiles up to 20 metres in length. It was used with great success on the *Skagerak* Expedition to the western Mediterranean during April–May 1946, when long cores were obtained down to a maximum depth of 3,600 m. It will be used from the coming Swedish circumnavigating deep-sea expedition with the *Albatross*. The Heyman Prize is given at intervals of three years, for literature and for science alternately. In 1941 the first science award was divided between the two eminent Swedish geologists, Helge Backlund and Lennart von Post.

Inhibition and the Polarity of the Retinal Elements

THE retinal elements in the cat's eye[1], as isolated by the micro-electrode technique, are, like those of the frog's eye[2], of three types: pure on-elements discharging merely to onset of illumination, pure off-elements inhibited by light and discharging merely to cessation of illumination, and on-off-elements combining the two properties. If a polarizing current of some 0·7–1·0 mA. is passed through the retina between electrodes stuck in vertically into the nasal and temporal cavities outside the bulb, it is possible to elicit on- and off-effects also by polarization[3]. In such experiments it is necessary always to place the micro-electrode in the same part of the retina, so as to preserve a constant relation to the polarizing source. Threshold responses to polarization can be measured with an accuracy of 5 per cent. In the following description of the polarities of the retinal elements, the terms 'cathodal' and 'anodal' refer to threshold responses at the nasal polarizing electrode.

The pure on-elements reproducing the simple receptor properties respond to cathodal stimulation with an on-effect. An increase of current strength by some 30–40 per cent is necessary to elicit the anodal off-effect (as in many peripheral nerves). The more complex pure off-elements (inhibited by light) have, however, opposite polarity. They respond to the threshold cathodal stimulation with an off-effect. Current reversal, *without increase of strength*, brings forth the anodal on-effect that light cannot elicit. The on-off-elements (80 per cent of the population[4]) respond with a threshold on-effect to either cathode or anode. Those that give cathodal on-effects respond to the anode with an off-effect; those with anodal on-effects respond to the cathode with an off-effect. The elements with anodal on-effects (cathodal 'off') are highly off-sensitive when tested by illumination (high off/on ratio); those with cathodal on-effects are mostly on-sensitive when tested by threshold illumination (low off/on ratio). Cathodal and anodal effects again occur at the same current strength. Except for the electrical symmetry of all the on-off-elements, a greater on-sensitivity thus makes them behave more like pure on-elements, and a greater off-sensitivity makes their properties exactly like those of the pure off-elements. This statement is based on measurements on 71 well-isolated on-off-elements.

In a very large material of isolated spikes the off/on ratio (to light) has varied from 0·001 to 10·000. This enormous variation is coupled with differences in colour sensitivity of the on- and off-components of the on-off-elements[4,5]. These two facts can only be explained by assuming the off-path to start in different receptors and join the direct on-path over internuncial neurones such as amacrines and horizontal cells[4]. The path that is inhibited by light and set free by cessation of illumination is therefore an indirect path to the fibre isolated by the micro-electrode. The polarization results can accordingly be explained in the following manner: the indirectly excited path turns its anode (source) towards the direct path and blocks it, with consequent release at 'off'. With respect to the polarizing electrode, this off-effect will be cathodal. Current reversal leads to indirect excitation (on-effect) at the same converging focus, because in this case the indirect path has turned its cathode (sink) towards the direct path. With respect to the polarizing electrode this means an anodal on-effect. The inner stimulus, however, is cathodal. Hence the perfect electrical symmetry. The anodal and cathodal foci may generate slow potentials of opposite sign, as in the isolated axon of *Sepia*[6], because it is well known that excitation and inhibition in the retina are accompanied by opposite slow potentials[1]. Inhibition is thus a function of the existence of an indirect path which can be picked out by its opposite polarity in the polarization test, and which responds to illumination with a block, followed by an off-effect when the light is turned away. The instantaneous character of the inhibition, when compared with excitation, is due to the rapid establishment of the electrical field in the short axons of the amacrines and horizontal cells which serve as 'internal commutators'. The on-off-elements are a mixture of direct and indirect paths and thus combine anodal and cathodal responses.

Colour Sensitivity, Contrast and Polarity of the Retinal Elements

SINCE the time of Purkinje and Ritter, it has been known and often confirmed that a galvanic current passed through the eye elicits a sensation of bluish-violet when the electrode on the bulb is an anode, of greenish-yellow when it is a cathode. Kravkov and Galochkina[1] have recently shown that the anodal pole (on the eye) enhances the sensitivity to short wave-lengths and depresses that to long wave-lengths, whereas the cathodal pole has opposite effects. In view of the results on different polarity in retinal elements isolated by the micro-electrode technique, reported above[2], it was thought to be of interest to combine polarization of the retina with measurements of the colour sensitivity of such elements. The micro-electrode technique and the cat's eye were used, as above[2]. The strength of the current was 1·0 mA.

The pure on-elements (cathodal 'on'[2]) responded as shown in Fig. 1. Cathodal polarization increased the sensitivity to short wave-lengths; anodal polarization caused a corresponding but smaller depression. The majority of the pure on-elements in the cat's eye are blue- and green-sensitive[3]. The pure off-elements, which have opposite polarity[2], gave an increase in the long wave-lengths during cathodal polarization, with a corresponding depression during anodal polarization (Fig. 1). The majority of these elements are actually red-sensitive[3]. The on-off-elements vary a great deal in colour sensitivity,

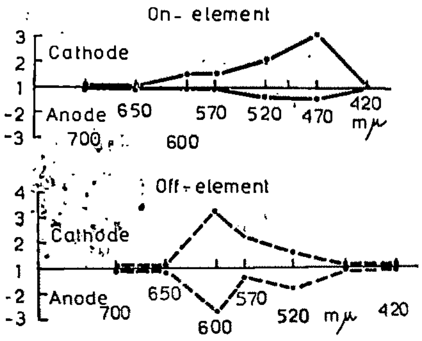

Fig. 1

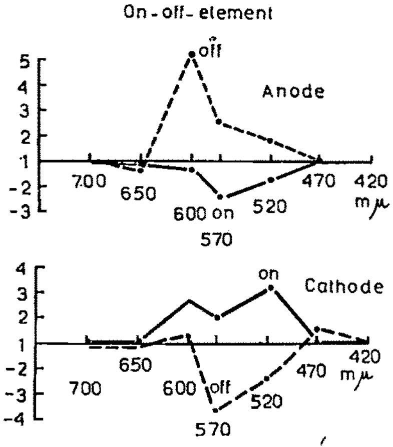

Fig. 2

Figs. 1 and 2. THE ENHANCEMENTS (POSITIVE ORDINATES) AND DEPRESSIONS (NEGATIVE ORDINATES) DURING POLARIZATION OF AN ON-ELEMENT, AN OFF-ELEMENT AND AN ON-OFF-ELEMENT AS MULTIPLES OF THRESHOLD BEFORE POLARIZATION. ABSCISSÆ: WAVE-LENGTHS

consisting as they do of narrow modulator bands in different regions of the spectrum[4]. Granit's colour work on this retina[4] was based on the on-components of these, the most common, elements (80 per cent in the cat's retina[3]). In accordance with this, the on-off-elements also responded very differently to polarization. Maxima and minima were found in various spectral regions, and sometimes they were of a very large order, for example, five times in 600 mμ in one specimen (see Fig. 2). The upper curves for this on-off-element refer to anodal polarization. The off-component had a maximum of enhancement in 600 mμ, the on-component a maximal depression in 570 mμ. During cathodal polarization (lower curves) the on-component had a maximum of enhancement in 520 mμ: the off-component a maximum depression in 570 mμ. This particular element was chosen in order to illustrate how the combination of polarization with a test of the spectral sensitivity provides a new method by means of which colour properties and the organisation of colour contrast can be clarified simultaneously. The contrast mechanism only requires that the on- and off-components of a number of elements be initiated by receptors from 'contrasting' regions of the spectrum which, even in the cat's eye, is quite often the case. Factors of great importance seem to be the off/on ratio at the threshold of illumination[3] and polarity[2].

In this first survey only the wave-lengths marked in the figure were tested on sixteen elements. The most common maxima and minima were, in 520, 600, 470, 570 mμ, in the order enumerated. Despite the limited number of wave-lengths tested, it is seen that there is good agreement with the spectral loci of Granit's modulators in the cat's eye[4]. In particular the red modulator with maximum around 600 mμ was easy to detect by this new method on account of the large enhancements and depressions that it (when present) underwent during polarization.

A New Protein from Ovalbumin

A few months ago when working up slops of salt-free iso-electric ovalbumin solutions from half a year of experiments, we made the surprising observation that the protein, when crystallized with ammonium sulphate, appeared as beautiful rectangular plates instead of the usual flat cigar-shaped needles. We did not at that time observe any infection of the solutions either by bacteria or moulds; but since urea was present and no antiseptics had been added, infection was a factor to be reckoned with even at the low temperature (1°) at which the protein had been stored. A further perusal of our stock of old dialysed ovalbumin solutions in the refrigerator revealed six samples, one to two years old, three of which had been stored with toluene, three without. Only the latter were infected, two with bacteria and one with moulds (and bacteria ?), and upon crystallization they gave a good (60 per cent) yield of plates. All attempts to isolate plates from the former solutions were in vain.

On the basis of these experiments it became highly probable that some—not very specific—bacterial enzyme was active in the formation of 'plate' protein. We were able to test this hypothesis by means of a dry powder of bacterial enzyme from *Bacillus subtilis*, kindly furnished us by Nordisk Insulin Laboratory. After 5 hours action of 10 mgm. of this dry powder upon 1 gm. of dialysed ovalbumin in 100 ml. water at *p*H 6·5, 0·9 gm. of the protein could be isolated as plates. At the same time, as little as 1 per cent of the protein nitrogen had become soluble in 10 per cent trichloroacetic acid. Hence it appears that we have to do with a practically complete transformation of one protein into another.

Processes of protein transformation are known from the field of enzyme chemistry; but it seems to us of considerable interest that a well-established protein like ovalbumin can be enzymatically modified without serious degradation. As mentioned above, the enzyme is scarcely specific for *Bacillus subtilis*, and investigations of different sources of enzyme, especially the hen's egg itself, are in progress. Crystalline trypsin has already been tried with negative result.

The following data concerning the process and its participants have been collected.

The enzyme (prepared from the autolysed bacteria by alcohol precipitation) is thermolabile, and is rapidly decomposed at *p*H below 4, even at room temperature. At *p*H 10 it is destroyed more slowly.

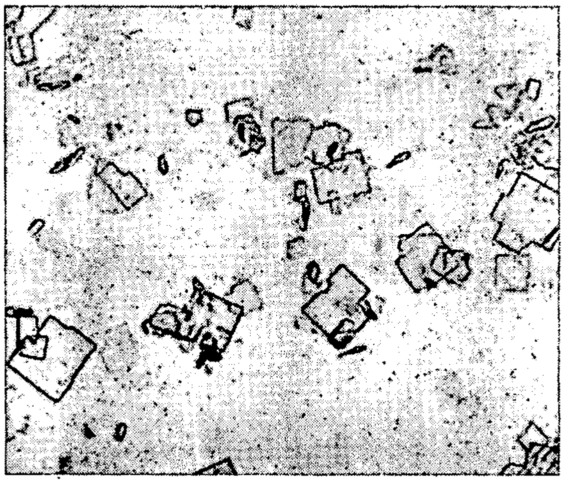

PLATE-ALBUMIN. × 475

The plate-albumin crystallizes very easily in the *p*H region 5–5·6, ammonium sulphate concentration 35–40 gm. per 100 gm. water. In mixtures with normal ovalbumin, both plates and needles will crystallize if the ratio normal/modified protein is below 0·5. The plates are markedly birefringent.

The protein seems to be much more unstable in acid solution (between *p*H 3 and 4·8) than ovalbumin, but quantitative experiments have not been carried out. It can be dialysed and recrystallized with ammonium sulphate and is extremely soluble in water (> 30 per cent). It is denatured by heat like ovalbumin.

The solubility in ammonium sulphate in the *p*H region 5–5·6 is much higher than that of ovalbumin, a circumstance that can be utilized in the determination of the amount of plate protein formed. A 1 per cent ovalbumin solution of *p*H 6·5 will give the first slight turbidity at an ammonium sulphate concentration of 37, while a similar solution of plate protein will remain clear until the ammonium sulphate concentration is 41. The table shows the results of an experiment with active and boiled enzyme (concentration of enzyme 0·01 per cent, temperature 20°).

Time (hr.)	Ammonium sulphate concentration at beginning of turbidity	
	boiled	active
0	37·0	37·5
0·5	,,	40·0
1	,,	40·6
2	,,	41·0
4	,,	41·1

As regards previous observations of a similar nature, we may refer to a paper by MacPherson, Moore and Longsworth[1], in which an ovalbumin component denoted A_2 (and characterized by its mobility in the electric field) was reported to increase in amount at the expense of another (named A_1) during storage with toluene of salt-free, iso-electric ovalbumin solutions at 4–6° for several months. It is premature to discuss the possible relation of this observation with our own. We have submitted a sample of our modified protein to Dr. Longsworth, who has kindly consented to investigate it in the electrophoresis apparatus.

Urea Synthesis in Mammalian Liver

IN earlier experiments[1] it was noted that isolated rat liver can remove much more ammonia from the nutrient medium than can be accounted for by the formation of urea. We have investigated the reactions, other than urea synthesis, which cause a disappearance of ammonia in liver tissue.

The discrepancy between the amounts of ammonia removed and urea formed was especially large in homogenized liver, where the synthesis of urea was found to be virtually abolished (except when relatively high concentrations of ornithine or citrulline were added), while ammonia was still rapidly removed. The highest rates of ammonia utilization in liver homogenates were observed when α-ketoglutarate, or substances known to yield α-ketoglutarate, were present. With α-ketoglutarate the utilization of ammonia also occurred anaerobically. It was found to be accompanied under anaerobic conditions by the formation of approximately equivalent amounts of glutamic acid:

$$\alpha\text{-ketoglutarate} + NH_3 \xrightarrow{-H_2O+2H} \text{glutamic acid.} \quad (1)$$

This reaction has already been observed in extracts of liver and other tissues by v. Euler, Adler, Günther and Das[2] and by Dewan[3]. The amounts of α-ketoglutarate removed were greater than those required for reaction (1); the excess was largely accounted for by the formation of succinate and carbon dioxide. In many anaerobic experiments the data were roughly in agreement with the equation:

$$2\ \alpha\text{-ketoglutarate} + NH_3 = l(+)\text{glutamic acid} + \text{succinate} + CO_2. \quad (2)$$

Thus the reductive amination of one molecule of α-ketoglutarate is coupled with the oxidative decarboxylation of a second molecule of α-ketoglutarate. In other anaerobic experiments, the yields of succinate were considerably lower than that of glutamic acid. In these cases other oxidative reactions, in addition to the oxidative decarboxylation of α-ketoglutarate, must have taken place. Oxidations which can be coupled with reaction (1) are

$$\text{isocitrate} \xrightarrow{-2H} \alpha\text{-ketoglutarate} + CO_2$$

$$\beta\text{-hydroxybutyrate} \xrightarrow{-2H} \text{acetoacetate}$$

as was already found by Adler, v. Euler, Günther and Plass[4] and by Dewan[3].

Reaction (2) has earlier been reported to occur in *slices* of kidney and in minced heart muscle[5]; but it had not been found in slices of liver. In sliced liver, in contrast to homogenized liver, the rates of the reactions (1) and (2) are extremely slow and often negligible, $Q^{N_2}_{\text{Glutamic acid}}$ being usually less than 1 (see also Bach[6]). In rat liver homogenates $Q^{N_2}_{\text{Glutamic acid}}$ can exceed 30. The rate of reaction (1) is increased by adenosine triphosphate.

We are prompted to communicate these results at this stage because of the recent discovery by Cohen and Hayano[7] of the formation of arginine from citrulline and glutamic acid in rat liver homogenates:

$$\text{citrulline} + \text{glutamic acid} \rightarrow \text{arginine.} \quad (3)$$

Cohen and Hayano come to the conclusion that "glutamic acid appears to be an obligatory intermediate in the introduction of ammonia at the citrulline–arginine step of the urea cycle". Our results supplement the experiments of Cohen and Hayano: reaction (1) is obviously the mechanism providing the glutamic acid for interaction with citrulline.

The reaction citrulline + ammonia → arginine thus resolves itself into two stages, namely, reaction (1) followed by reaction (3).

This mechanism of arginine formation was already considered earlier[8] as a possible step in the synthesis of urea, as both reactions were known to occur in kidney cortex[7,9]; but it was rejected for liver[8] because the rates of both reactions were found to be negligible in rat liver slices. It now appears that the inability to demonstrate reactions (1) and (3) in liver slices is due to the limited permeability of the liver cells for α-ketoglutarate and glutamic acid. This is somewhat unexpected, for these two substances readily enter kidney or brain slices, to judge from their effects on tissue metabolism in slices of these tissues. In kidney cortex the rates of the reactions (1), (2) and (3) are about the same in sliced and homogenized material.

Reactions (1) and (2) also occur in pigeon liver homogenates, $Q_{\text{Glutamic acid}}$ exceeding 40. It is likely that this reaction is a link in the synthesis of hypoxanthine from ammonia in pigeon liver.

Two Features of the *Plesianthropus* Skull

THE skull of *Plesianthropus* which we discovered on April 18 is in almost perfect condition; but being the skull of apparently a middle-aged female, some of the sutures are closed and their positions difficult to determine. Still, many can be made out. We hope within a few months to be able to send for publication a complete account of the skull; and when this is published the *Plesianthropus* skull will be almost as satisfactorily known as that of man or any of the living apes. As this complete account will probably be published to the world in less than a year, it will be unnecessary to give preliminary accounts of many of the interesting features; but there are certain points which some English anatomists consider as of very great importance, and we will give here a short account of two characters which will be sufficient to prove that *Plesianthropus* is not just a chimpanzee, but a being of considerably more importance.

Prof. Wood Jones, in his delightful book, "Man's Place Among the Mammals", devotes a few pages to the structure of the floor of the anterior fossa of the cranial cavity, and gives a number of diagrammatic drawings to show that man is in this part of his anatomy not very closely allied to the higher anthropoids, though a little more allied to the orang. In this we agree with him.

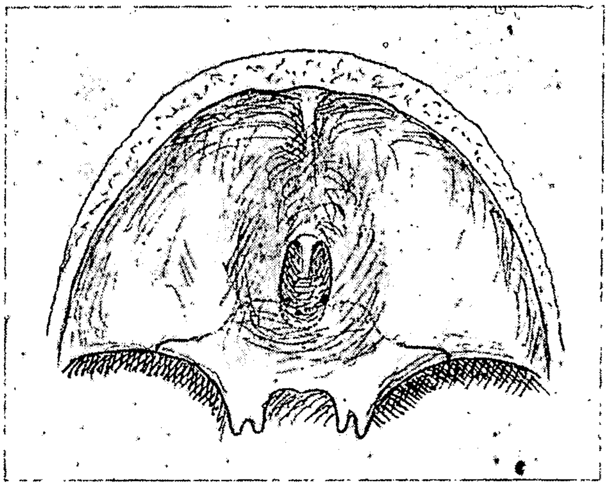

Fig. 1. ANTERIOR FOSSA OF SKULL OF *Plesianthropus transvaalensis* BROOM, ♀. ¾ NATURAL SIZE

In man the relations of the sphenoid to the ethmoid and frontals differ considerably in different specimens, but only rarely do the frontals meet behind the cribriform plate. In the gorilla and most chimpanzees, the frontals meet; but in the orang and the gibbon the sphenoid and the ethmoid usually articulate on the floor of the fossa. In most Old World monkeys the frontals also meet.

In *Plesianthropus* the condition is very similar to that in man. The fossa is large and extends much in front of the cribriform plate. The sphenoid forms a large part of the floor of the fossa. The sutures at the outer parts can be clearly seen, but cannot be determined with certainty in front. There seems little doubt, however, that the sphenoid articulates with the ethmoid, and that behind the cribriform plate the frontals are wide apart.

We have drawn the cribriform plate as it is in the specimen, and we indicate with a little hesitation what we regard as its anterior and posterior borders. There is a small but quite distinct crista galli.

An interesting point is that the lesser wings of the sphenoid with the frontals form as in man very marked outstanding bony ridges which divide the temporal fossæ from the anterior. This is a human character which we cannot match in any anthropoid skulls we have seen—gorilla, chimpanzee, orang or gibbon.

Another interesting point is the structure of the orbit. In man the inner wall of the orbit is mainly formed by the lacrimal, the frontal, the ethmoid and the maxilla, and the ethmoid has a long articulation with the lacrimal. In the higher anthropoids the frontals usually meet the maxillæ and "the planum

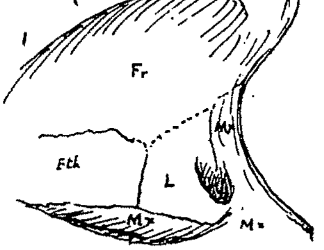

Fig. 2. INNER WALL OF THE ORBIT OF *Plesianthropus transvaalensis* BROOM. NATURAL SIZE

orbitale of the ethmoid is reduced". In the orang and the gibbon a large planum orbitale articulates in front with the lacrimal, as in man. The figure we give of the orbital wall in *Plesianthropus* shows a condition almost exactly as in man.

We are here not at present concerned with the question of whether man and the Australopithecinæ have arisen from an early anthropoid, or a pre-anthropoid, or an Old World monkey or a tarsioid; but we think the evidence afforded by this new skull of *Plesianthropus* shows that the Australopithecinæ and man are very closely allied, and that these small-brained man-like beings were very nearly human.

Conversion of Carbon Dioxide to Acetylene on a Micro Scale

As a preliminary to future attempts to synthesize, on a very small scale, biologically important compounds containing radioactive carbons C^{14} or C^{11}, we have developed a technique for the conversion of small quantities of carbon dioxide to acetylene. Both carbon isotopes[1,2] are most conveniently prepared in the chemical form of carbon dioxide, but acetylene is a better starting substance for a number of syntheses. In our experiments, pure barium metal was heated in a stainless steel vacuum furnace of special design in the presence of carbon dioxide, which was absorbed with the formation of barium carbide.

Quantities of ordinary inactive carbon dioxide varying from 50 to 500 microlitres at N.T.P. were measured in a McLeod gauge and transferred through a high-vacuum apparatus to the stainless steel furnace containing about 40 mgm. of barium metal which had been scraped as clean as possible before weighing. The furnace was heated to 600° C. for 5–10 min. and all the carbon dioxide disappeared. The furnace was cooled and its contents dissolved in water. The gas mixture obtained was found to consist (apart from water vapour and hydrogen) of acetylene, ammonia formed from barium nitride and a trace of ethylene which never exceeded 2 per cent of the total C_2 hydrocarbons.

Acetylene was separated by passing the mixture through a rough drying trap at $-78°$ C. and then adsorbing ammonia, water vapour, acetylene and the trace of ethylene from the hydrogen stream on to active charcoal at $-78°$ C., the hydrogen being pumped away. The temperature of the charcoal was raised to 0° C., when an appreciable proportion of the acetylene (and ethylene) was desorbed: the acetylene was finally condensed into a trap connected with the McLeod gauge. No ammonia or water vapour is desorbed at this temperature during the ten minutes necessary for practically all the acetylene to be recovered.

The results were as follows:

Expt. No.	Carbon dioxide used (μl. at N.T.P.)	Acetylene (+ ethylene) found (μl. at N.T.P.)	Acetylene blank (μl. at N.T.P.)	Yield %
21	335	178	14	98
22	273	133	12	89
23	300	140	3	91
24	305	140	3	90
*25	62	25·5	1·1	79
27	558	265	3	94
28	566	260	2	91
*29	50	21·5	1·8	79

* From these and other experiments it appears that lower yields for small quantities of CO_2 are to be expected.

Stainless steel was found to be the most satisfactory furnace material tried. From mild steel relatively large amounts of acetylene were produced in blank experiments, and a fused silica envelope fitted with a nickel thimble was found, after it had been used with calcium and barium metals, to absorb carbon dioxide when hot even when no calcium or barium was present. In carrying out the absorption of carbon dioxide by barium metal in the stainless steel furnace it was found that when the pressure at which the gas was admitted was less than about 10^{-1} mm. of mercury, the yield of acetylene was variable and only about 45 per cent. Good yields were obtained when the carbon dioxide at its full pressure was admitted to the furnace before raising the temperature above 400° C. It was further found that if acetylene, ammonia and water are condensed together in the presence of mercury, acetylene is lost very rapidly on warming up the mixture. This may be due to the formation of mercury acetylide. Losses due to all the above causes are avoided by following a standard procedure.

For the identification of all the gases involved in these experiments, physical and chemical methods were applied. Vapour pressures at low temperatures were measured, and individual gases were absorbed from mixtures with standard reagents. Acetylene in particular was absorbed in a paste of cuprous chloride and caustic potash solution with the formation of red copper acetylide.

The conversion of carbon dioxide to acetylene can be carried out in about half an hour. This may make possible the synthesis of many compounds containing C^{11} of half-life 20·5 min.

Full experimental details of this work will be published elsewhere.

We wish to thank Prof. W. H. Linnell for his interest and support, many others for helpful conversations, the Research Laboratories of the General Electric Co., Ltd., for a specimen of very pure barium metal, and to acknowledge generous grants from the Therapeutic Research Corporation, the Royal Society, the Medical Research Council and the Central Research Fund of the University of London. A New Indicator for Iodometric Analysis

It is well known to analysts that starch is very far from being an ideal indicator for iodine, and the disadvantages from which it suffers are not all avoided by the use of an acid-solubilized starch. It will be agreed that the chief disadvantages attending the use of starch are: (1) the insolubility of starch in cold water; (ii) the instability of starch dispersions in water, in consequence of which a stock solution soon deposits a flocculent precipitate of retrograded starch; (iii) that starch gives with iodine a water-insoluble complex, the formation of which precludes the addition of the indicator early in the titration;

and (iv) the 'drift' of end-point which is particularly marked when the solutions used are dilute.

In the course of our investigation of the glycollic ethers of starch and of its components, amylose and amylopectin, we encountered a derivative which has proved to be eminently suitable as an indicator in iodometric titrations. This derivative is the sodium salt of a starch glycollic acid in which the ratio, glycollic acid units/glucose units, is approximately 1 : 10. This derivative, which is conveniently described as 'sodium starch glycollate (1 : 10)', has almost the same iodine-staining power as starch itself, and as an iodometric indicator it possesses none of the disadvantages mentioned above. It is a non-hygroscopic white powder which dissolves, with ease, in cold water to give a clear solution. The only factor limiting the concentration obtainable in cold water is the viscosity of the resulting solution. The solutions are completely stable, no retrogradation occurs, and they may be kept for months without the faintest turbidity appearing. The glycollate does not form a water-insoluble complex with iodine, and in consequence the indicator may be added at any stage in a titration. The end-point is very sharp: with an excess of iodine (as at the beginning of a titration with thiosulphate) the colour of the solution is green, and as the titration proceeds and the iodine concentration diminishes, the colour changes gradually to pure blue, which becomes intense just before the end-point is reached. The end-point is sharply reproducible and no drift is observed even in highly dilute solutions.

Sodium starch glycollate maintains its superiority over starch as an indicator in all the types of iodometry examined, as, for example, in the estimation of reducing sugars by the Shaffer–Hartmann or Somogyi methods or in the estimation of copper or arsenic.

Preparation. A dispersion of starch (10 gm.) in water (160 c.c.) is stirred with 50 per cent sodium hydroxide solution (30 c.c.), and to the mixture is slowly added sodium monochloroacetate (5 gm.) in water (20 c.c.) at 50° C. After neutralization with acetic acid, the solution is dialysed for three days in a 'Cellophane' bag against running water. Thereafter, the sodium starch glycollate is precipitated from solution by the addition of an excess of alcohol, and its purification completed by its extraction in a Soxhlet apparatus with water-alcohol (10 : 90 by volume). The glycollic acid content is estimated by precipitation of either the copper or the silver salts.

We wish to record our thanks to Lieut.-Colonel F. W. Pinkard, who carried out most of the comparative iodometric titrations.

Metal–Ammonia Solutions

A solution of sodium in liquid ammonia is known[1] to give a eutectic, m.p. −110° C. We have now determined the melting points for the eutectic of potassium, ~ −157° C.; of lithium, ~ −185° C., and of calcium, ~ −90° C. The solids separating from the frozen eutectic solutions of potassium and sodium are undoubtedly ammonia and the metal; the latter can be seen as silvery crystals. From frozen calcium solutions a brass-like solid separates, which certainly contains the hexammoniate known to be stable even at room temperature[2]. From the lithium solution a similar solid is obtained, and it therefore seems probable that it also forms an ammoniate. A resemblance between calcium and lithium can also be found in the short time (small amount of heat) required in both cases to melt the eutectic compared with that for sodium or potassium. This is understandable if one remarks that the heat taken up in the process goes chiefly in melting ammonia (which has a very high latent heat), since this, in the ammoniates, is already associated to some extent with the metal, and very little extra is required to form the eutectic solution. The resemblance extends to chemical reactions, since a concentrated solution of lithium in ammonia, which is stable and has a very low vapour pressure at room temperature, can be used to hydrogenate benzene rings, and exerts some demethylating effect on methoxyalkylbenzenes (compare calcium hexammoniate)[3].

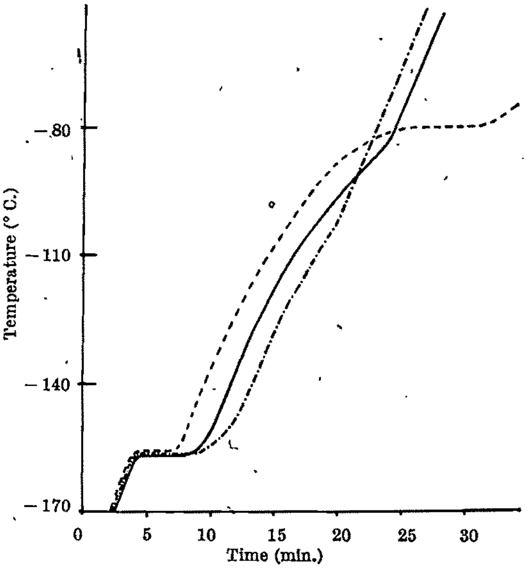

Fig. 1. Potassium–ammonia solutions. Experimental points, all at ½-min. intervals, lie closely on curves and have been omitted for clarity. – – –, 6·3 atomic %; ———, 11·8 atomic %; —·—·—, 14·3 atomic %

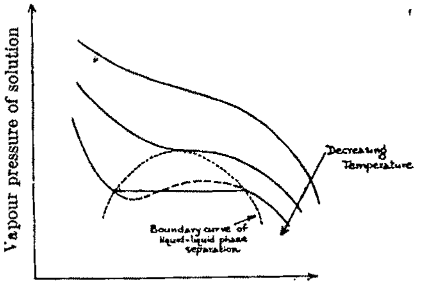
The constitution of the ammoniates, which have metallic properties, is not clear. It seems probable that they are lattice 'compounds', and the ammonia is not necessarily bound by complete electronic bonds. Their non-formation with potassium and sodium may be due to inability to form a suitable lattice; but from the similar appearance and behaviour of the solid ammoniates and the very concentrated solutions of all the metals, it is probable that strong association between ammonia and the metal takes place even in the liquid. This would explain the extremely sharp drop in the vapour pressure of solutions as the concentration approaches that of the eutectic. This drop is manifested as a very great depression of the melting point of solid ammonia in contact with the solution. We have been able to construct the portion of the phase curve for concentrated solutions (below the melting point of pure ammonia) from the warming curves (Fig. 1), which show a slight, but easily discernible, rise in slope at the point where the solid ammonia finally disappears, the curve hereafter becoming practically a straight line. This portion of the phase curve represents the solubility of ammonia in the metal.

The upper flat step in the warming curve for dilute solutions represents the melting point of solid ammonia at a temperature which remains constant because of the appearance of two liquid phases of fixed concentrations. This phase separation is well known for sodium[1] and calcium[2]; our results confirm it for potassium with an upper consolute point at ~ −74° C., but show that it is very unlikely for lithium. Kraus[4] has stated that the deviations of the vapour pressure of the solutions from Raoult's law (shown diagrammatically in Fig. 2) arise as a result of the phase separation, and not as a result of aggregation of the solute. It is clear, however[5], that the phenomenon of separation into two liquid phases in equilibrium is to be regarded as a direct consequence of the deviations from Raoult's law. Bowden has pointed out: "this is reminiscent of the van der Waals p—v curve . . ." It appears to us that, in fact, a first quantitative approximation may be derived by using the van der Waals' modification of Boyle's law in Van't Hoff's law of osmotic pressure, deriving the constants in the equation from known data at the upper consolute point. The existence of associative forces would be expected to lead to aggregation of the solute molecules, and this is shown even at the boiling point by an apparent rise in molecular weight for increasing concentrations above a low value. If this association were great enough, it could explain the rise in vapour pressure in the intermediate region which would occur in absence of liquid-liquid phase-separation, and which does, in fact, produce the separation into a more concentrated and a more dilute phase. The rapid fall near the eutectic concentration can be attributed to almost complete binding of the ammonia.



Vapour pressure of solution
Decreasing Temperature
Boundary curve of liquid-liquid phase separation
Concentration

Fig. 2

It would appear that similar phenomena should occur with the other alkali and alkaline earth metals. A more detailed discussion of this work will be published elsewhere.

Isomorphic Form of Urea Picrate

Urea picrate is described by Smolka[1] as having m.p. 142° C. and formula $CH_4ON_2,C_6H_3O_7N_3$ (form *A*). A new isomorphous form with m.p. 275° C., and the same formula (form *B*) is here described.

Preparation. Form *A* is prepared by mixing solutions of urea and picric acid. Although various solvents—water, acetone and methyl, ethyl and *n*-propyl alcohols—have been tried, in every case form *A* was precipitated. 4 : 1, 1 : 1, and 1 : 4 molar ratios of urea and picric acid were also tried. Again form *A* was always precipitated.

Form *B* may be prepared in two ways: (*a*) Repeated recrystallization. After several recrystallizations from alcohol, the melting point of form *A* is raised to 170° C. or higher. One or two further recrystallizations then raise the melting point to about 255° or 260° C. (*b*) Chromatography. If an alcoholic solution of form *A* is passed down a sand column and then concentrated, the resulting crystals usually melt well above 200° C. A further recrystallization is usually sufficient to raise the m.p. to 255°–260° C. In these preparations of form *B*, two points are noteworthy. Once the melting point is raised above *c.* 170° C., little difficulty is experienced in raising it to 255–260° C. Several further recrystallizations are necessary to raise it to 275° C.

Crystallography. Crystals of both forms were examined by Dr. C. O. Hutton, of the Geology Department here. He reports that while form *A* is monoclinic or possibly triclinic, form *B* is orthorhombic.

Analysis. Analytical figures obtained were as follow:

Found	C, 29·1% ;	H, 2·58% ;	Urea N, 9·7, 9·7, 9·9, 10·1%
Calc. for			
$CH_4ON_2,C_6H_3O_7N_3$	29·1	2·42	9·7
$CH_4ON_2,2C_6H_3O_7N_3$	30·1	1·93	5·4

Kjeldahl analyses for total nitrogen even on the same sample gave results ranging from 21 to 24 per cent. While the carbon and hydrogen values agree closely with those calculated for $CH_4ON_2,C_6H_3O_7N_3$, since the figures for the two formulæ are so close, urea nitrogen was estimated by the urease method.

The unreliability of the melting points of picrates is notorious. The case of urea picrate is just another example. It is felt that to prevent others being led astray, this abnormality should be reported.

I have to thank Mr. C. L. Carter, senior lecturer in chemistry at the University of Otago, for the micro-determination of carbon and hydrogen.

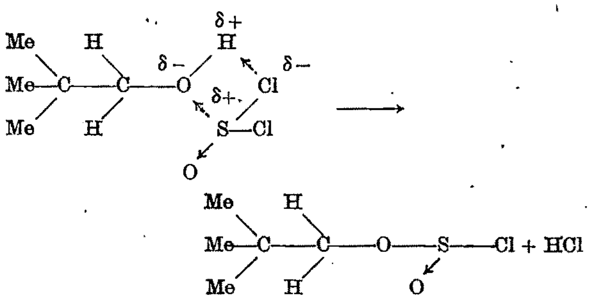
Neo-pentyl Alcohol and Steric Hindrance

Whitmore and Rothrock[1] showed that the hydroxyl group in *neo*-pentyl alcohol has remarkable resistance against replacement by a halogen atom through the agency of thionyl chloride and phosphorus tribromide. Dostrovsky, Hughes and Ingold[2] attribute this to steric hindrance to 'end-on' approach to the α-carbon atom. Whitmore and Rothrock, however, leave the impression that *neo*-pentyl alcohol does not interact at all with these reagents, and indeed state: "The inactivity of neopentyl alcohol to heat and reagents has been demonstrated"; but the work of Gerrard[3] enabled us to predict probability of easy 'broadside' approach.

neo-Pentyl alcohol and thionyl chloride quite readily gave us the chlorosulphinate, ROSOCl, and in the presence of pyridine, the sulphite, R_2SO_3, in excellent yields. Phosphorus trichloride, and tribromide in the absence of pyridine, produced the halogenophosphites, for example, ROPCl$_2$, while in the presence of pyridine, an *ester* of phosphorous acid was readily obtained. Phosphorus oxychloride in the presence of pyridine gave an *ester* of phosphoric acid. We conclude that *neo*-pentyl alcohol very readily responds to 'broadside' four-centre attack; for example:



We find that the hydroxyl group in αα-dimethyl-*neo*-pentyl alcohol, a tertiary alcohol, is replaceable by halogen through the interaction with these reagents, in accordance with the theory of substitution developed by Ingold and Hughes.

Details of these experiments are being prepared for publication.

Precipitating Effect of Cationic Detergents on Soluble Starch

CATIONIC detergents, the bactericidal property of which was discovered by Domagk (1938), have a precipitating effect on certain proteins (Kuhn–Bielig, 1940). Since this precipitation occurs at high pH values, it is evident that it is due to salt-like bonds between the positively charged groups of the detergent and negative groups of the proteins. It is not surprising, therefore, that similar precipitates were observed when solutions of polysaccharidic acids, such as agar-agar, heparin, or gum arabic, were added to those of 'Desogen' (Geigy), that is, methyl-phenyl-dodecyl-trimethyl-ammonium methosulphate. In the course of these experiments it was observed, however, that polysaccharides *devoid of acidic groups* were also precipitated by 'Desogen'. Thus soluble starch (Merck, Schuchardt), dissolved in distilled water or in salt solution at different pH values, gave distinct precipitates. Two minima of turbidity were observed, one at a pH of 14 and another close to pH 7 (see table).

Each of the test tubes used in this experiment contained 160 mgm. of soluble starch, 40 mgm. of 'Desogen' and 20 ml. of 0·1 M borate buffer solution. The intensity of the turbidities was measured nephelometrically. Then the precipitate brought about at a pH of 9·2 was centrifuged, dried and weighed. The quantity of the other precipitates was calculated by comparison of this value with the nephelometric values.

pH values:	0(=N HCl)	1	2·3	6·5	8·2	9·2	11	14(=0·1 N NaOH)
Precipitates (mgm.):	36·6	23	4·6	5·5	34	50	52	8·8

When starch and 'Desogen' were dissolved in distilled water, the amount of precipitate was negligibly small; a distinct precipitate was observed in isotonic and hypertonic solutions of sodium chloride.

The amount of precipitate depends on the relative concentration of both components. Maximal precipitates were obtained with mixtures containing 20 mgm. of 'Desogen' with 80 mgm. of soluble starch in 10 ml. of the buffer solution. The turbidity and the precipitates began to disappear when the solutions were heated to 30–40°, and the solutions became entirely transparent at 70°; on cooling, the precipitate appeared again. Moreover, we observed that the colour reaction of soluble starch given by iodine was inhibited by 'Desogen'. The blue colour was changed to a reddish-violet or to a pale yellow, depending on the amount of 'Desogen' added to the starch solution.

The details of these and other experiments will be published elsewhere.

Muscle-Relaxing Ethers of Glycerol

THE discovery of the useful applications of curare in medicine and surgery has directed attention to other substances which are capable of producing muscular relaxation in man. In 1910, Gilbert and Descomps[1] administered the α-phenyl ether of glycerol to guinea pigs and observed: "Au bout d'un laps de temps variant, suivant la dose injectée, de trois minutes à dix minutes, on voit apparaître un certain degré de parésie des membres, parfois précédée de quelques rares et courtes contractures passagères. Cette paralysie incomplète est toujours transitoire, et sa durée oscille en général entre quinze et trente minutes; une seule fois, elle persista une heure." Launoy[2] studied the action of the same compound and observed a "résolution musculaire" and the antagonism of the drug to strychnine. Muscle-relaxing properties were later and independently observed in several glycerol ethers[3], and one of these, the α-*o*-tolyl ether ('Myanesin'), was found to be effective in man[4]. The present note indicates some of the relationships which have been observed between the molecular structure of glycerol ethers and their muscle-relaxing power. For the purpose of discussion it is useful to consider the molecular median paralysing dose ($P.D._{50}$/mol. wt.) in mgm. per kgm., that is, the mole-fraction of the glycerol ether which is required to paralyse 50 per cent of white mice to which it has been administered subcutaneously.

The presence of the grouping —O—CH$_2$—CROH—CR_2OH appears to be necessary for muscle-relaxing activity. Most of the β- and γ-alkyl derivatives of the α-ethers that we have tested are relatively inactive, as also are a few O-glucosides of active glycerol ethers. Some esters show activity of a low order, but this may be due to hydrolysis following injection. The activity of the α-ethers, *R*O—CH_2—CHOH—CH_2OH, varies greatly with *R*. Beginning with the simplest compounds, the activity increases to a maximum with the introduction of additional groups and then falls. Before maximum activity has been reached, both the nature and orientation of groups are prominent factors in determining activity; but afterwards the introduction of additional substituents causes a fall in potency, and the extent of the change is no longer so characteristic of the added group.

The methyl and ethyl ethers show negligible activity. With increase in chain-length the activity increases to a maximum at C_5 and then falls. The *iso*-butyl and the *iso*-amyl ethers are weaker than their *n*-isomerides in approximately the same degree.

	$P.D._{50}$/mol. wt. × 10^2
Methyl	>2·4
Ethyl	>2·1
Propyl	>1·5
Butyl	1·0
Amyl	0·57
iso-Butyl	1·2
iso-Amyl	0·81

The phenyl ether is more active than any of the alkyl ethers mentioned.

In the aryl series an increase in activity follows the introduction of a single methyl, ethyl, allyl, chloro or bromo substituent, the effect depending on the group and its orientation.

	$P.D._{50}$/mol. wt. × 10^2
Phenyl	0·54
o-Tolyl	0·18
m-Tolyl	0·32
p-Tolyl	0·29
p-Chlorophenyl	0·22
p-Bromophenyl	0·34

In the *p*-alkyl series maximum activity occurs in the *p*-tolyl compound. Each successive addition of —CH_2— reduces the activity by an approximately constant amount.

	$P.D._{50}$/mol. wt. × 10^2
p-Ethylphenyl	0·43
p-Propylphenyl	0·61
p-Butylphenyl	0·80

In the *o*-series, the allyl compound is more effective than the propyl. The activity of each is increased slightly by an additional *o*-methyl substituent, but a *p*-methyl reduces the activity of both in approximately the same degree.

	$P.D._{50}$/mol. wt. × 10^2
2-Propylphenyl	0·58
2-Propyl-4-methylphenyl	0·83
2-Propyl-6-methylphenyl	0·49
2-Allylphenyl	0·35
2-Allyl-4-methylphenyl	0·63
2-Allyl-6-methylphenyl	0·31

Chlorine and bromine, which as single substituents increase the activity of the α-phenyl ether, both decrease the activity of the *o*-allylphenyl and *o*-propylphenyl ethers, and the effect is largely independent of the nature of the halogen or its orientation.

	$P.D._{50}$/mol. wt. × 10^2
2-Propyl-6-chlorophenyl	0·78
2-Propyl-6-bromophenyl	0·48
2-Propyl-4-chlorophenyl	0·85
2-Propyl-4-bromophenyl	0·86
2-Allyl-6-chlorophenyl	0·55
2-Allyl-6-bromophenyl	0·59
2-Allyl-4-chlorophenyl	0·58
2-Allyl-4-bromophenyl	0·58

The above discussion is based on the work of our colleagues, Messrs. B. Baker, N. A. C. Pryce, F. G. Sayer, Miss M. Gayler and Drs. Elliott, Forrest, Maclean and Stephenson.

We desire to express our thanks to the directors of the British Drug Houses, Ltd., for permission to publish this note.

A Recording Surface Balance of the Horizontal Type

A SIMPLE and robust film-pressure meter has been constructed using the principle of the 'Mikrokator'[1,2]. The new instrument has been evolved in collaboration with the inventor of the 'Mikrokator', Mr. H. Abramson, of Messrs. C. E. Johansson, Eskilstuna, Sweden, and is a modification of the standard length-measuring instrument manufactured by that firm.

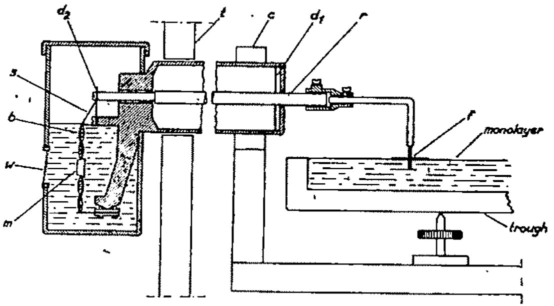

Fig. 1

The construction of the pressure meter is shown in Fig. 1. The pressure to be recorded is applied to the free (right) end of the rod *r*. In the figure a mica float *f* is attached directly to the end of *r*, but other arrangements for transferring the film pressure to the rod may, of course, be used. The rod *r* is supported by two thin slotted steel diaphragms d_1 and d_2. At the left end of *r*, the spring *s* transfers the axial movement of the rod to one end of a thin, spirally twisted, perforated metal ribbon *b*, the lower end of which is fixed. Before mounting in the instrument, the ribbon is placed between fixed supports and the mid-point turned until a desired permanent twist persists. In the instrument, the alteration of the distance between the supports resulting from axial displacement of *r* causes the mid-point of the ribbon with the attached mirror *m* to turn. The mirror moves in a Nujol bath which gives suitable damping. Over the small range of angular deflexion used (about 3°), the movement of the mirror is accurately proportional to the film pressure. There is no friction, and owing to the high mechanical magnification of the instrument the axial movement of *r* with the attached mica float *f* for full-scale deflexion is very small.

In the instrument now in use, which has a range of 60 dynes per cm. and a period of 0·3 sec., this movement is of the order of 0·1 mm. only. The stem of the 'Mikrokator' is held by a clamp *c* (this clamp is attached to the carriage of the recording Wilhelmy – Dervichian balance previously described[3]), and passes through a hole in the wall of the thermostat *t*. The light from a straight-filament lamp is reflected from the mirror *m* and focused on to a cylindrical recording camera which is driven synchronously with the film-compressing barrier by means of a hydraulic drive mechanism (cf. ref. 3). The zero position of the instrument, which is very stable, can be altered by means of an adjustable spring (not shown in Fig. 1) attached to the left end of the rod *r*. The calibration of the instrument may be carried out with an auxiliary torsion balance or by means of films showing distinct phase transitions at known surface pressures. It is possible to construct instruments having a much higher sensitivity than that mentioned above.

The 'Mikrokator' surface balance is at present being used to study phase transitions in condensed monolayers, especially the reversibility of the phase changes on expansion of the film. The vertical type balance is in general not suitable for the study of the behaviour of monolayers on expansion, and we have also encountered certain difficulties, even when using an instrument with symmetrical compression[4], in the study of transitions to the solid *CS* phase in cases when the L'_2 phase is absent, for example, with normal chain primary alcohols, methyl and ethyl esters of normal chain carboxylic acids (for a description of the surface phases found for condensed films of long-chain carboxylic acids see ref. 4).

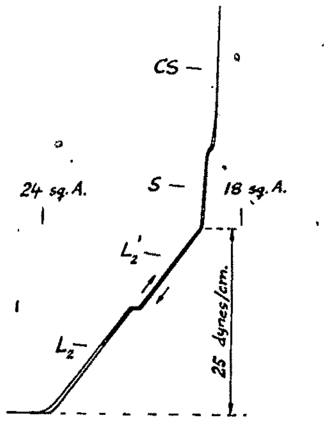

Fig. 2

As an example of the use of the 'Mikrokator' balance, a compression-expansion run of *n*-docosanoic (behenic) acid spread on 0·01 *N* hydrochloric acid at a temperature of 15·2° C. is shown in Fig. 2. The reversibility of the three different phase transitions and of the pressure-area curve in general is clearly demonstrated. In order to obtain curves of the type shown in Fig. 2 the hydraulic drive mechanism previously used[3] had to be redesigned to allow movement of barrier and camera in either direction.

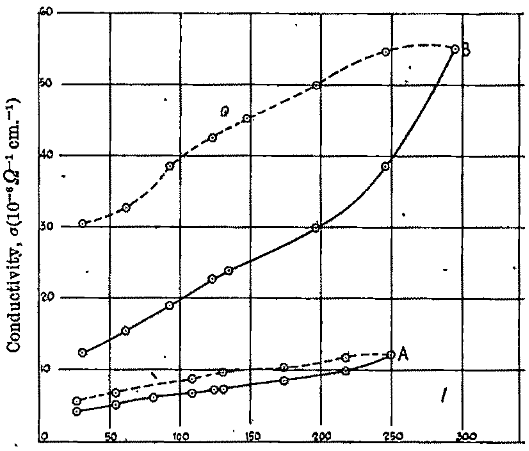
Conductivity Hysteresis of Dust Deposits

THE electrical breakdown of a gap bridged by dust deposits is frequently ascribed to the presence of the dust, but little information on the conductivity characteristics of dust is available. These characteristics were therefore investigated for a typical sample of the following composition: volatile matter (oils), carbon, moisture, 55 per cent; metals and oxides (iron, copper, brass, iron and copper oxides), 36 per cent; residue, complex silicates (clay), 9 per cent.

A conductivity cell of the type described by Maurer[1] was used, and measurements were carried out with the dust compressed to varying degrees corresponding to different conditions of sedimentation.

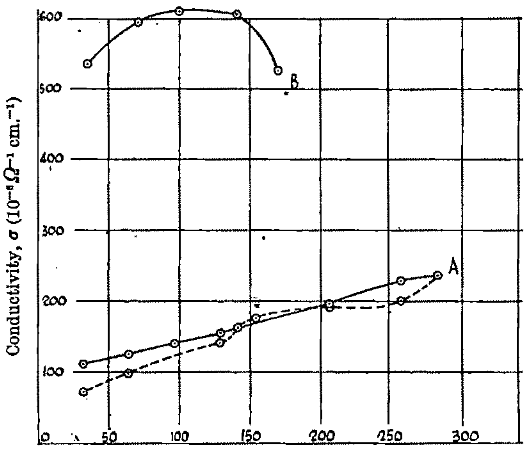
The results are shown in Figs. 1 and 2. Under compressions of the order of 10 lb./sq. in. and 50 lb./sq. in., the dust behaves initially as a symmetrical semi-conductor with the conductivity σ increasing with the applied potential gradient ΔV, according to an empirical expression $\sigma = \beta \Delta V^{\alpha}$ which is derived from a power law proposed by Fairweather[2], α being a constant of the material and β a conductivity factor. Above a critical value of ΔV, σ rises more rapidly. The conductivity characteristic becomes



Potential gradient, ΔV (peak A.C. volts/cm.)

Fig. 1. CONDUCTIVITY HYSTERESIS OF A DUST SAMPLE

Compression: *A*, 10 lb./sq. in.; *B*, 50 lb./sq. in. ΔV increasing, ——— ; ΔV decreasing, - - - -



Potential gradient, ΔV (peak A.C. volts/cm.)

Fig. 2. RELATION BETWEEN CONDUCTIVITY AND APPLIED POTENTIAL GRADIENT OF DUST UNDER HIGH COMPRESSION

Compression: *A*, 100 lb./sq. in.; *B*, 200 lb./sq. in. ΔV increasing, ——— ; ΔV decreasing, - - - -

non-reversible in this region, and decrease of ΔV then leads to conductivity hysteresis. This effect is independent of the direction of ΔV, and thus occurs with both A.C. and D.C. potentials.

Güntherschulze[3] has explained semi-conductivity for 'Silit', a mixture of silica-carbide, graphite and alumina, on the basis of electron acceleration in the nominally insulating particles of alumina, the penetration involving larger particles with increasing ΔV. This mechanism can be applied to compressed dust, which forms a similar material. Fröhlich[4] has shown that, if the dielectric stress on such particles exceeds a critical value, their insulating properties will be destroyed entirely, and the conductivity of a given path thus increased. Dielectric breakdown increases cumulatively with time; but if ΔV is reduced below its critical value after, say, one minute, sufficient nominally insulating particles are left to restore normal semi-conductivity at a higher level. The empirical equation also applies for decreasing values of ΔV. α is not affected by hysteresis, and varies only slightly with increasing compression, but β increases with hysteresis by 32 per cent at 10 lb./sq. in. (Fig. 1, Curve *A*) and by 124 per cent at 50 lb./sq. in. (Fig. 1, Curve *B*), and with compression by 150 per cent between 10 lb./sq. in. and 50 lb./sq. in.

Dèchêne[5] has reported a decrease of contact resistance between particles with increasing compression. This gives rise to a reduced interfacial contact potential and a larger potential gradient across insulating layers, which leads to a more pronounced hysteresis at 50 lb./sq. in. (Fig. 1, Curve *B*). But at high values of compression, conduction tends to become predominantly metallic. The leakage currents are then sufficiently large to cause considerable heating in the sample, and the positive temperature coefficient of the metallic conductors gives rise to a somewhat erratic hysteresis effect at 100 lb./sq. in. (Fig. 2, Curve *A*), and to a falling conductivity at higher values of ΔV at 200 lb./sq. in. (Fig. 2, Curve *B*).

Conductivity hysteresis is thus dependent on the compression of the dust, and it reaches a maximum at a condition of sedimentation which may well be found in dust deposits containing oil and moisture and subjected to intermittent vibration.

Nuclear Thermodynamics and Showers

THE properties of a thermodynamic assembly consisting of atomic nuclei, nucleons, electrons and positrons, at high densities and at temperatures for which $kT \sim mc^2$ (m being the electron mass), have been studied by several investigators[1]; but the application of the results to the problem of the relative abundances of atomic nuclei in the universe has so far met with little success. It is generally recognized, however, following Bohr, that thermodynamical concepts provide a useful basis for discussing the general features of nuclear phenomena.

The purpose of this communication is to point out the possible bearing of the study of such dense, high-temperature assemblies on the phenomenon of the 'explosion' showers associated with cosmic rays. One may, in fact, estimate, on the basis of these ideas, the relative probabilities for the emission of light nuclei from a highly excited heavy nucleus, like those recently observed in the multiple disintegration processes produced by cosmic rays[2]. Further, an elementary calculation allows us to estimate the number of mesons and electrons (positive and negative) in an excited nucleus. In the following table, r denotes the ratio of the meson concentration to the electron concentration (this quantity may be taken as comparable with the ratio of the numbers of mesons and electrons emitted in explosion showers); E denotes the (average) energy per particle (electron or meson); and n the total number of electrons present in a heavy nucleus (mass number, 200).

A Short Method for Calculating Maximum Battery Reliability

THE method devised by Thomson[1] for obtaining test weights which give maximum battery reliability can be simplified to lead to much shorter computation.

The correlation between a set of tests, the a variates, and their second application, the α variates, can be symbolized by the matrix $\begin{bmatrix} R_{aa}R_{aa} \\ R_{aa}R_{aa} \end{bmatrix}$, where, under the conditions set out by Thomson, $R_{aa} = R_{aa}$ and $R_{aa} = R_{aa}$. Treating battery reliability as a special case of Hotelling's battery prediction[2], Thomson finds its maximum value by maximizing $u'R_{aa}R_{aa}^{-1}R_{aa}u$ under the condition $u'R_{aa}u = 1$, where u is the vector of test weights which make battery reliability a maximum. Thomson, therefore, requires to solve the equation

$$|R_{aa}R_{aa}^{-1}R_{aa} - \lambda R_{aa}| = 0 \quad . \quad . \quad (1)$$

for its largest root λ_1. This root is equal to r_m^2, where r_m is the maximum battery reliability and the weights u are in the ratio of the elements of any row of the matrix $\mathrm{adj}(R_{aa}R_{aa}^{-1}R_{aa} - \lambda_1 R_{aa})$.

In the method I now suggest the weights u are the same for both applications of the test battery (ref. 1, p. 359) and battery reliability is given by

$$r = \frac{u'R_{aa}u}{u'R_{aa}u}, \quad . \quad . \quad . \quad . \quad (2)$$

and *maximum* reliability follows by maximizing $u'R_{aa}u$ under the condition $u'R_{aa}u = 1$. We thus require to solve the equation

$$|R_{aa} - \lambda R_{aa}| = 0 \quad . \quad . \quad . \quad (3)$$

for its largest root λ_1, which in this case is equal to the maximum reliability r_m. The weights u are given by any row of the matrix $\mathrm{adj}(R_{aa} - \lambda_1 R_{aa})$.

Use of equation (3) avoids the awkward triple product $R_{aa}R_{aa}^{-1}R_{aa}$ in equation (1) and so shortens the computation considerably. The method I have outlined can be proved to lead to the same results for r_m and u as Thomson's method.

Densest Packing of Equal Spheres

THE two equally dense cubic and hexagonal packings discovered by Barlow[1] in 1883 are now widely known. But it does not appear to be equally well known that there are also four homogeneous mixtures of these; so that we have in all no less than six homogeneous arrangements all possessing maximum density. Barlow himself was aware of the possibility of admixture[2], but so far as I know the matter has never been fully expounded, and in view of the increasing practical importance of the subject it is perhaps well that it should be.

When equal plastic spheres are arranged cubically and then uniformly compressed, they become rhombic dodecahedra. Spheres arranged hexagonally become in like circumstances trapezo-rhombic dodecahedra.

Take, therefore, quantities of rhombic dodecahedra (R) and trapezorhombic dodecahedra (T) to represent the *Wirkungsbereich* of sphere-centres in a homogeneous structure. We note that there cannot be more than two successive layers ($2R$) or ($2T$) in a homogeneous mixture; for when there are three, the polyhedra in the middle layer are completely surrounded, and therefore *all* polyhedra in additional layers must be surrounded in the same way. In other words, if three successive layers are all R (or T), then all layers in the structure must be R (or T), and the arrangement is Barlow's cubic (or hexagonal).

It remains only to determine the possible arrangements of polyhedra in which not more than two successive layers are of the same kind, and it is found upon trial that there are four, and no more.

Starting with all layers R, substitute a single T layer; we then have:

Homogeneous mixture No. 1. $T,R,R,T,R,R,\ldots$
" " No. 2. $R,T,R,T,R,T,\ldots$

Substituting two successive T layers, we have:

Homogeneous mixture No. 3. $R,R,T,T,R,R,T,T,\ldots$
" " No. 4. $R,T,T,R,T,T,R,T,T,\ldots$

where successive letters in a row indicate the nature of successive vertical layers in the structure.

In No. 1 the seventh layer overlies and has the same orientation as the first; in No. 2 the fifth; in No. 3 the thirteenth; and in No. 4 the tenth.

Richmondite, a Discredited Mineral Species

EIGHTY years ago William Skey[1,2] analysed and described a mineral from Richmond Hill in northwest Nelson, New Zealand, naming it 'richmondite'. His analysis of this material, after deducting 15·4 per cent for siliceous gangue and antimony oxychloride, is as follows: PbS 36·12, Sb_2S_3 22·20, Cu_2S 19·31, FeS 13·59, ZnS 5·87, Ag_2S 2·39, MnS 0·52, Bi_2S_3 traces: total 100. From this analysis Skey calculated the formula $Sb_2S_3.6RS$ (where R = Pb, Cu, Fe, Ag, Zn), and it was his belief that the mineral, though quite distinct from tetrahedrite, was related thereto.

I have prepared polished surfaces from a number of specimens labelled 'Richmondite' that exhibit the properties described by Skey, and I find that not one of these specimens is homogeneous. Instead, the following minerals were found in each specimen: argentian tetrahedrite, galena, sphalerite, chalcopyrite, pyrite, and possibly stromeyerite; these minerals are placed in order of abundance, although in some instances sphalerite is more plentiful than galena. The galena shows no traces of inclusions of argentite, and chemical tests on powder obtained by scratching the surface of the grains did not suggest the presence of any silver in the galena. The tetrahedrite, on the other hand, contains much silver, but unfortunately the powder was not sufficiently pure to warrant a quantitative determination.

Within the tetrahedrite, however, are to be seen occasional, very small inclusions of grey colour that are distinctly anisotropic. The mineral is soft, has a blackish streak, and the standard etch tests give the following reactions: nitric acid, stains iridescent; hydrochloric acid, negative; potassium cyanide, quickly stains black; ferric chloride, stains iridescent; potassium hydroxide, negative; mercuric chloride, stains slowly. These characters are closely comparable to, and suggest, stromeyerite[3].

Therefore, in view of the lack of homogeneity in the material known as 'richmondite', the latter cannot be considered a true mineral species, and the name should be abandoned.

Relative Directions of the Electric and Magnetic Vectors in Electromagnetic Waves *in vacuo*

IN my recent communication in *Nature*[1] on the relative directions of the electric and magnetic vectors in electromagnetic waves *in vacuo*, the words "Even if the electric and the magnetic vector were orthogonal to its respective curl (which is *not always* the case), it would only follow from the Maxwell equations" should be substituted for "It follows from the Maxwell equations". The original version implied that in the electromagnetic waves *in vacuo* the electric and the magnetic vector is *always* perpendicular to its respective curl, which is not true, and, apart from this, was superfluous in the main argument.

This correction is the sequel of letters which I have received from Prof. Erwin Schrödinger and from Dr. K. M. Guggenheimer, who wrote to me quite independently about ten days later. To both of them I wish to acknowledge my indebtedness.

LEAD SULPHIDE PHOTOCONDUCTIVE CELLS

By L. SOSNOWSKI, J. STARKIEWICZ
AND
O. SIMPSON
Admiralty Research Laboratory, Teddington, Middlesex

Manufacture

IN view of the interest being shown in the applications of lead sulphide cells[1,2] and in the photoelectric properties of the sensitive material[3], it is desirable to give a brief account of the method of manufacture of these cells, and to specify the conditions which govern the appearance of high photosensitivity. The method of manufacture described here has been developed during the last two years at the Admiralty Research Laboratory.

There are three main processes involved:

(i) About 4 mgm. of lead sulphide, enclosed in the 'Pyrex' cell blank, is heated in oxygen (pressure about 0·2 mm. mercury) at 550°–600° C. The sulphur dioxide evolved is removed. This process results in the conversion of some of the lead sulphide into lead oxide (PbO); the amount of oxide is not critical (5–40 per cent).

(ii) This material is used to form a layer 1–2 microns in thickness by evaporation on to a glass surface bearing graphite electrodes. The evaporation is made in oxygen (pressure about 0·2 mm. mercury).

(iii) The layer is then heated in oxygen (pressure as before) up to 450° C. This treatment is the most critical and is controlled by observing the variations in conductivity of the layer. The conductivity, which initially increases with the temperature, afterwards decreases and goes through a minimum; it is necessary to continue the heating until this minimum has been passed and a rapid increase of conductivity occurs (at about 400° C.). The cell is then cooled rapidly to room temperature in oxygen and evacuated. In some cases the sensitivity may be improved by a short heating *in vacuo* to 250° C.

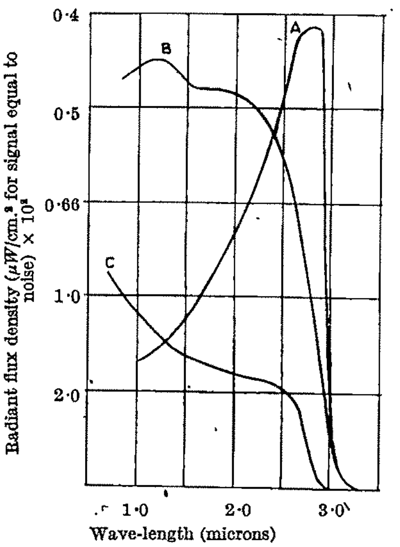

Fig. 1. SPECTRAL SENSITIVITY OF TYPICAL LEAD SULPHIDE CELLS. RADIATION INTERRUPTION, 800 C./SEC.; 30-CYCLE BAND-WIDTH

Cells prepared in this way have retained sensitivity to date. They have a response time of the order of 0·1 millisec. and exhibit linear response to weak illumination. Curve *A*, Fig. 1, shows the spectral response of a typical cell. If the concentration of lead oxide is high, the spectral response is altered, and a secondary peak appears at about 1 micron. The relative intensity of this peak increases with the amount of lead oxide, the maximum sensitivity being shifted into the visible region. Curves *B* and *C* show the response of two cells with progressively increased proportions of lead oxide.

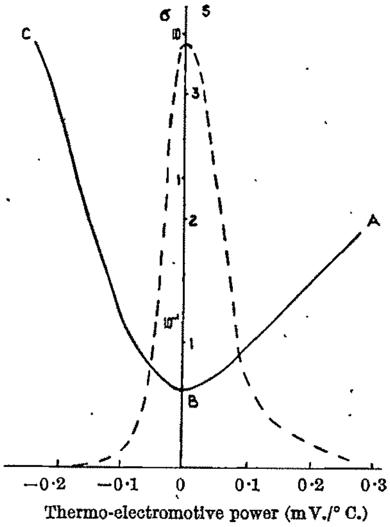

Fig. 2. VARIATION OF CONDUCTIVITY (FULL LINE) AND SENSITIVITY (BROKEN LINE) WITH THERMO-ELECTRIC POWER

Our measurements of Hall coefficient and thermoelectric power have established that layers may be predominantly excess conductors or defect conductors, associated respectively with excess of lead or oxygen impurity centres. Fig. 2 shows the relationship between the thermal E.M.F., the conductivity, and the photosensitivity of a sensitized layer which was initially a defect conductor (point *A*). The graph was obtained by applying successive heatings to 250° C. *in vacuo*. It was independently proved that this treatment effects the removal of excess oxygen but does not create any lead impurities. Since the thermal E.M.F. changes sign from positive to negative (point *B*) while the conductivity rises rapidly (from *B* to *C*), it is necessary to assume that there are lead centres in the layer which must have been present even when excess of oxygen produced a resultant defect conductivity. This lead is formed in dynamic equilibrium with lead sulphide and various oxidation products during oxidation at temperatures above 400° C. Thus stage (iii) in the preparation causes changes in the concentrations of both lead and oxygen impurity centres. The variations in conductivity which occur during this treatment may be fully explained in terms of these changes.

The maximum sensitivity is assured when both kinds of impurity centres are present in sufficient quantity, and with relative concentration such that the minimum conductivity and zero thermoelectric power are obtained. No sensitivity has ever been obtained with only one type of impurity centre present.

Theory of the Photoeffects

We have already discussed[4] briefly our experimental work on the photoconductive and photovoltaic effects in lead sulphide.

The critical experimental results that must be taken into account are: (i) that sensitive layers can be produced with rectifying and photovoltaic properties; and (ii) that photoconductivity is necessarily associated with the simultaneous presence of lead and oxygen impurity centres.

It seems unlikely that photosensitivity could be associated with uniform distribution of impurity centres of two kinds. We therefore postulate the existence of regions in which there is an excess of lead, and regions where oxygen impurity centres are predominant. It is natural to attribute these inhomogeneities to differences in size and chemical composition (lead oxide content) of the individual microcrystals comprising the layer. Purely random variations might be a contributory factor.

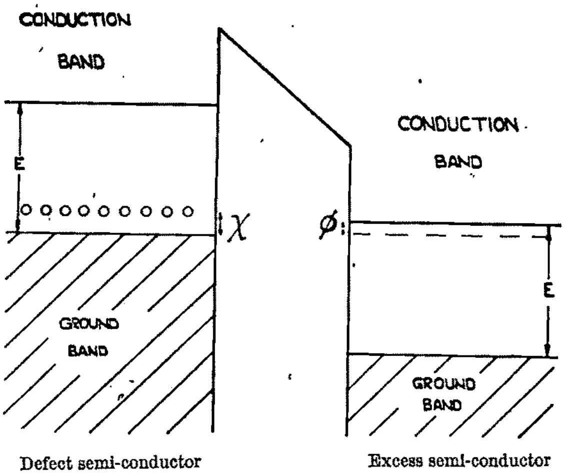

Fig. 3. ENERGY-LEVEL MODEL

○ ○ ○, oxygen impurity centres.
- - - -, lead „ „

We now discuss the boundary between two regions, one containing excess of oxygen and the other excess of lead. In equilibrium, the density of electrons in any energy state must be identical on either side of the boundary. There will be, therefore, a flow of electrons across the boundary from the side of excess lead, resulting in the formation of a space charge. A simplified model of the energy-level scheme in equilibrium is shown in Fig. 3. The relative displacement of the levels will be dependent on temperature, but the dependence can be neglected in the case considered (number of impurity centres much greater than the number of intrinsic electrons at room temperature). Our observations on the behaviour of lead sulphide containing one kind of impurity only indicate that φ and χ are small compared with kT. A concentration of impurity centres of about 10^{19} per c.c. on either side of the boundary may represent the typical case. The displacement E between ground-level and conduction bands is approximately 0·5 eV. as deduced from the long-wave limit of the main absorption spectrum of lead sulphide.

Any boundary of the type shown in Fig. 3 will have rectifying properties. The electron flow can be due to the passage of electrons between the conduction bands, between ground-band and conduction-band, and between ground-bands, the relative contribution depending on applied voltage and barrier characteristics. For low values of applied voltage the first process predominates, giving a direction of easy flow from right to left. As the concentration of electrons in the conduction band on the left is very small (about 10^{11} per c.c.), the resistance of the barrier is high compared with the resistance of the semi-conducting material.

If the absorption of infra-red radiation ejects electrons from the ground-band or oxygen impurity centres into the conduction band, the concentration of electrons which are able to cross the barrier will be greatly increased, with corresponding reduction of resistance. Even when there is no applied potential, photo-electrons will still diffuse across the barrier. The probability of return is negligible, since once the electrons have diffused across to the right of the barrier, the loss of energy due to collision will prevent return. In consequence a photo-electromotive force will be generated.

We believe that this mechanism is responsible for the photovoltaic effect in lead sulphide (*loc. cit.*). More direct evidence has since been obtained by preparing a layer one half of which contained excess lead and the other excess oxygen, as was verified by measurements of thermal E.M.F. This layer contained effectively only one barrier of the type described, and showed the photovoltaic effect with the direction predicted by the theory.

If a layer contains many barriers distributed at random, the photovoltaic and rectifying effects will not be observable. However, the existence of the barriers will be the main factor controlling the resultant conductivity of the whole layer. Illumination will ease the flow of electrons, which accounts for the photoconductivity.

Between the barriers the current may be carried either by electrons or by positive holes, depending upon the type of impurity predominant in the region. Across the barriers the main contribution to the current is due to electrons, and there is some evidence that the Hall coefficient becomes negative (or less positive) on illumination.

According to this model, the spectral characteristics should be similar for the photoconductive and photovoltaic effects; furthermore, it should be determined mainly by the energy difference E between the top of the ground-level and the bottom of the upper conduction band, the actual position of the impurity-levels being of secondary importance. The first of these points has been verified experimentally, and support is given to the second by the appearance of a short wave-length peak when the concentration of lead oxide is high.

The above discussion has dealt only with the main aspects. A quantitative treatment based on the above model has given results in general agreement with experiment for features such as sensitivity, rectifying effect and time of response.

We have to acknowledge the assistance of Messrs. J. Beattie and D. Phillips in supplying the data on sensitivity and spectral response.

A complete report on the preparation and properties of lead sulphide cells and on the theory of the photoelectric effects is in the course of preparation.

PLOT-SIZE IN YIELD SURVEYS

By Dr. V. G. PANSE
Institute of Plant Industry, Indore

RECENT communications by Sukhatme[1,2] and Mahalanobis[3] have established the conclusion that sample plots of a small size (25 sq. ft. or less according to Mahalanobis) give biased estimates of yield in sample surveys ; but whereas Sukhatme has shown the bias to persist even with a plot-size of 118 sq. ft., Mahalanobis has expressed the view that it becomes practically negligible for plots of size larger than 40–50 sq. ft. Their results relate to crops grown unevenly by broadcasting the seed or sowing it in irregular lines. I have studied the problem of plot-size in yield surveys on cotton, which is sown by a drill in evenly spaced rows in Central India. The results[4] are summarized here, as they provide for the first time information on this question applicable to drill-sown crops.

Plots of three sizes, 1/20, 1/200 and 1/2,000 acre, were compared. In crops sown in uniformly spaced rows, plot-size is defined by a specified length of a given number of contiguous rows. The plots in the present experiment were marked according to this definition, and since the actual plot-sizes differed slightly from the standard size owing to small variations in row spacing, the plot-yields were reduced to the standard size before analysis. Two plots of each size or six plots in all were laid down at random locations in the field. The experiment was done in twenty-six fields at Indore and in an equal number of fields at Government farms in the Central Provinces. In addition to the yields of the plots, yields of whole fields were accurately measured at the Government farms ; but this was unfortunately not possible at Indore. Average yields of seed cotton per acre estimated from the three plot-sizes were :

	Yield (lb. per acre)	
Plot size	Indore	Central Provinces
120 acre	195·7	322·2
1/200 „	197·0	354·9
1/2,000 „	221·3	421·8

There was a gradual increase in yield per acre as the plot-size was decreased in the Central Provinces experiment. At Indore also the yield from the smallest plot was larger than the other two. A comparison between different plot-sizes did not, however, reveal significant differences in yield, though the excess of yield estimated from 1/2,000-acre plots over 1/20-acre plots in the Central Provinces was almost twice its standard error. The comparison of yields estimated from sample plots with the yield obtained by harvesting the whole fields in the Central Provinces proved more conclusive, as shown below :

Comparison of plots with whole fields	Difference in yield (lb. per acre)
1/20 acre plot	26·7 ± 26·5
1/200 „ „	59·4 ± 28·1
1/2,000 „ „	126·3 ± 57·6

The yield estimated from 1/20-acre plots agreed quite well with the yield for the whole field, as the difference between the two was no more than its standard error ; but the excess of the yield estimated from the other two plots over the yield from the whole field was greater than twice its standard error and clearly significant. With 1/2,000-acre plots, the over-estimation was as high as 42·7 per cent of true yield.

Thus, not only did the smallest plot size, 1/2,000-acre or 22 sq. ft., give highly biased results, but also there was an indication of bias also with the plot size of 1/200 acre or 218 sq. ft. in the Central Provinces experiment. The latter result would seem to show that even plots of 200 sq. ft. cannot always be relied upon to give unbiased estimates of yield. The second conclusion from this experiment is that although small plots, such as those used by English and American workers for sampling drill-sown crops, may not be open to serious objection for comparative purposes, the possibility that yield estimates derived from such plots are seriously biased needs attention.

FUTURE OF PAINT*

MODERN developments in plastic materials have forced the paint industry to concern itself with an ever-increasing number of film-forming substances—synthetic rubbers, resins and oils ; and researches on pigments have not lagged behind. The electron microscope reveals the shape of particles too small for optical resolution. Pigment particles had been assumed to be spherical ; it transpires, however, that of the pigments commonly used only carbon particles have this shape. The shape of carbon particles is independent of the material from which the pigment is prepared. Carbon smoke is different from other inorganic smokes, which, with the exception of aluminium oxide, yield crystalline particles, and the reason for this difference has not been fully explained. The carbon pigments have another interesting property, namely, that of forming chains, like beads on a string. Such an arrangement may be due to electrostatic charges ; but whatever the cause, the condition probably accounts for the high electrical conductivity of carbon-pigmented paint.

Study of the forces which exist at the interface between pigment and medium has shown that they develop the plasticity of the paint on which its working properties depend, and later determine the manner of film formation and structure. Usually they develop quickly and promote dispersion of the pigment. There are cases, however, which can be regarded as dramatic exceptions ; for example, sparks up to half an inch long accompany the attempted dispersion of titanium dioxide by grinding in tricresyl phosphate under electrically insulated conditions, whereas in the presence of a trace of surface-active material (oleic acid) dispersion proceeds normally without the visible release of energy. When paint fails, that is, cracks and exfoliates, the shrinkage forces overcome the combined forces of cohesion (pigment/medium) and adhesion (film/support). When adhesion is good, the development of other paint defects is delayed.

Research into these matters has been conducted by the optical examination of paint sections. In order to use the electron microscope for examination of paint films it is necessary to prepare a replica of the paint surface on a material sufficiently thin to transmit the electron beam. This is done by taking a negative impression of the surface structure of the paint by the simple process of spreading methyl

* Substance of the Friday Evening Discourse entitled "Whither Paint ?" delivered by Dr. L. A. Jordan at the Royal Institution on March 7.

cellulose solution upon it. When dry, this is stripped off and a positive impression is prepared by allowing evaporated silica to condense on the surface in a vacuum; after removal of the methyl cellulose, the siliceous replica is ready for examination. By this technique it is possible to observe the disruption of a paint surface in its early stages—even after a few hours of exposure to accelerated ageing and weathering in the laboratory.

Red lead is generally still the first choice as a rust-inhibitive pigment in spite of many interesting developments in the study of corrosion of iron. Its disadvantages are its density and scarcity. Lead cyanamide is of lighter colour and somewhat lower density, and is being developed as a substitute for red lead.

During the War many special-purpose paints were used; for example, luminous paints, conducting paints and paints sensitive to changes of humidity and temperature. The active agent in almost every case was the pigment, which itself acted as the indicator of the changes, usually by a variation of colour. An interesting feature of luminous materials is that the energy stored as a consequence of activation is quickly released when the paint is heated. This energy can also be released by increasing the internal friction. Thus, when a luminous paint film is bent inwards there is a release of energy as a flash of light. When the bend is outward (internal friction not so great) the energy released is much smaller. The bending of a paint film also modifies its electrical conductivity. This effect is more readily observed with a carbon pigment, the electrical conductivity of which is presumed to be due to the chains of carbon particles which it contains. Bending inwards (compression) decreases the electrical resistance by bringing the carbon particles nearer together: bending outwards has the opposite effect. Graphite is lamellar in form, and its low resistance is ascribed to chains of overlapping plates lying within the paint film. But not all lamellar pigments form a conducting path, even if composed of a material of low resistance. The outstanding example is aluminium paint, which gives a bright metallic film but which, however, is non-conducting. The plates are insulated from each other by a surface film of polishing agent, usually a stearate, and a tightly held oxide layer. The polishing agent is responsible for the floating and leafing of the particles within the paint film, whence arises its lustre. A conducting paint film can be obtained from copper powder only when the surfaces are chemically clean and are maintained in the reduced condition.

The use of paint as a medium for employing chemical compounds that undergo colour changes at certain critical temperatures has met with a certain amount of success, and organic dyestuffs giving a colour change that is irreversible with temperature can be used to record temperatures inside machinery where the use of thermometers or thermo-couples would be impracticable. A particular example of this application is in recording whether or not a bearing has been overheating. Compounds with reversible colour changes have also been of use, and the double iodide of copper and mercury, which changes from red to black as the temperature rises above 90° C. and gives the reverse colour change on cooling, served, during the War, as an indicator on the distillation apparatus of lifeboats. It was easier for men in distress to note a change of colour than to have to read a thermometer.

In recent years most old-established industries have attempted to introduce scientific tests that would be independent of the human element, and the paint industry is no exception. A difficulty arises, however, in the recording of such qualities of a painted surface as 'gloss' and 'lustre', which are normally judged by the human eye. Experience of instruments devised for such measurement has shown that these properties are not measurable in the same way as mass and length, but that they have a subjective element which, so far, has defied instrumental interpretation. This brings us to the fundamental characteristic, the measurement of colour, which provides its own psychological problem. Accurate tricolorimetric or spectrophotometric measurement permits recording of primary colour and brightness values which are now accepted as the ultimate standards against which the colour patterns or secondary standards may be checked at intervals. The difficulty arises in deciding what can be taken as an acceptable match to a standard colour with permissible tolerances. The methods of colorimetry have reached a high degree of precision, but they only deal with colour objectively; they measure stimuli and not the sensation of colour. What is wanted is a relationship between stimulus and the corresponding changes in mental colour-sensation, and if such a relationship could be established it would no doubt contribute to the solution of one of the outstanding problems of the paint industry, namely, control of the drift of patterns away from their original colour, even when they are kept in the dark.

As to the future, it is certain that new products will produce new and improved paints. The corrosion problem may be expected to diminish with the use of less corrodible materials; but whatever happens in this respect there will always be the desire to provide good appearance and pleasing colours.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, June 16

UNIVERSITY COLLEGE, LONDON (at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Prof. Kapp: "The Presentation of Technical Information", Second Series, 3: "The Part Played by Logic in Presentation".*

Tuesday, June 17

RESEARCH DEFENCE SOCIETY (at the Royal Society of Tropical Medicine and Hygiene, Manson House, 26 Portland Place, London, W.1), at 3.15 p.m.—Annual General Meeting. Prof. G. H. Wooldridge: "What Animals Owe to Experimental Research" (Sixteenth Stephen Paget Memorial Lecture).

MEDICAL RESEARCH COUNCIL (at the Royal Institution, 21 Albemarle Street, London, W.1), at 5 p.m.—Dr. J. G. Hamilton (Radiation Laboratory, Berkeley, Calif.): "Applications of Radio-active Isotopes in Medicine".*

Wednesday, June 18

GEOLOGICAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Mr. C. E. N. Bromehead: "A Geological Museum of the Early Seventeenth Century".

ROYAL METEOROLOGICAL SOCIETY (at 49 Cromwell Road, London, S.W.7), at 5 p.m.—Sir Gilbert T. Walker, F.R.S.: "Arctic Conditions and World Weather"; Mr. S. Duvdevani: "An Optical Method of Dew Estimation".

Thursday, June 19

CHADWICK PUBLIC LECTURE (at the Chelsea Physic Garden, Swan Walk, London, S.W.3), at 4 p.m.—Prof. W. H. Pearsall, F.R.S.: "Water Supply and Freshwater Biology".*

ROYAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Mr. B. M. Cwilong: "Sublimation in a Wilson Chamber"; Sir Lawrence Bragg, F.R.S., and Mr. J. F. Nye: "A Dynamical Model of a Crystal Structure".

Institution of Mining and Metallurgy (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. G. A. Schnellmann and Mr. J. D. Willson: "Lead-Zinc Mineralization in North Derbyshire"; Mr. E. W. O. Dawson: "War-time Treatment of the Lead-Zinc Dumps situated at Nenthead, Cumberland".

London Mathematical Society (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Prof. J. H. C. Whitehead, F.R.S.: "Maps of 3-Dimensional Spheres on 2-Dimensional Spheres".

Royal Society of Tropical Medicine and Hygiene (at Manson House, 26 Portland Place, London, W.1), at 8 p.m.—Annual General Meeting; Brigadier Sydney Smith: "Prisoner of War Camps in the Middle East".

Friday, June 20

Institute of Physics, Industrial Spectroscopic Group (joint meeting with the Scottish Branch of the Institute of Physics, and the Spectrographic Discussion Group, Glasgow, in the University, Glasgow), at 9.30 a.m.—Dr. R. L. Mitchell and Dr. R. O. Scott: "The Spectrographic Analysis of Non-Conducting Powders in the Carbon Arc"; at 2 p.m.—Dr. E. W. H. Selwyn: "The Photographic Aspect of Spectroscopy"; at 3.30 p.m.—Mr. G. P. Mitchell and Mr. P. Popper: "The Use of the Multiplier in Emission Spectroscopy".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer in Mathematics, and a Lecturer in Chemistry—The Principal, Central Technical College, Suffolk Street, Birmingham 1 (June 21).

Lecturer in Mathematics—The Registrar, Technical College, Sunderland (June 21).

Senior Assistant in Mechanical Engineering, a Senior Assistant in Metallurgy, a Responsible Lecturer in Structural Engineering, a Lecturer in General Chemistry, and a Lecturer in Mechanical Engineering, at the Constantine Technical College—The Director of Education, Education Offices, Middlesbrough (June 21).

Lecturer in Physics—The Clerk to the Governors, Royal Technical College, Peel Park, Salford 5 (June 21).

Lecturer in Mining and Engineering Subjects—The Principal, Technical Institute, Clowne, Chesterfield (June 21).

Lecturer in Applied Mathematics at the Ipswich School of Technology—The Chief Education Officer, 17 Tower Street, Ipswich (June 21).

Lecturer in the Department of Electrical Engineering, and a Lecturer in Biology and Horticulture, at the City Technical College, Liverpool—The Director of Education, 14 Sir Thomas Street, Liverpool 1 (June 21).

Graduate Lecturer with good qualifications in Physics, at the Oldham Municipal Technical College—The Director of Education, Education Offices, Oldham (June 21).

Assistant Lecturer in Chemistry (Physical)—The Registrar, The University Reading (June 23).

Lecturer in the Department of Physiology, and Lecturers (2) in the Department of Agriculture (with special training, experience, and knowledge of animal and dairy husbandry, and of crop and grassland husbandry)—The Secretary, The University, Aberdeen (June 26).

Lecturer in the Department of Natural History, and a Lecturer in Soil Science—The Secretary, The University, Aberdeen (June 28).

Assistant Lecturers (2) in the Department of Engineering—The Registrar, University College, Singleton Park, Swansea (June 28).

Experimental Officer to assist in metabolism studies in animal nutrition and routine analysis, an Experimental Officer with considerable knowledge of micro-chemical and microbiological methods, and an Experimental Officer with experience in routine analysis of foodstuffs, blood and excreta—The Secretary, Rowett Research Institute, Bucksburn, Aberdeenshire (June 28).

Lecturer in Biology, and a Lecturer in Chemistry—The Clerk to the Governors, Woolwich Polytechnic, Woolwich, London, S.E.18 (June 28).

Lecturer in the Mathematics Department—The Principal, Heriot-Watt College, Edinburgh (June 30).

Speech Therapist—The Director of Education, City Education Office, Northumberland Road, Newcastle-upon-Tyne 1 (June 30).

Lecturer in Crop Husbandry and Farm Machinery, and an Assistant Lecturer in Biochemistry—The Registrar, The University, Leeds 2 (June 30).

Senior Lecturer, a Lecturer or Assistant Lecturer, and an Assistant Lecturer or Demonstrator, in the Department of Glass Technology—The Registrar, The University, Sheffield (July 1).

Assistant Lecturer in Chemistry, an Assistant Lecturer in Geography, a Lecturer in Geology, an Assistant Lecturer in Mathematics, and a Statistician (Lecturer's grade) attached to the Department of Mathematics—The Registrar, University College, Hull (July 2).

Deputy to the City Analyst—The Medical Officer of Health, Public Health Department, Leeds, endorsed 'Deputy City Analyst' (July 5).

Technical Officer—The Secretary, Research Association of British Rubber Manufacturers, 105 Lansdowne Road, Croydon (July 5).

Research Assistant in Agricultural Economics—The Professor of Agricultural Economics, The University, 7 Redlands Road, Reading (July 15).

Professor of Physics, and a Professor of Chemistry—The Registrar, Indian Association for the Cultivation of Science, 210 Bowbazar Street, Calcutta, India (July 30).

Principal of Victoria University College, Wellington, New Zealand—The Secretary, Universities Bureau of the British Empire, 8 Park Street, London, W.1 (July 31).

Chair of Pharmacology—The Registrar, The University, Sydney, Australia (July 31).

Professor of Physics—The Registrar, The University, Allahabad, U.P., India (August 31).

University Graduates and Qualified Teachers for short-service commissions of 3, 4 or 5 years in the Education Branch of the Royal Navy—The Director, Education Department, Admiralty, London, S.W.1.

Experimental Officer in the Spectrographic Department—The Secretary, Macaulay Institute for Soil Research, Craigiebuckler, Aberdeen.

Lecturer in Geography—The Principal and Clerk to the Governing Body, Wigan and District Mining and Technical College, Wigan.

Soil Technologist by the Government of Iraq—The Crown Agents for the Colonies, 4 Millbank, London, S.W.1, quoting M.N.14628.

Physicists for research work in thermionic emission and high vacuum work, electronics, electrical and magnetic instruments, and industrial process control—The Director and Secretary, British Scientific Instrument Research Association, 26 Russell Square, London, W.C.1.

Laboratory Technician (Grade II) for Chemistry Department—The Secretary, Medical School, Guy's Hospital, London Bridge, London, S.E.1.

Technical Abstractor—The Director, Motor Industry Research Association, Great West Road, Brentford, Middx.

Lecturer in Radiology in the Department of Anatomy, and an Assistant Lecturer in Embryology—The Secretary, University College, Gower Street, London, W.C.1.

Registrar—The Registrar, University College, Exeter.

Senior Lecturers in (*a*) Aeronautics, (*b*) Applied Mechanics, (*c*) Chemical Engineering, and Lecturers (Grade I) in (*a*) Civil Engineering, (*b*) Mechanical Engineering, (*c*) Applied Mechanics—The Secretary, Royal Technical College, Glasgow.

Graduate in Engineering, with industrial experience, for work up to Higher National Certificate standard in Mechanical Engineering—The Principal, Technical College, Kendrick Hall, Stroud, Glos.

Lecturer in Chemistry, and a Lecturer in Mathematics—The Principal, Technical College, Kingston Hall Road, Kingston-upon-Thames, Surrey.

Lecturer in Mathematics, and a Lecturer in Zoology—The Principal, Guildford County Technical College, Stoke Park, Guildford, Surrey.

CONTROL OF ATOMIC ENERGY

ALTHOUGH freely quoted, the first report of the Atomic Energy Commission to the Security Council of the United Nations, dated December 31, 1946 (see *Nature*, May 3, p. 616), does not yet appear to have been generally available in Great Britain. It is the more important, therefore, that the situation should be repeatedly and publicly discussed, and that the facts and their implications should be made known alike by such means as *Current Affairs*, the December 28, 1946, issue of which was devoted almost entirely to a review by Peter Wright entitled "The Future and the Atom Bomb", and by the series of broadcast talks arranged by the British Broadcasting Corporation in the spring and published in *The Listener* of March 13. Such popular expositions are important adjuvants to the efforts of the Atomic Scientists Association and the survey of the Committee on Science and its Social Relations of the International Council of Scientific Unions, especially when, as in *Current Affairs*, they are documented for further reading.

For that reason the debate in the House of Lords on April 30 on a motion by the Archbishop of York deserves more than passing notice; it was also notable as the first occasion for an authoritative public discussion in the Houses of Parliament on the present political deadlock regarding the atomic bomb. The statement made on June 11 on behalf of the Soviet Government by Mr. Gromyko, although it suggests movement towards the views of the remainder of the Atomic Energy Commission, is still not clear on the subject of the proposed international authority and its autonomy.

The main theme of the Archbishop of York's speech was the urgency of the situation; but there was a striking similarity in the trend of his thought to that in the latest report of the President of the Carnegie Institution of Washington. Commenting on the bearing on the Institution's work of this scientific revolution in warfare which has given the application of science a central place in national security, Dr. Vannevar Bush recognizes that there is an important time factor, and that the principal question is whether there must be another demonstration of the power of applied science to destroy before mankind realizes that a new approach towards international functioning is demanded; but he also urges that the race between the power of weapons and the power of understanding is not altogether one-sided. Dr. Bush points out that the application of science has done more than create a destructive power which has made a world organisation essential: it has also provided the means of swift communication and transport which make real unity possible, and progress in medicine has done much to make possible that healthy outlook on life which is necessary for great movements of collaboration. The Archbishop of York, while not regarding as necessarily fatal the Russian insistence on a prior convention outlawing the use of the atomic bomb, provided that agreement could be reached as to the destruction of bombs not handed over to the authority as soon as that authority is effectively established, believes that the limitation on inspection is a most serious difficulty, and that the dangers are very real unless an international authority is speedily brought into existence. Nor can there be any effective authority, in his opinion, unless it is able to override national sovereignty at least to some extent. The first and most practical step towards the abolition of war is the creation of an authority with real power of control and inspection.

Here Dr. Garbett took up a position which men of science have consistently occupied from the start, and he went on to urge in words reminiscent of General Smuts' presidential address to the British Association at its centenary meeting, that the position has arisen because man's immense advances in scientific knowledge have not been accompanied by corresponding advances in moral stature. Lord Cherwell, who followed, at once agreed with what Dr. Garbett said both on this point and especially on the necessity of the nations agreeing to transfer some part of their sovereign independence to an authority able to administer the law and enforce order; his main disagreement with the Archbishop being on the latter's comments on the Bikini experiments. Lord Cherwell made it clear that he rests his own hopes chiefly on proceeding along the lines outlined in the American plan, which he considers is realistic, detailed and carefully thought out. While nations cling to the inviolability of national sovereignty, there is, he believes, little hope of achieving any useful result in the negotiations. Without some authority to enforce the law, and standing above all the members of the community, the best laws in the world are of little avail.

It cannot be said that in this debate there was any clear indication as to how the deadlock created by the Russian attitude can be resolved. Earl Russell insisted that the fundamental question is not of Russian interests, American interests or British interests; but of human interests. Ultimately, it is a question of the abolition of war, and if it is possible that the attempt to isolate and to deal separately with the atomic problem is a mistake, it may none the less be valuable if we can demonstrate, even in a limited field among the nations willing to participate, the practicability of an international authority such as the Lilienthal Report has outlined. That was Lord Lindsay's contention; and Viscount Addison, reviewing the position for the Government, could say but little more than that the technical committee has reported unanimously to the Atomic Energy Commission that it is possible to extend among all nations the exchange of basic scientific information on atomic energy for peaceful ends; to control atomic energy to the extent necessary to ensure its use only for peaceful purposes; to ensure the elimination from national armaments of atomic weapons; to provide safeguards by way of inspection and other means to protect complying States against the hazards of violations and evasions.

These, as Viscount Addison said, are four vital conclusions, but they represent only a small step forward; and although the Atomic Energy Commission has now been asked by the Security Council to resume its work, it would seem that the main hope of progress lies in the formation of a public opinion—in Great Britain and in other countries—which fully understands what is involved and is determined that the price of peace shall be paid, no matter what sacrifice of national sovereignty is required. What needs to be grasped as firmly and widely as possible is that technical opinion is agreed as to the feasibility of control, and that such control means some surrender of national sovereignty. It is the task, then, of those who have understood this issue to bring home to their fellow citizens that this is now a matter of human rights, and of one of those four human freedoms with which President Roosevelt touched the imagination of the freedom-loving peoples. Here, as in the matter of an international police force, it must be made clear to all where the threat to human rights arises, and exactly where progress is being obstructed. Nothing has yet emerged from the debates of the last eighteen months which suggests that any wide deviation is likely from the principles outlined in the Baruch plan. While men of science, through the Atomic Scientists' Association and in other ways, continue to address themselves to this task of educating world opinion, they should equally continue the detailed discussion of the plan on which so much time has already been spent; they should seek to formulate an international document in which the exact nature and mode of operation of an international authority are clearly stated, and work to secure its demonstration in practice in as wide a field as is possible.

ADVANCES IN BIOCHEMISTRY

Advances in Enzymology and Related Subjects of Biochemistry

Edited by F. F. Nord. Vol. 6. Pp. x+563. (New York: Interscience Publishers, Inc., 1946.) 6.50 dollars.

THE articles contained in "Advances in Enzymology", like those in the "Annual Reviews of Biochemistry", are becoming increasingly indispensable to research workers, teachers, and writers of text-books on biochemistry. Reviews of the progress made in the various branches of this rapidly expanding science have become essential to all who wish to keep abreast of the literature. The writers of these reviews have great responsibilities, for their readers look to them not only for an authoritative exposition of recent advances but also for an unbiased judgment on the new developments and for full acknowledgment of the work of all research workers who have contributed to the advances. This duty of fair presentation and appraisal is usually faithfully carried out. This seems clearly to be the case, so far as the writer is able to judge, with the articles in the volume of "Advances in Enzymology" under review.

Dr. E. F. Gale writes a very useful and timely article on the subject of bacterial amino-acid decarboxylases, a subject to which he himself has made very important contributions. These enzymes are responsible for the breakdown, in bacteria, of amino-acids to amines, and Gale has shown that they are formed within bacterial cells in response to certain well-defined conditions of growth. The enzymes have been obtained and studied in cell-free condition. Dr. Gale's article describes in detail the conditions necessary for the formation of the amino-acid decarboxylases, the manner in which enzyme production is affected by the amino-acid in presence of which the bacteria are grown and the importance for the process of decarboxylation of a coenzyme, which the work of Bellamy and Gunsalus, and of Snell, has shown to be pyridoxal phosphate.

Reviews of the biochemistry of amylases are written by R. H. Hopkins and by W. F. Geddes. It is now more than a hundred years since Payen and Persoz (in 1833) applied the name diastase to the starch-splitting enzymes of barley malt; this name persisted until recent times, but the term amylase is now preferred. Although there is no general agreement, according to Geddes, on the number of enzymes which are involved in starch hydrolytic breakdown, two main types are required, namely, β-amylase, the so-called saccharogenic amylase, and α-amylase, the dextrinogenic and liquefying amylase. Hopkins' article deals with the general features of α- and β-amylases, describes the influence of ions on these enzymes and discusses their stabilities and kinetics. He considers that α-amylase "is the fundamental amylase with its high affinity for starch and its power of relatively rapid dextrinization" and that β-amylase "fulfils the role of an accessory which speeds up and completes the process of saccharification". Geddes' extensive article not only describes the occurrence and properties of the amylases and other starch-splitting enzymes, but also gives a very useful survey of the biochemistry of bread-making and of the part played by amylases in this process. The article describes the amylases of sound and germinated wheats, the factors affecting the maltose value of wheat flour, and the relation between autolytic maltose production and flour gassing power. The article is an important one, not only for its information on amylases but also for an appreciation of the significance of these enzymes in milling and baking technology.

Another enzyme, adenosine triphosphatase, is the subject of an article by Engelhardt. This article deals with the enzymic properties of myosin, the muscle protein, which is capable of bringing about the hydrolysis of adenosine triphosphate. This molecule "is the last link in the long chain of reactions which make available for the performance of mechanical work the chemical energy enclosed in the carbohydrate molecule. The principal agent that performs this work is the protein, myosin, which constitutes by far the predominant part of the solid structure of the muscle fibre and which is unanimously regarded as the contractile substance of muscle." Engelhardt's article gives a detailed description of the purification and crystallization of adenosine triphosphatase, and of the stimulating work of Szent-Györgyi and his colleagues in this field of muscle chemistry. The article not only deals with the characteristics of the enzyme activities of myosin but goes on to the discussion of "mechano chemistry", a term which is meant to embrace those physical, or physico-chemical, changes undergone by the contractile substance of muscle, which are related to its mechanical properties and which are induced by substances produced by the "functional metabolism of muscle tissue". It appears to be manifest that the union between myosin and its substrate, adenosine-triphosphate, brings about physical changes in the protein which are directly connected with muscle contraction. A new phase in our knowledge of muscle chemistry has opened up, and Engelhardt's article is a good introductory survey.

Muscle chemistry also forms the subject of an interesting article by Hoagland of the states of altered metabolism in muscle diseases. When it is realized that striated muscle makes up about 42 per cent of the total weight of the body, and that so much fundamental information concerning normal mechanisms in this organ is known, it seems strange, as Hoagland says, that so little should be known of the biochemical origins of muscle diseases. Hoagland describes succinctly what is known of the metabolic changes in muscular atrophy and hypertrophy, and the degenerative changes in muscle due to deficiency of vitamin E. He discusses, from the point of view of metabolism, the grave muscular diseases of myasthenia gravis, myotonia, familial periodic paralysis, and progressive muscular dystrophy.

Biological antagonisms between structurally related compounds form the subject of a stimulating article by Dr. D. W. Wooley. The biological competition between structurally related molecules, first discovered in the study of enzyme systems, has become of great importance in the search for substances that will affect the growth and metabolism of micro-organisms. The successes and the failures which have attended efforts to evolve microbial antagonists, by creating molecules the chemical structures of which are related to those of substances known to be essential for the metabolism of the bacteria, for example, the vitamins, are described by Hoagland. He indicates the various possibilities and limitations of the present lines of inquiry.

Dr. M. G. Sevag writes a long and interesting article (94 pages with 218 references) on enzyme problems in relation to chemotherapy, which cannot be adequately summarized here. The article should be read by all concerned with investigations of biological antagonisms, of the effects of biological inhibitors on enzyme systems, of adaptive enzymes, of mutations induced by toxic agents and of other relevant phenomena. Dr. Sevag states that it has been his aim "to present the action of toxic or bacteriostatic agents, mutations, resistance and immunity as interrelated processes in micro-organisms". He concludes that the experimental data pertaining to the action of toxic or bacteriostatic agents seems to show that their effects are primarily on the respiratory enzymes. His article, without doubt, merits close attention by all workers interested in the bearing of enzyme chemistry on chemotherapy.

Dr. C. E. Clifton presents an able summary of our present knowledge of microbial assimilation, the process in which synthetic operations occur in the cell simultaneously with breakdown (chiefly oxidative) processes. His objective is "to consider the studies dealing with the assimilatory processes of nonphotosynthetic micro-organisms and to attempt as far as possible to correlate observations on the relation between the anabolic and catabolic activities of microbial life". Dr. Clifton gives a detailed and valuable account of many experiments (including some of those of himself and his colleagues) on the oxygen consumptions of resting, or washed suspensions, of bacteria in presence of organic compounds and on the simultaneous assimilation of a portion of the substrate by these organisms.

All biochemists interested in the significance of acetyl phosphate in intermediary metabolism will do well to read Dr. F. Lipmann's article on this subject. Use of the isotope technique has thrown acetic acid into prominence as a probable source, in the body, of complex organic molecules. Lipmann's work on acetyl phosphate shows a possible way in which acetic acid is likely to enter into the synthetic operations of the cell.

Limitations of space forbid more than mention of the interesting article by Dr. K. C. D. Hickman and Dr. P. L. Harris on tocopherol interrelationships, in which they examine the physiological activities of the E vitamins in terms of oxidation control and conclude that α-tocopherol has a more fundamental function, at present not understood. Nor is there room to describe the lengthy (79 pages, 355 references) but most instructive article by Dr. Frankenburg on the chemical changes in the harvested tobacco leaf. Indeed, this article deals only with those changes attending the curing process; a later article will deal with the changes taking place during fermentation.

J. H. QUASTEL

MATHEMATICS OF STATISTICS

Mathematical Methods of Statistics

By Prof. Harald Cramér. (Princeton Mathematical Series, 8.) Pp. xvi+575. (Princeton, N.J.: Princeton University Press; London: Oxford University Press, 1946.) 33*s.* 6*d.* net.

A First Course in Mathematical Statistics

By Prof. C. E. Weatherburn. Pp. xv+272. (Cambridge: At the University Press, 1946.) 15*s.* net.

THESE two books at once invite comparison with Maurice Kendall's "Advanced Theory of Statistics" and A. C. Aitken's "Statistical Mathematics". All four are mathematically flawless, and they all require from the reader some mathematical training and ability, but not to the same extent, nor are they all addressed to quite the same category of scientific workers. Kendall, in his preface, called his "a book on statistics, not on statistical mathematics" and declared his intention "to keep the mathematics to heel". Cramér's book (based on his Stockholm lectures since 1930) is very definitely for the mathematician, and its avowed purpose is to join the two lines of development due on one hand to the British and American schools of statisticians, and on the other to the rigorous work of French and Russian mathematicians in developing the calculus of probability. The first twelve chapters are a purely mathematical introduction, dealing with the properties of sets, Lebesque integrals, Fourier integrals, matrices and quadratic forms, and the like, preparatory to the later chapters on random variables, probability distributions, and statistical inference. The author advises the reader to jump to Chapter 13 after reading the first three chapters and a few other paragraphs, and thereafter to use this earlier part only as needed. The advice is good, and for my part I would say jump to Chapter 13 at once. Many who ought to read the book would be highly discouraged by the apparent irrelevance of those first three chapters, yet might turn to them without dismay later after seeing their use and necessity.

Weatherburn says in his preface, "the subject treated in the following pages is best described not as Statistical Methods but as Statistical Mathematics, or the mathematical foundations of the interpretation of statistical data". His book does not make such demands on mathematical ability as Cramér's, and is addressed more to practitioners. It is indeed based on lectures to graduates and undergraduates whose researches and studies were in agriculture, biology, economics, psychology, physics and chemistry. They cannot, however, have been a random sample of the students of those disciplines, I imagine. For those who can follow, however, Weatherburn's book is excellent. The chapter on the properties of Beta and Gamma functions, the use of which in discussing tests of significance is a feature of the book, thoroughly justifies the author's claim that it is clear and simple and does not demand any previous knowledge of these functions. Moment-generating functions are used quite a lot (as also by Aitken), in contrast to Cramér's book, where they are never mentioned except possibly in one exercise. I am surprised that the psychologists at least among Weatherburn's hearers did not ask for an earlier treatment of partial and multiple correlation. When he does come to them, he deals very neatly with the maximum correlation between one variable and the weighted sum of two others, and then simply directs attention to the validity of the argument also for *n* others. He does not mention, however, the problem of maximum correlation between two 'batteries' of variables, nor refer anywhere to Harold Hotelling. Neyman, too, receives only a passing reference, in a footnote, and Egon Pearson the same.

I mention these facts about Weatherburn's book not to criticize, but to assist the reader in knowing what to expect in it. Its great virtue is its compactness of argument, which facilitates seeing the whole. For example, he deals with fiducial limits in two paragraphs only, for the fiducial limits of a mean, using σ in the earlier paragraph, and its unbiased estimate s in the later; but the principle is shown clearly, though the words "fiducial limits, or confidence limits" on p. 122 rather suggest a confusion of the theories of Fisher and of Neyman–Pearson. Similarly, the term 'maximum likelihood' occurs only once in the book; but the paragraph which contains it (par. 77) puts the matter with extreme clearness. It may be, however, that anyone not knowing of its importance beforehand would pass over the paragraph without full appreciation. That is the danger of compactness and austerity. Kendall's book is warmer and more inviting.

In his Chapter 34, Cramér, after mentioning the two modern methods of outflanking Bayes' postulate, Fisher's *fiducial probabilities* and Neyman's *confidence intervals*, confines his treatment in the main to an account of the latter theory. In the succeeding chapter, on the general theory of testing statistical hypotheses, he deals further with the Neyman–Pearson theory and its basic idea of trying to reduce the chances *both* of rejecting a hypothesis when in fact it is true, and of accepting it when it is false.

On p. 520 Cramér begins a three-page discussion of the problem which leads to the Behrens test, namely, the problem of determining, from two independent samples, whether the means of two populations differ significantly, their standard deviations being also unknown and not necessarily equal. This is described, in Kendall's book, as a crucial problem for the rival theories of fiducial probability and confidence intervals. I speak with great diffidence, for the matter is difficult; but there does not appear to be any recognition of this in Cramér's book.

GODFREY THOMSON

PHASE-CONTRAST METHODS IN MICROSCOPY

By Prof. L. C. MARTIN
Imperial College of Science and Technology

IF we place, on the stage of a microscope, a slide coated with a thin but opaque metal film pierced by small apertures of distinctive shapes and sizes, there is no doubt as to how its image should appear. We expect to see a dark field surrounding bright areas geometrically similar to the apertures, though on a larger scale. Suppose, however, that the object is a very thin section of some biological structure, for example, a nerve with many component fibres. The various parts of the cellular structure have little difference in their relative transmission for ordinary light, and only differ optically in their refractive indices. What should the image look like ?

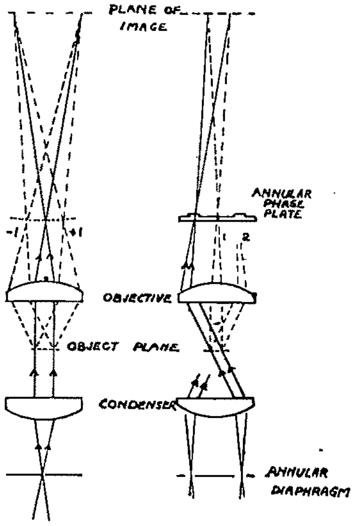
It is known from experience with the first type of object that the exact geometrical relations between object and image are most closely preserved when the numerical aperture of the illumination is adequate to fill the aperture of a perfectly corrected and truly focused objective ; but if we apply such conditions to the 'section', the image will probably give little indication of any object-structure. The microscope is then telling us that there are no considerable differences of opacity in this object.

It is possible to overcome the difficulty by resorting to methods of 'staining', or using, say, ultra-violet radiation of a wave-length for which the structures may show marked differences of transmission ; but both these methods are attended by certain difficulties and disadvantages which need not be detailed here. In spite of their great technical value, they are not always suitable or possible ; thus any method which uses ordinary light, and more or less ordinary microscope equipment, offers much attraction.

Familiar experience shows that if the aperture of the illumination is drastically restricted when viewing such a section, the image will show a pattern in which the distribution of light intensity has at least *some* geometrical relation with the structure of the object in terms of refractive index, but it is not generally clear how the image is to be interpreted in detail, apart from its broader features. Alternatively, dark-ground illumination may be employed, in which a pattern is obtained, again with some broadly similar geometrical features, but with marked differences in the expression of detail and with highly accentuated contrasts. In both images any relatively large areas of uniform thickness and refractive index will be rendered uniformly light and dark respectively in the cases of bright and dark fields; the brightness of the image changes only in regions where there are marked variations of optical path in the object.

Phase-contrast offers a means, within certain limits, of relating the brightness to the magnitude of the optical path and not merely to its changes.

Let us confine attention for the time being to a theoretical case in which the illuminating beam is 'parallel', that is, the numerical aperture is zero. Fig. 1*a* is intended to suggest how the direct light and the diffracted beams meet in the image plane. The diffracted beams are suggested by the broken lines. In such a case it was shown by Lummer that, if the objective aperture were large enough to take in *all* the light transmitted and diffracted by the object, the image would represent the object both in intensity and relative phase ; that is, we should see differences of brightness corresponding to the differences of transmission in the object ; and moreover, if some parts of the object cause a greater optical path than others, the light in the corresponding parts of the image would exhibit a proportionate retardation of phase. However, this is not immediately helpful as regards visual distinction, since the eye cannot pick out such phase differences ; it can only appreciate differences of brightness in the field.



(*a*) (*b*)

Fig. 1

One of the most interesting contributions to the theory of the interference of light which has been made in recent times is the suggestion of F. Zernike that we can render these phase differences visible by adding (or 'subtracting') a uniform background of coherent light. Where the phase of the background agrees with that of the field the brightness will be enhanced ; where the phases are opposite there will be a loss of light. We can look on the light leaving the object plane as 'the unaffected wave *plus* certain diffraction waves produced by the structures'. While the diffracted light is widely spread, the direct light will be brought to something approaching a physical focus in the upper principal focus of the objective before it spreads out to fill the image field and form (together with the 'diffracted' waves) this invisible image expressed in terms of phase variation ; but suppose we place in the focus of the direct beam a thin plate of phase-retarding material (a 'phase strip') so small in area that we can neglect without much error its effect on the diffracted waves. Once more we can apply the above idea ; the wave leaving the phase strip can be regarded as the incident wave plus a wave due to the strip. We thus add (in effect) a uniform background of coherent light to the original image, and the differences of phase of the image (corresponding to difference of path in the object) become visible as differences of brightness.

The above ideas may be symbolized in the vector diagram, Fig. 2, where *OA* represents the amplitude and phase of the incident wave ; it passes through a certain element of the object and is retarded in phase. The result is now represented by *OP*, which we can look upon as the incident wave *OA* plus the diffracted wave *OQ*. Again, the incident wave *OA* passes through the phase strip, where it is retarded by 90°

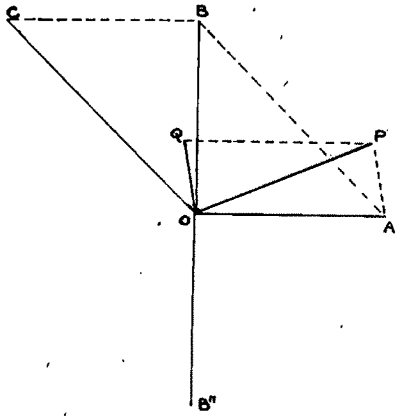


Fig. 2

thus becoming OB (note that OQ is regarded as unaffected). Now OB can be represented by OA plus OC. Thus the final effect can be looked on as due to: (*a*) the incident wave (unaffected) (OA); (*b*) the 'wave' generated by the element (OQ); (*c*) the 'wave' generated by the phase strip (OC). We can look on the 'wave' OC as adding the 'uniform background of coherent light'. In effect, of course, the resultant is the sum of OQ plus OB. This summation is effected in Fig. 3*a*, where the resultant amplitude is represented by OR. Suppose now that various parts of the object exhibit regions of small phase-changes for which the 'diffracted' waves in the above sense are OQ_1, OQ_2, OQ_3, etc. (Fig. 3*b*). Then when the original wave has been subject to the 90° phase change the resultants will be OR_1, OR_2, OR_3, and the corresponding intensities in the image will correspond to the squares of these amplitudes. We shall now have a *differing intensity corresponding to the differing phase*, and this is an important gain. The *relative* differences can be enhanced if the amplitude of the direct beam is cut down at the same time that its phase is changed (this can easily be effected by suitable absorbing material, see below). Then its amplitude can be represented by the shortened line OB^1 (Fig. 3*c*), and the relative amplitudes of the final resultants by OR_1^1, OR_2^1, etc., which have a larger relative variation.

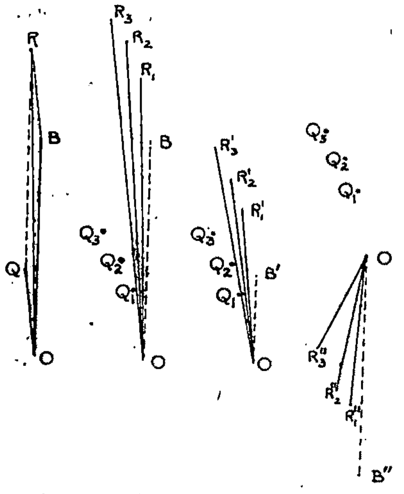

Fig. 3

Again, it is possible so to arrange matters that the phase of the direct light is accelerated with regard to the diffracted waves; then the vector OA (Fig. 2) is shifted to OB^{11}, and it will be clear that the resultants OR_1^{11}, OR_2^{11}, etc. (Fig. 3*d*), have reversed their relative order of magnitude. Hence the contrast is reversed, and the picture will be a negative of the previous one (negative phase-contrast).

The above considerations should help to make clearer the answer to the question which is commonly put regarding phase-contrast. It is this: We are told that in order to establish the best resolution in the image we should employ the widest possible cone of illumination; on the other hand, phase-contrast methods demand a drastic restriction of the numerical aperture of the illumination. Shall we not therefore lose resolution and therewith the truthfulness of the image?

In answer, it is admitted at once that if the object is one consisting mainly of opacity variation, then the best image is obtained by using the widest possible cone of illumination; if good contrast cannot be obtained with such illumination (as compared with the contrast of the object) then the spherical correction of the objective is suspect, or much stray light may be present. On the other hand, one can only speak of resolving power in relation to a 'phase-variation' object when some means exist of making the structure visible to the eye, with some ascertainable degree of geometrical verisimilitude. If we use a narrow aperture and very oblique illumination, we can, it is true, often obtain evidence of reasonably large phase-variation in fine-structured detail as readily as if a similar opacity structure were present, but if the phase-variations are small the possible brightness differences will be very small also. Using the Abbe principle, it can be said that generally if the angle of a parallel illuminating beam is reduced from the greatest possible obliquity to a direction parallel to the axis, the minimum resolvable interval for a regular structure is increased by a factor of approximately 2; but this depends entirely on the presence of a phase-variation in the object of adequate amount; if the phase-variations are very small, there may not be sufficient contrast in the image to obtain visual resolution of the structure in either case. The discussion of the resolving limit for phase-variation structure has thus no meaning apart from the specification of the phase-angles concerned; for these determine the possible visual contrast.

According to Zernike, phase-contrast has no special use where large phase-variations, say 180°, are concerned; it will, on the other hand, easily render visible phase-differences of very small angle, say 5°–10°; moreover, the phase-step is seen as a step of brightness between two uniform corresponding parts of the field, not merely as a halo or dark fringe.

It need not, therefore, be feared that the phase-contrast method must always result in a 'loss of resolution'; unless, indeed, the object is one of mixed opacity and phase-variation, which is a case requiring special study.

In practice, the simplest arrangement for producing phase-contrast would require a central circular aperture stop in the lower focal plane of the condenser; this would produce a roughly parallel beam through the object. The phase-plate then occupies a position, in the upper focal plane of the objective, conjugate to the aperture stop. In order to increase the light available for the image, the stop can be elongated to a broad slit; but directional differences then become

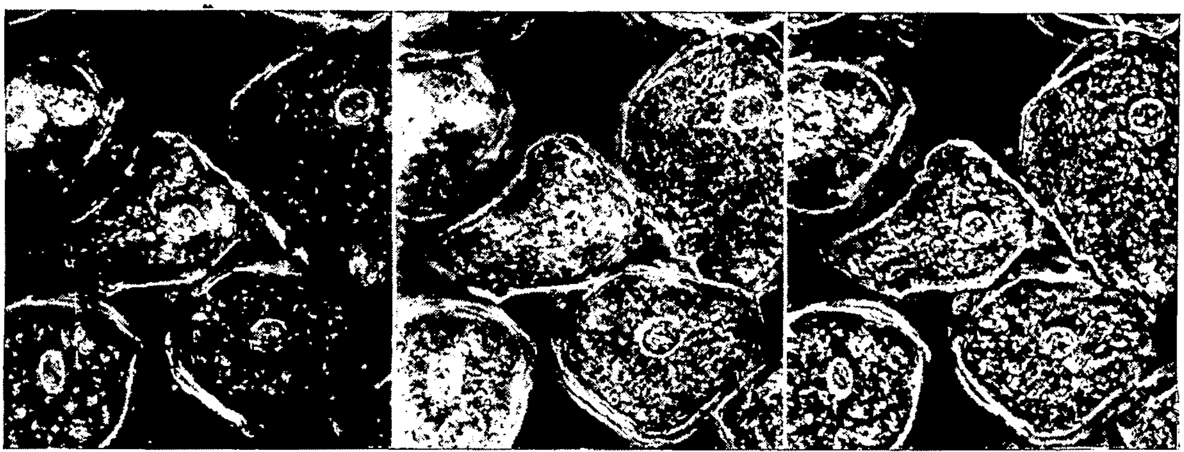

Fig. 4. COMPARATIVE PHOTOGRAPHS OF EPITHELIAL CELLS FROM THE MOUTH. OBJECTIVE, COOKE 4 MM., N.A. 0·65 ; EYEPIECE, COOKE, × 6 ; BELLOWS EXTENSION, 40 CM. ; MAGNIFICATION, × 300. (a) DARK-GROUND ; (b) POSITIVE PHASE-CONTRAST ; (c) NEGATIVE PHASE-CONTRAST. REPRODUCED BY COURTESY OF MR. E. WILFRED TAYLOR

manifest. In practice the most satisfactory form of the condenser stop is thought to be an annular aperture having a mean radius corresponding to about $\frac{1}{2}$ to $\frac{2}{3}$ of the numerical aperture of the objective, and a width about $\frac{1}{15}$ of this aperture. The phase-plate then has a corresponding phase-changing ring, as suggested in Fig. 1*b*. This arrangement is intended to minimize any loss of resolution.

A retarding ring can be made by vacuum deposition of some suitable material, say calcium fluoride, on the surface of a plane parallel plate; such a ring will usually require protection. Rings can be etched into a similar plate with dilute hydrofluoric acid; and we can thus obtain plates in which the diffracted components suffer greater retardation than the direct light; this is equivalent to an acceleration of the direct light, and would give negative phase-contrast.

If it is desired to diminish the intensity of the zero-order component, the area of the phase-ring only may be coated with a thin film of metal, say, aluminium, by vacuum distillation.

Alternatively, strips or rings of the desired form can be cut from nitro-cellulose, gelatine, etc., which can be made 3μ–6μ thick; these may be cemented in a medium having a refractive index differing somewhat from that of the strip. A very precise control of the retardation is thus possible. Gelatine strips can be dyed to give more or less neutral or selective absorption. The upper focal plane of low-power lenses can be furnished with a thin glass plate bearing a suitable ring; but this arrangement will not serve for high powers, where the principal focus may lie within the lens; in such a case the phase-ring may be borne by one of the interior surfaces. It is thus a considerable advantage to have a special set of objectives fitted with such phase-rings. They will not be ideal for use apart from the phase-contrast method, but at any rate if the phase-ring is non-absorbing the disturbance to the phase-relations in an ordinary image will correspond to the well-known 'Rayleigh Limit', which roughly marks the bounds of discriminable effect. Objectives so fitted can be thus used for ordinary purposes with little risk.

Messrs. Cooke, Troughton, and Simms, Ltd., of York, are producing special sets of objectives, together with the accessory condenser apertures, etc., and the method was recently explained and demonstrated by Mr. E. Wilfred Taylor at a meeting of the Royal Microscopical Society. He showed photographs of biological objects involving the discrimination of extremely small path-differences in flagellæ, etc., which were clearly brought out by phase-contrast. It was clear from such photographs that the images obtained may differ considerably from those obtained by normal methods, and careful attention to the interpretation will be necessary.

Still more recently, Mr. Taylor has made and described a new phase-contrast microscope in which a controlled variable amplitude for the 'direct-light' component is obtained. It is thus possible to adapt the instrumental conditions to suit various types of phase-variation in the object detail. Polarized light is employed, and the necessary relative amplitude variation is secured by the use of a plate, built from concentric annuli of right-handed and left-handed quartz, to carry the phase-changing annulus in the upper focal plane of the objective.

It may be possible perhaps to develop some scheme whereby artificial phase-step objects can be made and included in microscope slides of objects to be studied; the photometric scale for such steps could then be established in terms of the corresponding path differences; this would (for a section of known thickness) enable an approximate determination of relative refractive indices to be carried out, which would be a step towards the identification of parts of the structure. Methods of an analogous kind are well known in connexion with doubly refracting materials. The 'artificial objects' could be minute crystallites or photographic step-wedges in gelatine, etc., mounted in balsam of suitable refractive index.

It cannot be said that the practical use of phase-contrast is yet as fully understood as it should be. The theory rests largely on a two-dimensional analysis; even so, it is only partly developed and the exact effects of the annular phase-contrast rings have not yet been fully explored. During the discussion at the Royal Microscopical Society, Mr. J. R. Smiles, of the National Institute for Medical Research, mentioned difficulties in interpretation of the image due to scattering of light by the object. If the object is an infinitely thin lamina, then the 'scattered' light has the phase characteristics of diffracted light, and consists of the boundary waves, etc., generated in the object plane as well as any light suffering molecular scattering; the effects of this are more or less predictable; the waves are diffracted at the circular aperture of the objective, and the phase-strip contributes its effect also. The general effect is to form fine halo and shadow fringes near the boundaries of phase-change in the object. Zernike has discussed similar effects in his papers, showing how it is that small opaque particles may sometimes appear bright on a dark ground, drawing their light from neighbouring parts of the field.

But the problem grows much more complex when the object is thicker; the sum of the diffracted light may have no easily predictable phase-relation with the incident light, and could thus be spoken of as 'scattered' in that special sense. The halo and fringe effect may therefore be complex, and although the broader regions of uniform phase should still be rendered at the appropriate brightness levels in the image, we cannot interpret the fringes in the same way in every case. The statement above, that the brightness of the image field is related to the retardation of the object, does not apply to the variations of brightness in the border fringes, and the possibility of estimating the retardation does not apply to relatively small objects.

Enough has been said to indicate that the practical technique must be studied in relation to special objects. The simple theory only takes the worker a part of the way, and there is room for a considerable amount of further work both theoretical and practical. However, all the evidence shows that 'phase-contrast' is a most valuable addition to the methods available to the microscopist, and it is being intensively studied at the present time. One of Zernike's own papers (*Physica*, 9, 686 and 974; 1942) gives the best starting-point.

MARINE BIOLOGY AT PLYMOUTH*

THE Marine Biological Association of the United Kingdom came into being in 1884 as a result of a meeting held under the chairmanship of Prof. T. H. Huxley, the successive outcome of which owed much to the initiative and energy of Sir E. Ray Lankester. The prime purpose of the Association was "the establishment and maintenance of a well-equipped laboratory at a suitable point on the English coast, similar to, if not quite so extensive as, Dr. Dohrn's Zoological Station at Naples". The suitable point finally selected was Plymouth, and there, under the walls of the Citadel built by Charles II and overlooking the waters of Plymouth Sound, the laboratory building, constructed of the same Devonian coral limestone as the Hoe, was opened on June 30, 1888.

Financial support came initially from members of the Association, from universities and other public bodies, notably the Fishmongers' Company, and from H.M. Treasury. All these sources of income have been maintained and increased, but especially the Treasury grant, which became considerable after 1918, when it was put under the control of the Development Commissioners. In 1902 the Association undertook the British share of the scientific investigations of the International Council for the Exploration of the Sea, which involved the establishment of a second laboratory at Lowestoft for work on the trawling grounds and food fishes of the southern North Sea. After 1918 this laboratory was re-established under the Ministry of Agriculture and Fisheries for work on problems dealing directly with commercial fisheries. The Plymouth Laboratory was to be concerned with the more fundamental problems of marine research, and to this end notable increases were made to the staff, buildings and facilities of the Laboratory in the years between the two World Wars.

The papers published in the *Journal* of the Association, now in its twenty-sixth volume with two earlier volumes in a smaller format, indicate the changing interests and widening scope of the work carried on in the Laboratory. Earlier volumes are largely concerned with observations on the habits of fishes and shellfish and on the methods and results of commercial fisheries. Aided by enthusiastic visiting workers, the basis was also being laid of the extensive knowledge of the marine life of the Plymouth area now recorded in the "Plymouth Marine Fauna" (second edition, 1931). With the assumption of the work for the International Council opportunities came for initial studies on hydrography, on bottom fauna and on plankton. A notable change comes in the subject-matter of the *Journal* after 1918, with emphasis on the study of the chemical and physical conditions of the environment, on the life-histories and development of marine invertebrates and on the distribution in space and time of the animal populations. Nevertheless, research on the biology of fishes continued and provided a necessary link with the more economic investigations being carried out at Lowestoft. But recognition of the value of fundamental research had been achieved. To-day we are approaching the stage when all fisheries research will become increasingly fundamental, aimed at understanding the great natural fluctuations in the fish populations and the causes of the habits of the fish themselves.

The Plymouth Laboratory has provided the basis for such far-reaching studies by the concentration of its work around two main themes. The first is how much living matter can the sea produce, what are the variations and causes of variation in productivity, and how do the organisms obtain the materials necessary for life? The second is how do marine animals live, how do they fit their various environments, and what alterations in the conditions in their environment can they appreciate? The sea water contains all the ingredients needed for successful growth and development of living organisms; it is the conditions in the water which therefore determine their distribution and migrations.

The study of the physics and chemistry of the sea has thus become a major preoccupation. The approximate yearly cycle of the more abundant constituents —phosphorus, nitrogen and silicon—is now known, although much remains to be done on the annual turnover and on periodic fluctuations. This in turn involves a study of water movements, especially of upwelling from deep layers. Plant life depends on light and is limited by the depth of its penetration; this is being studied by methods employing photoelectric cells. Meanwhile, pure cultures of diatoms and flagellates are used as experimental material for determining the utilization of combined nitrogen and phosphorus, and the effect of trace elements such as iron and manganese, which may limit plant production in the sea.

Animal plankton forms the first link of the chain from plant plankton to fish, and researches on its distribution, abundance, growth and habits form a necessary part of the study of the general problem of productivity. The effects of grazing off the plant crops can be studied at sea by evaluation of their numbers in measured volumes of water and also experimentally in the laboratory. Certain species of plankton organisms are restricted to certain types of water, and form most valuable biological indicators of their respective water masses, which are often not easily distinguishable by the usual hydrological features, such as salinity and temperature.

---

* Substance of a lecture by Wing-Commander F. S. Russell, F.R.S., delivered at the Royal Society on March 6.

Bottom-living invertebrates form the food of many fish and are specialized for life in different grades of bottom material, from fine mud to coarse gravel, and normal metamorphosis from the larval stage may only occur on the appropriate substratum. Study of the available food in the different deposits reveals considerable variations. The topography of the sea bottom is also important in connexion with water movements. There are indications that the embayments resulting from submerged valleys may cause submarine waves, with consequent upwelling of nutrient-laden water into the photic layers.

With the exception of insects, all the major groups of animals are represented, many of them exclusively, in the sea. The problems they present for inquiry to the systematist, morphologist, ecologist, parasitologist, embryologist and geneticist are without limit, and so, from this point of view, are the facilities of the Plymouth Laboratory. From a study of structure there is a natural transition to that of life-histories, food and feeding, breeding and growth, and the general relationships between the animal and the environment. Apart from the bearing of such studies on food fishes and shellfish, they provide essential knowledge for combating the activities of marine boring animals and of fouling organisms. During the War the demand for raw material, such as alginic acid, agar and mannitol, from seaweeds, gave a sudden stimulus to research on the life-history and growth-rate of intertidal weeds, of which very little was known. Extension of work into estuarine waters has provided physiological problems of the first importance and data of value in assessing pollution. Finally, by the working out of new methods of collection and analysis, the Laboratory has played an important part in the success of deep-sea expeditions carried out by vessels of many countries.

While the work of the staff at Plymouth is most varied, as revealed in the foregoing brief survey, it is greatly increased by that of the continuous stream of visiting workers from all countries which has always been encouraged in every way possible. To them in particular has been due the increasing volume of physiological work for which the rich supply of animal life provides material often unobtainable elsewhere, such as the spider crab, *Maia*, used for nerve physiology and studies on the respiratory pigment, hæmocyanin, the squids and cuttlefish with their giant nerve fibres, sea anemones with their simple nerve net, and the dogfish which has provided material for elucidation of the function of the lateral line and of the labyrinth.

From the simple beginnings of accommodation, staff and programme in 1888, the Plymouth Laboratory has been gradually raised to its present commanding position among research institutions, above all by the careful guidance of Dr. E. J. Allen, its director for forty-two years, and of his successor for an all too brief period, Dr. Stanley Kemp. With their names will always be associated that of Dr. G. P. Bidder, who has given so generously in wisdom and money. The present buildings can accommodate some forty workers, including the present twelve members of the permanent staff. It possesses an admirable library and an aquarium. There are two research vessels, a 25-ft. motor boat and a 90-ft. motor fishing vessel used for investigations at sea and also for collection of specimens and for stocking the aquarium. During the Easter vacation, they also assist in the courses for students which are so important a feature in the work of the Laboratory, and which have guided many young zoologists into a life-work of fruitful research either in the universities or in marine laboratories.

The Plymouth Laboratory, in the words of its present director, F. S. Russell, "aims to give facilities for any research, not necessarily only biological, on problems for which the sea can provide the materials or the environment required. Its position is unique, lying as it does between the extremes of a fishery research laboratory and of an oceanographical institution, yet serving both, and at the same time offering facilities for visitors like the laboratory at Naples on whose pattern it was first founded. Let us hope it may continue to hold this focal position and attract all those interested in the science of the sea and indeed of life itself."

THE VIENNA ACADEMY OF SCIENCES (1847–1947)

THE "Kaiserliche Akademie der Wissenschaften" of Vienna was founded by Kaiser Ferdinand I on May 14, 1847. Although not a State institution, the Academy is conducted under the ægis of, and is endowed by, the State. It consists of two Sections (Klassen), the Mathematical and Natural Science Section for mathematics, natural science, medicine and technical science, and the Philosophical and Historical Section for philosophy, history and archæology, art and music, language and literature, geography and ethnology, law, political science and economics. The Sections meet separately every fortnight for the consideration and discussion of scientific subjects, and they have a joint session once a month.

The work of the Academy is carried out under the continuous supervision of a commission for each scientific subject or for a particular research undertaking, this commission advising on the equipment, methods and problems of the undertaking, and on the choice of suitable personnel. From the scientific point of view, the main work of the Academy is under the care of its members, and it maintains a scientific liaison with various State institutes, in particular with those of the University of Vienna. Moreover, the Academy has several institutes under its direction, especially on the scientific side.

Each Section of the Academy has 33 members and 80 corresponding members, of whom 35 are Austrians and 45 foreign nationals, and there are also 8 honorary members in each Section. Provision is also made for the election of eight honorary members of the whole Academy, and these would be mostly highly placed dignitaries of the State who have rendered service to research or to the advancement of the interests of the Academy, or distinguished men of learning of national or international repute. Corresponding members are entitled to take part in open meetings of the Sections, but they are not automatically promoted to full membership of the Academy. Places rendered vacant by the death of members or corresponding members are filled at the annual elections, and membership is only possible by election.

During the past hundred years, the activities of the Academy have been many and varied. In the Mathematical and Natural Science Section, a beginning was made in 1849 with meteorological observations in Austria, and these laid the foundation for the establishment of the Zentralanstalt für Meteorologie und Geodynamik, now a State institution, but with which the Academy still maintains close scientific connexion. Measurements of gravity in Austria in relation to geotectonic structure have been carried out, a magnetic survey of the country has been made, and investigations on atmospheric electricity have been undertaken. Furthermore, the Academy has taken part in Polar expeditions and fitted out the station on Jan Mayen Island (off Greenland) in the years 1882–83 and 1932–33. In the years 1867–79 investigations of a hydrographic and physical nature were carried out in the Adriatic, and during 1890–98 expeditions were sent to the Eastern Mediterranean (north of Crete), to the Sea of Marmora and to the Red Sea for hydrographic and geophysical observations, for the chemical and physical investigations of the water, and for the collection of zoological specimens. In 1901 a botanical expedition was sent to Brazil, and one for zoology in 1903.

On the scientific side, the Academy administers wholly or in part a number of research institutions. The Institut für Radiumforschung (Vienna Radium Institute) was founded in 1910 and possesses 4 gm. of radium chloride for research purposes. From among its past activities may be mentioned the provision and certification (jointly with Paris) of radium standards, the development of methods of measurement, investigation of the various radioactive radiations and the effects of radioactive substances, the isolation and properties of the radio-elements, and work on isotopy. The years between the two World Wars were characterized primarily by K. Przibram's work on crystal physics, and a large amount of work was done in the Institute on problems connected with artificial transmutation (by Pettersson, Kirsch, Ortner, Stetter, Blau and others). At the Biologische Versuchsanstalt in Wien (Prater), experimental zoological and botanical work was carried out between 1913 and 1941, more especially on *Entwicklungsmechanik* and research on regeneration. The Station was damaged during the War, and its director and co-founder, Hans Przibram, was a war victim and died in a concentration camp. The Biologische Station in Lunz investigates the plant and animal world from the point of view of biology and ecology in the three Alpine lakes and in the neighbourhood accessible from the Station. The Academy also has Höhenobservatorien (mountain observatories) on the Sonnblick (Hohe Tauern, 3,100 m.), and on the Obir (2,000 m.) in the Karawanken, south-east of Klagenfurt.

The Philosophical and Historical Section of the Academy has conducted research in the field of Austrian history back to prehistoric times. It has carried out prehistoric excavations and investigations on monuments from Roman times, and has published "Quellen zur österreichischen Geschichte" (Sources of Austrian History) dating back to the early Middle Ages. Between 1900 and 1910 research expeditions were sent to Southern Arabia for linguistic purposes, and likewise to Palestine and Transjordan for archæological studies. It has also published a *corpus* of ecclesiastical writers in Latin, as well as records of Greek and Roman inscriptions of Asia Minor resulting from journeys of exploration in that region. Furthermore, excavation of an extensive cemetery near Giza, in the neighbourhood of the Great Pyramids, yielded important results on the history of architecture and sculpture of the Old Kingdom in Egypt. Linguistic and archæological investigations in the Balkans have have also been undertaken.

Among the institutes under the control of the Academy there is also a Phonogrammarchiv (Gramophone Library), equipped with the most modern methods of recording, and here are housed a large number of speech records of most of the world's living languages, vocal 'portraits' of important historical Austrian personages and representatives of the stage, together with interesting medical records on rare defects in speech.

In the realm of natural science, the Academy has the names of many distinguished men of science on its roll, including the mathematician Wilhelm Wirtinger, the physicists Loschmidt, Boltzmann, Franz Exner, Ernst Mach and Stefan, the chemist Auer von Welsbach, the geologist Eduard Suess, the botanists Richard Wettstein and Hans Molisch, and the medical scientists Karl Rokitansky (pathological anatomist), Sigmund Exner (physiologist) and Theodor Billroth (surgeon).

The Academy issues the following publications: *Denkschriften der Gesamtakademie* (Vol. I: History of the Academy, 1847–1947, by the present vice-president, Prof. R. Meister), *Almanach* (annual reports of the Academy), *Anzeiger* (preliminary notices) of the two Sections (annual reports of activities). Scientific papers in each Section are published in *Denkschriften* and in the *Sitzungsberichte*.

It is not generally known that the Vienna Academy rendered incalculable service in two directions in the early days of radioactivity. When it was realized that there were other radioactive substances than uranium and thorium present in pitchblende, it seemed probable that these would be found in the uranium residues resulting from the extraction of uranium, of which large quantities lay derelict at St. Joachimstal in Bohemia. The French approached Suess, who was president of the Academy at the time, and through his intervention with the Ministry of Agriculture, two wagon loads of the residues were dispatched free of charge to Paris. It was from this material that the Curies isolated the element radium and prepared the Primary International Radium Standard, and it has been estimated that 60,000 kgm. of these residues contained a total of about 24 grams of radium. The second instance concerns the loan by the Academy of about 400 milligrams of radium to the late Lord Rutherford; it was primarily with this material that most of the work of the Rutherford Schools at Manchester and Cambridge was carried out. After the First World War, Lord Rutherford purchased this radium from the Academy in annual instalments, and as a direct result the Vienna Radium Institute was enabled to carry on through the first lean years of peace.

On the recommendation of Prof. H. Mache, of the Technical High School, it was my happy privilege to work in the Vienna Radium Institute during 1913–19. That grand old man of science, the spectroscopist Franz Exner, lovingly known as 'Väterchen', was the representative of the Academy in the Institute, and Stefan Meyer made an ideal director. It is good to know that, after a break of several years, he is again directing the Institute, and that Karl Przibram is also there. Imbued with the spirit of the Exner School, Meyer was ever ready to place at the disposal of his fellow-workers his stimulating ideas and great wealth of experience as a pioneer and fruitful worker in the field of radioactivity. At the outbreak of war in 1914, and with the backing of the Academy, he successfully appealed for my release as a civilian prisoner of war, and as a result my work in the happy family atmosphere of the Institute continued throughout hostilities. During these years much of the pioneer work on isotopy and on tracer elements (radioactive indicators) was carried out in the Institute (Hevesy and Paneth), and the atomic weights of lead of radioactive origin and of other radioactive elements were accurately determined by Hönigschmid. Several Polish refugees worked in the Institute at that time, including Godlewski, Loria and Patkowski. Work on the counting of radioactive rays was actively pursued, mainly in collaboration with the chief assistant, V. F. Hess, discoverer of cosmic rays (1912). It is of interest to note that two of the members of the Institute later received the Nobel Prize (Hess and Hevesy), the latter also being elected a foreign member of the Royal Society, and quite recently Paneth (now at Durham) has been elected to fellowship of the Society. I shall be ever grateful for the friendly and cordial way in which I was received into the fellowship of the Radium Institute of the Academy, the stimulating and fertile influence of whose members was alone responsible for my being able, as an enemy alien in those eventful years, to publish twenty-three scientific papers, sixteen of which were presented to, and accepted without hesitation by, the Academy for publication in the *Berichte*.

I have much pleasure in acknowledging the help given me by the vice-president of the Academy, Prof. R. Meister, who supplied much of the information contained in this article. I am also indebted to Akademierat Dr. W. Oberhummer and to my old friend Hofrat Prof. H. Mache for additional information.

ROBERT W. LAWSON

CENTENARY CELEBRATIONS

The centenary of the Academy was celebrated in Vienna during the week beginning May 11. After the reception of guests in the Academy on the previous evening, the proceedings began on Monday, May 12, with a meeting of the Historical and Philosophical Section. The meeting was opened by the vice-president, Prof. Richard Meister, and after submitting the report of the Section, the general secretary, Prof. Josef Keil, described the work of the Austrian Archæological and Philological Expedition to the Balkans, Asia Minor, Arabia and Egypt. In the evening, there was a performance of Hoffmansthal's "Jedermann" given in the Ronacher Theatre, since the Burgtheater had been damaged by bombing. The meeting of the Mathematical and Science Section was opened on the following day by the president, Prof. Heinrich Ficker, and after the report had been presented by the secretary, Prof. Adalbert Prey, a historical account of the meteorological and geophysical work of the Academy was given by Prof. Ficker.

On May 14 the main ceremonial meeting was held in the great hall of the Academy. The ceiling, which had been damaged by water, has been restored, and this hall, with its magnificent baroque interior, made a fine setting for the distinguished gathering. The president of the Academy, in opening the ceremony and in welcoming the guests, pointed out that the Academy, which once belonged to a great country, now belongs to a small one, but that he hoped it would maintain, on the intellectual level, the characteristics of a great country. The President of Austria, Dr. Karl Renner, who had recently been elected an honorary member, then addressed the meeting, and stressed the importance of the freedom of science and research, and its independence from political influence or ideas. The Austrian Chancellor, Dr. Leopold Figl, then spoke. He referred to the role of Austria in the past as a mediating influence between East and West, and hoped that, in the present times, this could be taken up again. After a speech by the Minister of Education, Dr. Felix Hurdes, the congratulatory addresses from foreign societies were presented. In spite of the difficulties of travel, a number of learned societies sent delegates to attend in person: these included the British Academy (Sir Charles Webster); Royal Academy of Brussels (Prof. Henry Gregoire); Cambridge Philosophical Society (Dr. F. P. Bowden); Czech Academy of Sciences (Dr. Viktor Trkal); Papal Academy of Sciences, Rome (Prof. Ernst F. Petritsch); Paris Academy of Sciences (Prof. Charles Jacob); Polish Academy of Sciences (Prof. Tadeusz Kowalski); Swedish Royal Academy of Sciences (Dr. Orvar Nybelin); Swedish Royal Scientific Society (Prof. Einar Löfstedt); Swiss Academy (Prof. A. von Muralt); and Hungarian Academy of Sciences (Prof. S. Domanovsky). Congratulatory addresses and telegrams were also received from learned societies throughout the world.

The president then announced the election of new members and the award of prizes. Dr. Karl Renner was elected the sole honorary member of the whole Academy. Of the Mathematical and Science Section, J. Radon and W. Schwarzacher were elected full members; E. Hubble and P. Niggli, foreign honorary members; Sir Henry Dale, A. Ernst, O. Hahn, E. Hertzsprung, H. Pettersson and F. Vening-Meinesz, foreign corresponding members. Of the Philosophical and Historical Section, R. Köstler and K. Mras were elected full members; A. Dempf, I. P. Dengel and C. Rauch, Austrian corresponding members; P. F. Jouguet and Gilbert Murray, foreign honorary members; and C. Borren, B. Croce, S. Eitrem, H. Kelsen, G. Mercati and C. Samaran, foreign corresponding members. The Grillparzer Prize was awarded to Rudolf Holzer; the Fritz Pregl Prize to Heinz Holter; the Haitinger Prize to Prof. Berta Karlik, who worked for a time at the Royal Institution, London; and the Rudolf Wegscheider Prize to Prof. Alfons Klemenc. The meeting closed with an account, given by the vice-president, Prof. Meister, of the history of the Academy during the hundred years of its existence; the first award of the Jubilee Prize was made to him for his "Geschichte der Akademie der Wissenschaften in Wien, 1847–1947".

In the evening, there was a special performance by the State Opera Company of "Figaro", given in the Redoutensaal of the Hofburg. It was a remarkable performance, sparkling with life and gaiety, and it seemed typical of the gay courage of the Viennese and Austrian people that such an art could flourish in spite of the present hardships and the distress and misery of the past few years. On May 15 there was an excursion to the Benedictine Monastery at Melk, and to the Biological Station at Lunz. The Station is beautifully situated near the lake in the hills, and the surrounding fields were thick with wild narcissi and spring flowers. On the last day there was a visit to the National Library, followed by a lunch on the Kahlenberg, given by the Mayor of Vienna, and a farewell gathering in the evening in the Rathauskeller.

The visiting delegates naturally found great pleasure in establishing once more normal human relationship with their colleagues, and took the opportunity of visiting their laboratories. Even in the buildings which have not been damaged, the difficulties of carrying on with work are considerable. The problem of fuel for heating the buildings and laboratories throughout the severe Viennese winter is a serious one. Last winter, for example, in the physical and chemical laboratories, no fuel was available; and unless some can be obtained for the coming winter, much of the practical teaching and of the research work must again come to a standstill. No apparatus can be obtained to replace that which has been destroyed or stolen, and the lack of chemicals and the impossibility of getting any is a severe handicap both to teaching and to research. In all departments, the inability to get current publications or books from other countries is considered to be one of the most urgent problems. Action on this is being taken by the British Council and other bodies, but this necessarily takes time, and at the moment there is very little scientific literature available. It was impressive to see how the pursuit of knowledge and the arts, and interest in things of the spirit, took precedence over the material discomfort and struggle of living.

The celebrations were an unqualified success, and, considering the grave material difficulties, it was a remarkable achievement on the part of the secretaries of the Academy and the organisers. There is no doubt that the success owed much to the genial and commanding personality of the president, Prof. Ficker. F. P. BOWDEN

OBITUARIES

Prof. H. S. Jennings

THE death of Prof. H. S. Jennings, just after his seventy-ninth birthday, at Santa Monica, California, on April 14, has removed the most venerable figure from the ranks of students of the physiology and genetics of the Protozoa. His passing marks the end of an epoch.

Herbert Spencer Jennings, son of George Nelson Jennings, was born at Tonica (Illinois) on April 8, 1868. He graduated B.S. at Michigan in 1893, and afterwards held several different posts in other American universities. He took the degrees of A.M. (1895) and Ph.D. (1896) at Harvard, and after further wanderings settled at Johns Hopkins. Here he was appointed professor of experimental zoology in 1907, and became director of the zoological laboratory three years later (1910). He occupied this position with distinction until his retirement as professor emeritus in 1938, when he went to prolong his life's work—as a 'research associate'—at the University of California at Los Angeles. His name is therefore especially linked with Johns Hopkins, though he worked in many other places and received degrees and honours from many other American universities. His first wife—he married twice—was Louise Burridge, who assisted in the illustration of his publications.

During 1896–97 Jennings studied at Jena under Max Verworn, whose "Allgemeine Physiologie" (first published in 1894) was then arousing much interest among zoologists. Verworn was a pupil of Haeckel, and his book was not inaptly labelled by Rádl "the first—and probably also the last—Darwinistic physiology". Yet there can be little doubt that Jennings's brief residence in the stronghold of Haeckelism favourably influenced all his subsequent researches. After numerous preliminary papers he finally produced—while at Philadelphia—his famous "Behavior of the Lower Organisms" in 1906; and this is now generally accepted as a classic of protozoological physiology.

His studies on the physiology of *Paramecium* gradually led Jennings to investigate variation and heredity in this and other ciliates. A long series of papers—from 1907 until the end of his life—records the results of his accurate and admirable experiments. It is impossible to review these here, but most of his general conclusions will be found in his book "Life and Death, Heredity and Evolution in Unicellular Organisms" (Boston, 1920), his review "Genetics of the Protozoa" (*Bibl. Genet.*, vol. 5, 1929), and the article on "Inheritance in Protozoa" which he contributed to "Protozoa in Biological Research" (edited by Calkins and Summers, 1941; reviewed in *Nature*, vol. 149, p. 149; 1942).

Jennings's own labour, and that of his many pupils in similar fields, covered a restricted area but dug very deeply. It is still doubtful, however, how far their findings, in the intensive study of such highly specialized and peculiar organisms as the Ciliata, can be utilized for generalization in the larger domain of genetics. But taken as a whole, the extensive published work of H. S. Jennings does not belie the promise in his forenames: it is all distinguished by a sound philosophical outlook and profound appreciation of the value and scope of scientific method. Consequently, much that he did and wrote will withstand the test of time; and though all his conclusions may not ultimately prove correct, his experiments and his reasonings will undoubtedly endure as a solid basis for the researches of a newer generation. CLIFFORD DOBELL

Mr. G. H. Tipper

GEORGE HOWLETT TIPPER was born in Kendal in 1881, and educated at Kendal Grammar School and Clare College, Cambridge. He entered the Geological Survey of India in 1902. Apart from service in many parts of India, he went to Burma, the Andaman and Nicobar Islands; he travelled through Baluchistan and across Persia and spent three years in Chitral. During the First World War he served with the Bikanir Camel Corps in Egypt and the Libyan Desert and was in France for a short time. He was eventually recalled to help with the production of mica, a mineral in which he had already specialized. From this time he became keenly interested in its mining and preparation for industry, working at the mines themselves and even learning the technique of trimming and splitting.

Tipper had several severe attacks of malaria while abroad and retired after twenty-five years service in 1927. After visiting mica mines in Rumania and a period of travel in Canada and the United States, he married Dr. C. F. Elam, the well-known metallurgist, and retired to Cambridge with the view of working on the fossils he had collected in Chitral. However, he was soon invited to act as a minerals adviser to the High Commissioner for India, where his wide experience and exceptional memory were invaluable.

At the outbreak of war in 1939, Tipper went for a short time to the Department of Economic Warfare and thence to the Ministry of Supply as 'the acknowledged expert of experts' on mica. In 1941 he went as a representative of Great Britain and the Government of India to the United States to help in the organisation of supplies of mica on both sides of the Atlantic, and was attached to the British Raw Materials Mission in Washington. Altogether, he made the double crossing of the Atlantic four times during the War; he flew to India via New Zealand and Australia and also to Brazil. This last trip was a particularly arduous one. On his return to Great Britain, he continued at the Mica Control and eventually became director, until he was compelled to resign on account of ill-health in October 1946. His services were so much valued by the Board of Trade that he was retained as a consultant until his death on April 23, 1947.

Tipper combined the rare qualities of the trained geologist with an intimate acquaintance of the mica trade in all its aspects; but he could not have carried out his war-time work with such success if his complete honesty had not made him trusted and liked by everyone. His devotion to his work compelled him to embark on a series of journeys which many a younger man would have found exhausting, and kept him at work when he was already in bad health. One of his colleagues writes: "I don't suppose that the State ever received more selfless service from a man of great ability than England got from him".

Dr. Leopold von Portheim

The botanist, Dr. Leopold von Portheim, died in London on May 21. He had been seriously ill for some time. Portheim was born in Prague on February 7, 1869, and studied botany there and at Vienna, where he was a pupil of Dr. Julius von Wiesner. He thus lived to be one of the last surviving botanists who were trained by this great master.

One of the most notable achievements in which Portheim took a leading part was the foundation of the Biologische Versuchsanstalt in Vienna in 1901. In this he was associated with Prof. Hans Przibram and Prof. Wilhelm Figdor. The Institute founded by these biologists later became an important centre for research into the physiology of plants and animals. After the First World War the laboratory was presented to the Academy of Sciences in Vienna, Portheim being director of the department of botany. The Institute was destroyed during the Second World War.

When Austria fell under Nazi domination, Portheim's botanical career in that country came to an untimely end, for he was forced to leave the institute which he himself had helped to found, and he fled from the country. Arriving in Great Britain in December 1938 with a note of introduction from the famous Swiss botanist, Carl Schröter of Zurich, he was given hospitality at the Jodrell Laboratory at the Royal Botanic Gardens, Kew, by the late Sir Arthur W. Hill, who was then director of the Gardens. He continued to work at Kew until afflicted with the illness from which he died.

Although his work is not very familiar to British workers, Portheim published papers dealing with plant physiology and related subjects. During the First World War his investigations were concerned especially with the production of fats by some of the lower fungi. He also studied the influence of light on the growth of plants, and later became interested in the action of plant growth substances. The researches on heteroauxin which he started in Vienna were continued at Kew, where he also performed the remarkable achievement of keeping various members of the xerophytic Cactaceæ alive, and caused them to flower in jars of tap water during a period of about five years. He also did some experimental work on antibiotic substances. During his time at Kew he was severely handicapped by poor eyesight, which made it impossible for him to use a microscope. Nevertheless, the extreme care and patience with which he followed his experiments were most praiseworthy, while his attention to detail was such that not even the most trivial facts escaped his notice.

Portheim, who travelled extensively in Europe and also visited the United States, was a man of great personal charm and kindliness, while he was endowed with a keen sense of humour. His extreme modesty and retiring disposition undoubtedly led many to under-estimate his wide knowledge of the physiology of plants. Those who were privileged to know him more intimately found him to have a wide and cultured outlook and to be a firm friend. He will for long be remembered by all who worked at the Jodrell Laboratory while he was there. He leaves a widow and married daughter. C. R. METCALFE

Prof. J. Velíšek

By the death of Dr. Joseph Velíšek, professor of physical chemistry at Brno Technical College, on February 2, Czechoslovakia is deprived of another comparatively young and energetic teacher and investigator. Velíšek was only fifty years of age and had not long succeeded Prof. Baborovský, whose assistant he had been for many years. In 1922–23 Velíšek, under Jorissen at Leyden in Holland, investigated the influence of the vapours of non-inflammable liquids on the explosion limits of methane–air mixtures. His other scientific work included a special study of the hydration of lithium ions, the electro-osmosis of alkali chlorides and other salts through porcelain diaphragms, the use of calcium for electrodes and an examination of the 'turbulent' or 'hydraulic' flow of liquids. Prof. Velíšek was a keen amateur cinematographer. J. G. F. DRUCE

WE regret to announce the following deaths:

Mr. B. Hilton Barrett, lecturer in geology in the University of Glasgow for nearly thirty years, on June 9.

Dr. D. E. Lea, reader in radiobiology in the University of Cambridge, on June 16, aged thirty-seven.

Prof. Philip W. Schutz, professor of chemical engineering in the University of California, known for his work in chemical engineering thermodynamics and dielectric heating, on March 7, aged thirty-eight.

Prof. A. F. Bernard Shaw, professor of pathology in the University of Durham, and during 1933–38 professor of pathology in the Egyptian University, Cairo, on June 3, aged fifty-eight.

NEWS and VIEWS

King's Birthday Honours List

The following names of scientific men and others associated with scientific work appear in the King's Birthday Honours List:

Baron: Sir Roy Lister Robinson, chairman of the Forestry Commission.

C.H.: J. W. Robertson Scott, author, founder and until recently editor of *The Countryman*.

D.B.E.: Miss Caroline Haslett, for services to the Board of Trade and Ministry of Labour.

Knights: Dr. William Norwood East, for services to the study of criminal psychology; R. R. Enfield, chief economic adviser, Ministry of Agriculture and Fisheries; Prof. D. D. Henderson, professor of psychiatry, University of Edinburgh; Prof. E. L. Kennaway, lately director of the Chester Beatty Research Institute, Royal Cancer Hospital, London; Dr. A. McCance, deputy chairman and joint managing director of Messrs. Colville's, Ltd., Glasgow, a member of the Advisory Council to the Committee of Privy Council for Scientific and Industrial Research; Prof. A. Plant, Sir Ernest Cassel professor of commerce with special relation to business administration at the London School of Economics and Political Science, for services to Government Departments.

C.B.: Dr. E. T. Paris, principal director of scientific research (defence), Ministry of Supply.

C.S.I.: J. P. Mills, adviser to the Governor for Tribal Areas and States, Shillong, Assam; V. K. Maitland, chief conservator of forests, Central Provinces and Berar.

C.M.G.: R. W. Thornton, agricultural adviser to the High Commissioner for Basuto, the Bechuanaland Protectorate and Swaziland, and director of the Native Land Settlement Department, Swaziland; R. Watson, director of agriculture, Burma.

C.I.E.: W. G. Dyson, chief conservator of forests, Madras.

C.B.E.: J. E. C. Bailey, managing director of Baird and Tatlock, Ltd.; G. L. Brown, of the National Institute for Medical Research, London, for services to medical research in the Royal Navy; O. F. Brown, assistant secretary, Department of Scientific and Industrial Research; N. S. Clouston, lately commissioner of lands and director of surveys, Nigeria; R. R. Glanville, director of agriculture, Sierra Leone; J. H. Gunlake, lately assistant statistical adviser, Ministry of Transport; Dr. J. A. Gunn, director of the Nuffield Institute for Medical Research, University of Oxford, and chairman of the British Pharmacopœia Revision Committee; H. L. Kirke, head of the Research Department, B.B.C.; Prof. T. D. J. Leech, dean of the Faculty of Engineering, Auckland University College; J. R. Lumsden, chairman of directors, Highland and Agricultural Society of Scotland; Prof. J. A. Prescott, director of the Waite Agricultural Research Institute and chief of the Division of Soils, Council for Scientific and Industrial Research, Australia; F. A. Secrett, technical adviser on vegetable production, Ministry of Agriculture; J. M. Wordie, for services to exploration in the Antarctic.

Jacksonian Professorship at Cambridge: Dr. O. R. Frisch, O.B.E.

Dr. O. R. Frisch has been appointed to the Jacksonian professorship of natural philosophy in the University of Cambridge in succession to Dr. J. D. Cockcroft. Dr. Frisch was born in 1904 in Vienna and was educated at the University of Vienna during 1922–26. He worked on photometry and interferometry at the Physikalisch Technische Reichsanstalt in Berlin between 1927 and 1930. He then took up work with Prof. Otto Stern on experiments with molecular beams. With Stern he determined by this method the magnetic moment of the proton and studied the diffraction of helium atomic beams by crystal faces. During 1933–34 he worked for a year with Prof. P. M. S. Blackett, and then for five years with Prof. Niels Bohr at Copenhagen. With L. Meitner he was the first to demonstrate by experiment in an ion chamber the physical nature of nuclear fission. He went to Birmingham in 1939. In the spring of 1940, with Prof. R. E. Peierls, he worked out the possibility of producing an atomic bomb by the fission of U235, and thereafter worked on this project for the British Government. In 1943 he proceeded to Los Alamos as part of the British team working with the U.S. Atomic Energy Project, and carried out important experimental work on the atomic bomb. For this work he was awarded the O.B.E. in 1946 and the Medal of Freedom with Bronze Palm (U.S.) in May 1947. Dr. Frisch has been deputy chief scientific officer in charge of nuclear physics at Harwell since 1946. By his election to the Jacksonian professorship, the Cambridge school of nuclear physics is assured of distinguished leadership.

Physics at St. Andrews: Prof. J. F. Allen

The vacancy in the chair of natural philosophy in the United College, St. Andrews, due to the acceptance last year by Prof. J. T. Randall of the Wheatstone chair of experimental physics at King's College, London, has now been filled by the election of Dr. J. F. Allen, of St. John's College, Cambridge, to the post. Dr. Allen is a graduate of the Universities of Manitoba, Toronto and Cambridge, and has been a research assistant in the Royal Society Mond Laboratory, Cambridge, where he conducted research on liquid helium and on magnetic cooling. During the war years he was engaged in work on behalf of the Ministry of Aircraft Production and the Ministry of Supply. It is anticipated that he will continue low-temperature research in a new laboratory to be built at St. Andrews.

Royal Aeronautical Society: Dr. H. Roxbee Cox

Dr. H. Roxbee Cox has been elected president of the Royal Aeronautical Society for 1947–48, and takes office on October 1, 1947. Dr. Roxbee Cox, who was born in 1902, obtained first-class honours in engineering and took an advanced course in aeronautics at the Imperial College of Science and Technology, London. In 1924 he joined the Royal Airship Works. Four years later he was awarded the R.38 Memorial Prize of the Society for his paper on "The External Loads on an Airship Structure". Following the Government decision to discontinue airship work, Dr. Roxbee Cox returned to the Royal Aircraft Establishment, renewing his work on wing flutter, aircraft structures and aerodynamics, and in 1936 became head of the Air Defence Department at the Establishment. In 1938 he was appointed chief technical officer to the Air Registration Board, and on the outbreak of war seconded as superintendent of scientific research at the Royal Aircraft Establishment. In 1940 he became deputy director of scientific research in the Air Ministry, paying special attention to jet propulsion gas turbines; at the Ministry of Aircraft Production as director of special projects he became closely associated with all British gas turbine work. In 1944 Dr. Roxbee Cox became chairman and managing director of Power Jets (Research and Development), Ltd., and when it became a Government establishment under the title of the National Gas Turbine Establishment he was appointed director. In 1940 he delivered the Wilbur Wright Memorial Lecture of the Royal Aeronautical Society, speaking on civil aviation, and in 1945 the Wright Brothers Memorial Lecture of the Institute of the Aeronautical Sciences on gas turbines. Last May he was honoured by the Universities of Brussels and Louvain and the Faculté Polytechnique de Hainaut at Mons. At Louvain Dr. Roxbee Cox was presented with the Memorial Medal of the University, and at Mons he was made an honorary member (of whom only five people have been so honoured) of the Association des Ingenieurs de la Faculté Polytechnique de Mons.

Emergency Committee of Atomic Scientists

"A NEW type of thinking is essential if man is to survive and move to higher levels." These words are quoted from a statement made last summer by Prof. Albert Einstein with which he designed to shock the world out of its complacency. Together with other prominent American men of science he expressed great concern at the use to which mankind would put atomic energy. He recognized that the problem, as Mr. Baruch has so wisely put it, is not one of physics but of ethics, and it is his belief that the only security and hope for mankind lies in a public educated to understand the simple facts concerning atomic energy and their implications for society, for an informed public will surely act for life and not for death.

A million dollars is needed for this great educational task. To collect this money, and to use it in an educational campaign to ensure that atomic energy will be used for the benefit of mankind and not for humanity's destruction, the Emergency Committee of Atomic Scientists, Incorporated, with headquarters at Princeton, New Jersey (Room 28, 90 Nassau Street), has been formed. The trustees are Albert Einstein (*chairman*), H. C. Urey (*vice-chairman*), H. A. Bethe, T. R. Hogness, P. M. Morse, L. Pauling, L. Szilard and V. F. Weisskopf. The Committee's programme, as outlined in communications recently received from Prof. Einstein, is to see that the following simple facts, which are accepted by all scientific workers, are given the widest possible publicity. They are: (1) that atomic bombs can now be made cheaply and in quantity, with future bombs likely to be even more powerful and destructive; (2) that there is no military defence against atomic bombs; (3) that other nations can discover for themselves the processes kept secret by the United States; (4) that preparedness against atomic warfare is futile and, if attempted, will ruin the structure of social order; (5) that if war does occur, atomic bombs will definitely be used, and will surely destroy our civilization; and (6) that international control of atomic energy and, ultimately, the elimination of war, is the only solution to the problem.

The Emergency Committee does not propose to make governmental policy, either at the national or international level, but intends to work through all appropriate educational organisations, including associations such as the Federation of American Scientists, into which, it will be recalled, most of the American organisations of scientific workers, which sprang into being spontaneously with the dropping of the atomic bomb on Hiroshima and the purpose of which was the study and promotion of atomic energy control, have since been united. The Federation, some time ago, set up a Committee for Foreign Correspondence (Box 615, Berkeley, California) to distribute literature on problems of atomic energy control throughout the world. With financial assistance recently received from the Einstein Emergency Committee, the Foreign Correspondence Committee has now been enabled to widen its activities very considerably. Letters, in a variety of languages, are being sent to scientific and social organisations, libraries, student groups, etc., and also to individuals in more than sixty different countries, in order to keep the public informed of developments in the United States; to develop an important medium for analysing mutual problems; to convince others of the sincerity of American men of science; and to create sufficient confidence, through friendly contact and understanding, to permit the operation of an international system of atomic control which is one of the keystones of the establishment of world peace.

Mutations Induced by Irradiation of the Substrate

W. S. STONE, O. Wyss and F. Haas (*Proc. U.S. Nat. Acad. Sci.*, **33**, 59; 1947) have discovered that mutations of *Staphylococcus aureus* may be induced by irradiating the medium with ultra-violet light before inoculation. Even a delay of 30 hours between irradiation and inoculation gave positive results. If the Fildes synthetic medium is irradiated, no growth takes place; this was later shown to result from toxic products of radiated glucose. Irradiation of the mineral salts of this medium gave no positive results, but irradiation of the vitamins and amino-acid fractions resulted in a marked increase of the mutation-rate. For example, penicillin-resistant mutants (in the irradiated series) ranged from six to a hundred times as many as in the controls; for resistance to streptomycin there was a similar increase of mutants. It was shown that these mutants were distinct and genetically controlled. Preliminary experiments indicate that it might be possible to induce an increase of a particular gene mutant without affecting others. The activation of the chemicals of the medium may be due to some mechanism involving a shift to a higher energy-level by the absorption of a quantum of energy during irradiation, or a definite change in the chemicals concerned. The substance created is called an 'activated mutator'.

Medical Libraries in the British Isles

MR. W. R. LE FANU's paper, "A List of Medical Libraries and Information Bureaux in the British Isles", in the *Journal of Documentation* of December 1946 is now available separately from the Association of Special Libraries and Information Bureaux (3*s*.). The list is based on a questionnaire issued by the Association in the autumn of 1944 to libraries known to possess medical collections and to hospitals, medical societies and medical institutions throughout the British Isles. Special libraries of pharmacy and veterinary medicine are included, but not those of anthropology or the biological sciences, except anatomy and physiology. Libraries and information bureaux are listed separately, the latter being institutions without libraries which have an active policy of gathering and disseminating information. The annotated lists are arranged alphabetically first for London, and then, separately, those outside London. A list of medical libraries holding periodicals registered in the World List and Union Catalogue is appended with an index of special collections and subjects.

Aerial Photographs for Scientific Purposes

From time to time aerial photographs are required for scientific purposes. Facilities for such photographs, required for non-commercial scientific purposes, may be provided by the Royal Air Force and Royal Navy, but such facilities are limited, and priority must, therefore, be allocated to the various requirements. The Advisory Committee on Airborne Research Facilities, a joint committee of the Royal Society and the Services, is to advise the Services on this matter. Requirements for photographs to be taken during 1948 should be forwarded to the Committee, at the Royal Society, Burlington House, London, W.1, before October 31, 1947; it will assist (*a*) if the envelope is marked 'Aerial Photographs'; (*b*) if grid references on the ordnance survey G.S.G.S. 1 in. series are quoted, alternatively exact latitude and longitude; and (*c*) if the scale required is stated. (It should be noted that cover is easier to provide in scales of 1/10,000 or 1/25,000.)

University of Birmingham: Appointments

The chair of production engineering established two years ago by a munificent gift from Messrs. Joseph Lucas, Ltd., has been filled by the appointment of Dr. T. U. Matthew, director of research of the Bedaux Company for Africa, Ltd. Dr. Matthew's exceptional ability, capacity for research, experience of the technical as well as the production and administrative sides of engineering, his wide interests and scholarly mind will enable him to fill the post with distinction and success. He had a brilliant career at King's College, London, and in post-graduate research at Cambridge. The chair of production engineering was established "to foster through research the full development of every aspect of Production Engineering and the education through special post-graduate courses of a supply of men who possess not only a sound grasp of the fundamentals of engineering but also a specialized knowledge of production methods and processes and the varied aspects of organisation and control".

The chair of zoology has been filled by the appointment of Mr. P. B. Medawar, lecturer in zoology in the University of Oxford and a fellow of Magdalen College.

Prof. V. G. Childe, professor of prehistoric European archæology in the University of London, has been appointed Mason Lecturer for 1947–48.

Commonwealth Fund Fellowships Awards

The Committee of Award of the Commonwealth Fund Fellowships has made the following appointments, among others, to fellowships tenable by British graduates in American universities for one year beginning September 1947: J. P. Bentley, Charing Cross Hospital Medical School and King's College, University of London, to Emory University, Atlanta, Georgia, in surgery; M. R. Bonham Carter, Balliol College, Oxford, to the University of Chicago, in political science; R. P. Brittain, University of Glasgow, to New York University College of Medicine, in forensic medicine; A. J. Y. Brown, University of Aberdeen, to the University of California, in economics; W. J. G. Cameron, College of Technology, Queen's University, Belfast, and Queen Mary College, University of London, to the University of Illinois, in engineering; F. J. Dyson, Trinity College, Cambridge, and Imperial College of Science and Technology, University of London, to Cornell University, in mathematics; F. H. Holmes, University of London, to Princeton University, in chemistry; Dr. James Innes, University of Edinburgh, to Washington University, St. Louis, in medicine; D. S. Jones, Corpus Christi College, Oxford, to the Massachusetts Institute of Technology, in mathematics; Dr. I. C. Jones, University of Liverpool, to Harvard University, in zoology; James Kenny, University of Glasgow, to Princeton University, in economics; Dr. G. A. Maw, University College, University of London, to Cornell University Medical School, in biochemistry; Bowman Scott, Imperial College of Science and Technology, University of London, to Harvard University School of Business Administration, in engineering; Alexander Slessor, University of Glasgow, to Harvard University Medical School, in medicine; Dr. Harry Stalker, University of Edinburgh, to Cornell University Medical School, in medicine.

The following have been appointed to fellowships tenable by candidates holding appointments in the Home Civil Service: T. F. Bird, Balliol College, Oxford, and London School of Economics, University of London, of the Ministry of Civil Aviation; C. E. Calveley, King's College, University of London, of the Post Office; J. A. R. Pimlott, Worcester College, Oxford, of the Lord President's Office; J. B. Williams, McGill University, and Trinity College, Cambridge, of the Colonial Office (fellowship awarded in 1939).

Announcements

At a Congregation at the University of Cambridge on June 12, eleven honorary degrees were conferred, including that of Sc.D. on: Prof. Linus C. Pauling, professor of chemistry in the Californian Institute of Technology; Sir Edward Mellanby, secretary of the Medical Research Council; Prof. C. T. R. Wilson, emeritus professor of natural philosophy in the University of Cambridge.

Prof. V. G. Childe, professor of prehistoric European archæology in the University of London, has been elected a member of the Royal Netherlands Academy of Sciences of Amsterdam (Section of Letters and Historical Sciences).

The Commissioners for the Exhibition of 1851 announce the award of senior studentships for 1947 to the following: On the recommendation of the University of Cambridge: J. S. Courtney-Pratt, for research in physics at the University of Cambridge. On the recommendation of the University of Oxford: D. H. Whiffen, for research in physical chemistry at the University of Oxford; E. M. Vaughan-Williams, for research in pharmacology at the University of Oxford. On the recommendation of the Imperial College of Science and Technology, London: Dr. K. D. Froome, for research in physics at the Imperial College of Science and Technology, London.

Aromatization of *cyclo*Hexane Carboxylate in Liver Slices

A FEW examples of the occurrence of aromatization of alicyclic compounds in the animal body are known, and similar reactions have been suggested in the formation of sex hormones and possibly carcinogens from sterols and bile acids[1]. Hitherto, however, the reaction has not been demonstrated in isolated tissues. The ready conversion of *cyclo*hexane carboxylic acid to benzoic acid by the dog, man and rabbit[2] suggested investigation of this transformation as a preliminary to the fuller study of aromatization in tissues. Rabbits of about 2·8 kgm. weight were first fed or injected subcutaneously with doses of 1·6–2·6 gm. sodium *cyclo*hexane carboxylate, of which about 0·9 gm. was isolated in the form of hippuric acid from the urine passed in the next 24 hours, thus confirming the work of Bernhard[2], and showing an adequate rate of aromatization. A method was evolved[3] for the micro-estimation of benzoic or hippuric acid in presence of *cyclo*hexane carboxylic acid, depending on cold nitration to the *m*-nitro derivative, reduction of the latter to the amino-compound, and estimation by diazotization and coupling with N-(1-naphthyl)-ethylene diamine.

FORMATION OF BENZOIC ACID FROM *cyclo*HEXANE CARBOXYLATE BY RABBIT TISSUES

	Q^* benzoic acid
Liver slices, O$_2$, phosphate	0·19
" " " " + HCN	0·04
" " N$_2$ "	0·01
" " O$_2$ + CO$_2$, bicarb.	0·26
" " " " + HCN	0·06
Liver homogenate, O$_2$, phosphate	0·04
Kidney slices " "	0·09
Skeletal muscle " "	0·004
Blood	0·025
Testis	0·00
Spleen	0·00

Liver slices in phosp., O$_2$, *cyclo*hexane carboxylate molarity as follows:

	0·10	0·05	0·025	0·01	0·004	0·001 *M*
Q_{benzoic}	0·03	0·08	0·11	0·16	0·19	0·22

* To convert Q_{benzoic} to μgm. benzoic acid/mgm. dry wt. tissue per hour, multiply by 122/22·4 = 5·44.

The extent of formation of benzoic (or hippuric) acid from added *cyclo*hexane carboxylate by rabbit tissues is shown in the accompanying table. This aerobic oxidation occurs mainly in liver and kidney, is inhibited by anaerobic conditions or in presence of cyanide, and by homogenization of the tissue. Derivatives of *cyclo*hexane carboxylate (hexahydrohippuric acid and hexahydrobenzamide) are also aromatized. The reaction appears to be complex, involving intact cell structure and iron-containing respiratory enzymes. Attempts to prepare a dehydrogenase have as yet been unsuccessful.

It is remarkable that the formation of benzoic acid is strongly and increasingly inhibited by *cyclo*hexane carboxylate, even by concentrations (above 0·001 *M*) which scarcely affect the total respiration (see table). This fact makes isolation of the product more difficult, and for this purpose two 45-gm. portions of a sliced rabbit liver (total weight 95 gm.) were suspended in 450 ml. bicarbonate – Ringer solution (*a*) without, (*b*) with *cyclo*hexane carboxylate, 0·0012 *M*. After shaking for 3 hours at 38° in oxygen plus 5 per cent carbon dioxide, the solutions contained, by analysis, (*a*) 0·30 mgm., (*b*) 33·6 mgm. benzoic acid, that is, 55 per cent conversion of the added *cyclo*hexane carboxylate. The 60 per cent ethanol extracts were concentrated *in vacuo*, treated with tungstic acid, and extracted with ether for 20 hours. Recrystallization from water of the ether concentrate of (*b*) yielded 26 mgm. hippuric acid, identified by m.p., mixed m.p., and by m.p. and analysis of the *p*-nitrobenzyl ester. The source and function of the glycine used for conjugation are being examined.

The occurrence of aromatization in liver slices at a rate comparable with that in the intact animal is thus demonstrated, and other examples of this biologically important reaction are now being sought.

Spectroscopic Estimation of Penicillin *G*

THE presence of a phenyl group enables penicillin *G* to be estimated in mixtures containing other penicillins of non-aromatic type. The spectra were photographed on Ilford Autofilter plates with a Hilger medium quartz spectrograph (*E* 498) using the continuous radiation from a hydrogen discharge lamp; an exposure of 30 sec. was needed with a slit width of approximately 0·05 mm. Under these conditions, phenyl absorption bands at 2685, 2645, 2585 and 2525 A. are observed with a solution of sodium penicillin *G* in a mixture (1 : 30) of water and ethanol having a concentration of 15 mgm./ml. at a path-length of 1·5 mm.

To compare the penicillin *G* contents of different samples of penicillin, the method of matching developed by Dr. W. C. Price[1] is used. The spectrum of the sample under investigation is photographed several times on a plate, using a series of path-lengths, which are varied by means of a Hilger micrometer cell or a wedge cell. Alongside each exposure is recorded the spectrum of a standard penicillin solution, using the same path-length each time. The path-length at which the spectrum of the unknown solution matches that of the standard is estimated by eye, interpolating between spectra when necessary. The relative concentrations of the two solutions are given by the inverse ratio of the path-lengths.

As an alternative to penicillin *G*, an alcoholic solution of phenyl acetamide (9 mgm./ml. at 1 mm. path-length) can be used as a sub-standard. Its spectrum is not identical with that of penicillin *G*, since the unspecific absorption of the penicillin molecule overlies some of the phenyl absorption bands, but matching is possible at 2685 A. and 2645 A. In penicillin *G*, these bands are displaced slightly (less than 3 A.) to shorter wave-lengths, and the displacement increases as more water is added to the solvent until, in water alone, it is about 12 A. and the bands are then very diffuse. The molar extinction coefficients of a reputedly pure sample of penicillin *G* and of phenyl acetamide were found to be the same at the matching wave-lengths. Recently, however, samples of sodium penicillin *G* have been prepared here that have an apparent purity of 104 per cent when compared in this way, and, clearly, the real penicillin *G* content of a sample cannot be determined until the spectrum of phenyl acetamide has been compared with that of pure sodium penicillin *G*. In the meantime, figures can be obtained which are in error only to the extent that the standard penicillin is impure.

If all the absorption at 2685 and 2645 A. were due only to penicillin *G*, a spectrophotometer could be used instead of matching. Unfortunately, in all but very pure samples of penicillin, the spectrum shows, in addition to the phenyl bands, a continuous absorption due to impurities, so that estimates from optical densities would be high. In the analysis of hydrocarbons, however, it has been found that, provided the additional unspecific absorption is not too strong, the pattern of a spectrum is not affected and can be used for matching. Similarly, we have found that the spectra of pale yellow samples of penicillin which give definite greying of the photographs can be matched against the spectrum of phenyl acetamide. The estimated error of the method is ± 2 per cent when the unspecific absorption is small; when it is large, matching is more difficult and results tend to be high.

With very yellow samples of penicillin, the method fails. In such instances, the samples can be oxidized with potassium permanganate solution at 100° C., the resulting suspension cleared with sulphur dioxide and an aliquot portion diluted with four times its volume of ethanol, filtered and matched as described above against a standard made by dissolving benzoic acid in ethanol and diluting with a quarter the volume of water. It was established by treating the purest available specimen that the oxidation of penicillin *G* to benzoic acid is quantitative. The presence of ethanol is essential, as the bands at 2810 and 2730 A., used for matching, do not appear in aqueous solution.

It should be emphasized that both these methods estimate all phenyl groups, including any that are present in deactivated products or impurities. With fairly pure samples, this does not appear to introduce serious errors; but with cruder preparations, results are correspondingly less reliable.

We are indebted to Dr. R. H. Hall for carrying out the oxidations, and to the directors of the Distillers Co., Ltd., for permission to publish this work.

Antibiotic Agents in the Substrates from Cultures of the Genus *Marasmius*

DURING current investigations into the production of antibiotic substances by Hymenomycetes, it was found that certain species of the genus *Marasmius* had a marked inhibiting effect upon growth of *Staphylococcus*.

In testing for antibiotic properties, the fungi were grown as surface felts on stationary shallow layers in Erlenmeyer flasks of 100 ml. capacity. The culture vessels used were made of special resistance glass; it had been found that the minute amounts of inorganic elements entering the nutrient solution from chemically resistant glassware of less satisfactory quality on sterilization in the autoclave were able to cause serious irregularities in the formation of antibacterial agents[1]. The synthetic nutrient media employed in the qualitative tests and in preliminary attempts to increase the yields of antibiotic substance contained, besides the usual mineral salts, glucose as the source of carbon and energy, and ammonium nitrate, ammonium chloride, or ammonium tartrate as the source of nitrogen. The media were supplemented with thiamin (1γ per 25 ml.), and, in some cases, with biotin ($0{\cdot}05\,\gamma$ per 25 ml.); these growth factors, added singly or together, being indispensable for normal growth of the fungus species tested[2]. The vitamin preparations used were thiamin hydrochloride Merck (Darmstadt) and biotin Merck (Rahway, N.J.). In some culture series the media contained small quantities of zinc, calcium and manganese added from dilute stock solutions of sulphates or chlorides, these minor elements being essential for, or promoting highly, the growth of species of *Marasmius*[2]. In other culture series the basal media were supplemented with 'Vitrum' malt extract or water extracts of aspen litter, the latter material containing organic and inorganic substances effective as growth-stimulating agents upon soil fungi of different biological groups[2-5]. The culture media were buffered to the respective optimum *p*H values by the addition of hydrochloric acid and solutions containing mixtures of mono- and dihydrogen phosphates. The nutrient solutions were sterilized by heating in the autoclave for 15 min. at a temperature of 120° C. or by passing through a Seitz filter. Each culture flask contained 25 ml. of the respective substrates.

The contents of the flasks were inoculated with square bits cut out from colonies of the fungi grown in Petri dishes on ordinary malt agar or on agar media made up with synthetic nutrient solution and malt extract. The area of each piece of inoculum was about 4 sq. mm. The cultures were incubated in the dark at a temperature of 25° C., great care being taken to keep the small pieces of inoculum floating on the surface of the substrate.

In order to gain information about possible relationships between growth of mycelium and formation of antibiotic substance, cultures of the different series were harvested at intervals of one or a few days, the fungal mats being weighed after thorough washing in distilled water and drying for 24 hr. at 100–102° C., and the substrates being tested for antibacterial activity against *Staphylococcus aureus* No. 266 by means of the cylinder plate method[1,6]. In addition, the hydrogen ion concentration of the substrates was determined electrometrically at all points of observation.

Both *Marasmius graminum* (Lib.) Berk. and Br. ap. Berk. and *M. ramealis* (Bull. ex Fr.) Fr. were found to be highly active producers of antibacterial agents on all the media tested. However, the formation of substances effective against *Staphylococcus* starts at different times on the different media. The duration and maximum level of antibiotic activity also vary considerably with composition of the medium. *M. foetidus* (Sow. ex Fr.) Fr. and *M. scorodonius* (Fr.) Fr. proved highly active against *Staphylococcus*. *M. alliaceus* (Jacq. ex Fr.) Fr., *M. androsaceus* (L. ex Fr.) Fr. and *M. rotula* (Scop. ex Fr.) Fr. were practically inactive under the conditions of the assay method used.

A more detailed account of the results of this investigation will be published in due course in Swedish journals of botany.

Use of Potassium in the Assay of Curare

Now that tubocurarine, one of the curare alkaloids, is gaining importance in medicine, it is important that this compound and other curare-like substances should be biologically standardized. A suitable method has been described by Chou[1], utilizing the rat's phrenic nerve-diaphragm preparation of Bulbring[2]; but we have been unable to obtain consistent results with this technique. By using temperatures lower than usual for mammalian tissue work (namely, room temperature, about 20° C.), we have obtained satisfactory results. The preparation lasts for a much longer period of time, shows little sign of fatigue after eight hours, and contractions are more regular. Larger doses of tubocurarine are needed than those used at 37° C., and a reduction in contraction of approximately 50 per cent is obtained with 0·15 mgm.

The difficulty with this technique is that the preparation requires a long time for complete recovery (more than 30 min.); but this has been overcome by the addition of small amounts of potassium ions to the bath during recovery phase, after the curare action has been shown for 3–5 min., according to the preparation. The anti-curare action of potassium is well known. When recovery is complete, the potassium is washed out and the next dose of curare-like substance is added (a total of 6–10 min. after the last dose). Potassium chloride itself exerts a stimulating action in this preparation in small doses (20–30 mgm.), whereas in larger doses (80–100 mgm.) the depressant effect predominates. These quantities refer to an isolated organ bath of 75 ml. capacity.

Leukotaxine and Histamine

Inflammatory exudates contain a polypeptide, leukotaxine, which has, among other properties, that of inducing increased capillary permeability on intracutaneous injection[1,2,3]. Other observations suggest that histamine may play a fundamental part in wheal formation of allergic and non-allergic origin[4–9]. It has therefore been suggested that the active factor in inflammatory exudates is really histamine and not leukotaxine, or that leukotaxine, if it exists, induces an increased permeability of the capillaries only through the mediation of histamine[8].

That leukotaxine is not histamine is suggested by the observations[1,2] that: (1) leukotaxine does not cause contraction of the isolated guinea pig ileum; (2) histamine is not chemotactic for leucocytes, but leukotaxine is; (3) intravenous injection of leukotaxine does not lower the blood pressure of the cat.

Moreover, crude preparations of leukotaxine, prepared by the method of Cullumbine and Rydon[2], when extracted for histamine (Barsoum and Gaddum's method[10]) and assayed on the isolated guinea pig ileum, yield insignificant quantities of histamine; for example, 6 mgm. (550 'units') of crude leukotaxine contained less than 2 μgm. of histamine.

We have used the anti-histamine substance 'Neoantergan', or 2786 R.P., which prevents or diminishes the action of histamine in increasing capillary permeability[11,12] in further studies on the mode of action of leukotaxine and the production of œdema following cutaneous burning.

We have observed that rabbits burned under nembutal anæsthesia, by exposing their depilated abdomens for 90 sec. to a glass vessel containing water at 70° C., develop extensive subcutaneous œdema of the abdominal wall within two to four hours of burning. The subcutaneous injection of 'Neoantergan' in a 10 mgm./kgm. dose (half the subcutaneous dose of this drug required to produce toxic symptoms in the rabbit) 30 min. before, or immediately after, or one hour or two hours after burning did not apparently affect the rate of development of the œdema or the degree of œdema produced by the burning.

Each burned area of skin yielded 30,000–60,000 'units' of leukotaxine. The intracutaneous injection of 60,000 'units' of leukotaxine into the abdominal wall of normal rabbits or rabbits medicated with 'Neoantergan' (10 mgm./kgm.) produced an œdema comparable to that induced by the burning.

If 1·25 c.c./kgm. of a 5 per cent solution of Pontamine Blue in 0·6 per cent saline is injected intravenously into a rabbit, and then a solution (0·2 c.c.) of leukotaxine or of histamine is injected intracutaneously into the depilated abdominal wall of the rabbit, blue areas rapidly develop at the sites of the cutaneous injections. 'Neoantergan' administered: (1) subcutaneously in a 10 mgm./kgm. dose and 30 min. before the test agents (0·2 c.c. of solutions containing 0·1 mgm. crude leukotaxine/c.c. or 0·1 mgm. histamine/c.c. respectively); or (2) intracutaneously (0·2 c.c. of a solution containing 40 mgm./c.c.) at the sites of injection of the test agents and immediately after the test agents; or (3) intracutaneously in a solution containing 40 mgm. 'Neoantergan'/c.c. and 0·1 mgm. crude leukotaxine/c.c. or 0·1 mgm. histamine/c.c., did not prevent the development or diminish the intensity of the blue staining at the sites of injection of the leukotaxine solution, but did completely prevent the blue staining at the sites of the histamine injection.

These observations suggest that the local liberation of histamine is not necessary for the production of subcutaneous œdema after cutaneous burning in the rabbit, and that leukotaxine does not induce an increased capillary permeability through the mediation of histamine. But the evidence is not conclusive, since the doses of 'Neoantergan' used, although large, may have been inadequate to deal with the amount of histamine that may have been liberated locally by the leukotaxine preparations. Higher concentrations of 'Neoantergan' cannot be used locally, since this drug itself, on intracutaneous injection in high concentration, produces a positive blue reaction and so may mask the leukotaxine reaction. This local irritant action of 'Neoantergan' suggests that histamine cannot take an intermediary role in the production of increased capillary permeability during the inflammatory reaction.

Serum Bilirubin and the Van Den Bergh Reaction

THE problem of the nature of direct and indirect bilirubin remains obscure, in spite of many attempts to explain the phenomenon of the two types of reaction. Some authors[1] still believe that direct bilirubin is free, and that indirect bilirubin is combined with serum protein, and alcohol converts one to the other, as does the liver, by an uncoupling action. However, this view seems no longer tenable since much evidence is available to show that both forms of bilirubin are combined with serum albumin[2-4]. The dual reaction is ascribed to the different strength of attachment of the pigment to the protein[5,6].

In our experiments no evidence was obtained supporting this view. The burden of the investigation is as follows:

(1) Addition of the most active promoting substances was without effect upon the attachment to protein, as deduced by dialysis and ultrafiltration experiments. Caffeine was exceptional in causing fission, although its effect in the van den Bergh reaction is more delayed.

(2) The final product, azobilirubin, was found to be combined with serum protein in every case. It is clear, therefore, that the behaviour of bilirubin is not to be explained by its liberation from protein attachment.

(3) Enzyme digestion of serum containing bilirubin or artificial bilirubin-protein compounds (prepared from serum albumin, serum globulin, globin or casein) by means of papain or pancreatin under optimum conditions caused no change of reaction. The reaction was indirect in each case, before and also following enzyme digestion, suggesting that neither the type of protein (cf. ref. 6) nor its size is a critical factor in the rate of production of azobilirubin.

(4) In addition to those substances known to change indirect to direct reacting bilirubin (ethanol, acetic acid, acetone, caffeine), we have found that pyridine exhibits this action in low concentration (5 per cent in serum) without precipitating the serum proteins or diluting the final colour. The introduction of pyridine in the van den Bergh test for bilirubin would bring many advantages.

(5) In a comparative study of the promoting effect of several alcohols, methanol, ethanol, propanol and isopropanol were equally active, higher alcohols less active, and glycerol and ethylene glycol gave negative results.

(6) No specific factor able to facilitate the van den Bergh reaction with bilirubin could be demonstrated or separated from direct sera, nor does there appear to be an inhibitor in indirect serum. Examination was made both of native serum and also following enzyme digestion to detach adsorbed substances from the protein.

(7) It is apparent that differences in the type of reaction must be ascribed to the pigment itself. The possibility arises that indirect bilirubin may be an intermediate precursor of bilirubin in hæmoglobin breakdown, still attached to globin, the precipitation reactions of which simulate those of serum albumin. This supposition has received experimental support, because direct-reacting serum when mildly oxidized with 0·3 per cent hydrogen peroxide under controlled conditions exhibits the characteristic behaviour of indirect serum bilirubin with the van den Bergh reagent and alcohol or pyridine.

Neutral Auxins

IN a previous paper[1], I have presented evidence that 3-indole acetaldehyde is a growth hormone in higher plants. Since this substance has not been prepared in the pure state, only indirect evidence that the auxin found is actually 3-indole acetaldehyde could be provided. Dr. K. A. Jensen, of the Chemical Laboratory, University of Copenhagen, has made a crude preparation of 3-indole acetaldehyde which I have tested. It proved to act in the same way as the neutral fraction of ether extracts of etiolated plants and as the crude preparations obtained by treatment of tryptophane with isatin or ninhydrin. The attempts to synthesize 3-indole acetaldehyde are being continued and will be reported elsewhere. In addition, an investigation on a series of other non-acid homologues of acid auxins has been started. Some of the results of this work are given below.

The accompanying table gives the relative activity of the compounds tested, based on the concentrations required for 5° curvature in the *Avena* test as carried out in this Laboratory, using soil-grown test plants. The values for 3-indole acetaldehyde are based on determinations obtained after the aldehyde had been converted to 3-indole acetic acid by treatment with soil[1]. The values have been corrected for a destruction of 50 per cent which is also caused by the soil in the procedure used (destruction was determined in experiments with the pure acid). These

Substance tested	Concentration required for 5°* curvature in the *Avena* test Mgm./l.	Relative activity	Maximum angle	
			Mgm./l.	Degrees*
3-Indole acetic acid	0·026	100	0·15	58
3-Indole acetaldehyde	0·125?	20 ?	0·20	20–50
3-Indole ethyl alcohol	250	0·01	450	8·5
α-Naphthalene acetic acid	0·09	29	2·7	30
α-Naphthalene acetaldehyde	48	0·05	120	14
Phenyl acetic acid	2500	0·001	10^4	8
Phenyl acetaldehyde	—	7×10^{-5}	3×10^4	6

* 5° curvature corresponds to a *d*-value of 0·10 (*d* is the difference in length between the inner and outer side of the curved coleoptile, measured in mm.).

values are, of course, uncertain; the relative activity may be between 10 and 40. 3-Indole ethyl alcohol (tryptophol) and α-naphthalene acetaldehyde were prepared by Dr. K. A. Jensen. These substances, as well as phenyl acetaldehyde, were freed from possible traces of acid substances by shaking ethereal solutions with alkaline water immediately before the test; phenyl acetaldehyde was redistilled before shaking. As 5° curvature is near the maximum angle produced by the latter substance, its relative activity was calculated on the basis of 3° curvature. In the table are also shown the maximum angles for the compounds tested and the concentration needed for maximum curvature.

Other workers (using water-cultured test plants) found the relative activities of alpha-naphthalene acetic acid and phenylacetic acid to be 2·5 and 0·02, respectively (compare Veldstra's list[2]). These values do not agree with those given here, obtained on soil-grown plants. This discrepancy may be due to the different methods of cultivating the test plants.

3-Indole acetaldehyde could be oxidized to 3-indoleacetic acid by treatment either with raw milk, with a purified Schardinger enzyme preparation (aldehydrase) or with soil. By soil treatment the activity of the aldehyde preparations was increased about 2·5 times. Soil treatment of indole ethyl alcohol and of alpha-naphthalene acetaldehyde preparations increased their activities by 100 and 20 times, respectively, indicating that these compounds are also oxidized by the soil, with the formation of the much more active acids.

Molecular Weight of Melanin

A METHOD of obtaining protein macro-molecules in crystalline form by the use of heparin has been described by Cohen[1]. As melanin is generally believed to have a high molecular weight, an attempt has been made to crystallize it by Cohen's method, using ethylene chlorhydrin as solvent. Heparin is not soluble to any appreciable extent in pure ethylene chlorhydrin; but both it and melanin are soluble in a mixture of equal parts of water and ethylene chlorhydrin. 'Dopa' and *Sepia* melanin have been used, with concentrations of heparin of 1, 2, 5, and 10 per cent, with and without addition of electrolyte (sodium chloride), at temperatures varying from –20° to 20° C. The attempt has failed completely, no precipitate being observed under any conditions even after standing for seven days.

It was observed by Cohen that although a number of highly complex proteins were precipitated by this method, those of comparatively low molecular weight, for example, gelatin, edestin and pepsin, did not respond, even with concentrations of heparin up to 10 per cent. This suggests, though by no means proves, that the molecule of melanin may not be so large as has been supposed. Further work at present in progress tends to support this view.

The work has been carried out with the aid of a grant from the Government Grant Committee of the Royal Society.

Free Radicals from Benzyl Hyponitrite

WE have recently prepared benzyl hyponitrite by the method of Partington and Shah[1], and have found that it readily catalyses the polymerization of methyl methacrylate at room temperatures. At 30° C. the rate of polymerization of methyl methacrylate initiated with benzyl hyponitrite is approximately thirty times as fast as the rate observed with an equal amount of benzoyl peroxide.

The polymerization of this monomer is known to be initiated by free radicals, and the benzyl hyponitrite must therefore produce free radicals by decomposition. By analogy with other compounds containing the —N=N— group which are sources of free radicals, it is probable that benzyl hyponitrite decomposes into two benzoxy radicals $C_6H_5CH_2O$— with the elimination of nitrogen. The formation of benzaldehyde and benzyl alcohol in presence of water reported by Partington and Shah could then be due to disproportionation of these benzoxy radicals.

Addition of Dinitro Compounds to D.D.T. to Prevent Outbreak of Spider Mites

IT is frequently observed that the use of sprays containing D.D.T. on fruit trees leads to a severe outbreak of Tetranychid mites or red spiders. In the United States, for example, *Tetranychus pacificus* McG., *Paratetranychus pilosus* C. & F. and *P. citri* McG. have all been found to increase very considerably after D.D.T.-spraying has killed the predaceous insects which normally keep them under control. Research workers who have obtained excellent control of codling moth (*Cydia pomonella* L.) or other pests with D.D.T. have felt unable to recommend its general use owing to the risk of producing a severe mite infestation. It may therefore be of interest to record a method by which this difficulty was overcome by the addition of dinitro-*ortho*-*cyclo*hexylphenol to the spray. The successful use of this material in the United States has been recorded, but does not appear to be widely known even there; and it has never previously been tested on *Bryobia* mite, the prevailing 'red spider' of South African and Australian fruit crops.

Spraying trials against codling moth were carried out in South Africa during the 1946–47 season at Elgin, Cape Province, in collaboration with the Western Province Fruit Research Station, Stellenbosch. Two D.D.T. preparations were used, a xylene emulsion and a dispersible powder, both diluted to give 0·1 per cent actual D.D.T. The remainder of the orchard received the standard treatment with a proprietary nicotine–bentonite preparation. By the end of December, after five sprays, a heavy outbreak of *Bryobia prœtiosa* Koch was evident on the D.D.T.-sprayed trees, but there were very few on those which received nicotine. After this time, owing to shortage of supplies, it was unfortunately necessary to use a proprietary fixed nicotine containing 0·05 per cent D.D.T., and the red spiders then began to increase also on these plots. On January 8 and 19 and February 9, 1947, half of each plot was sprayed with D.D.T. containing dinitro-*ortho*-*cyclo*hexylphenol in the form of its di*cyclo*hexylamine salt at 0·00625 per cent. A sample of the red spider population taken on February 17 gave the result shown in the following table, in which the figures for the active and 'resting' stages are combined.

Summer spray schedule	Total spiders per 16 leaves	
	Without dinitro compound	With dinitro compound in 3 sprays
D.D.T. (0·1%) emulsion, 9 sprays	644	32
D.D.T. (0·1%) dispersible powder, 9 sprays	768	26
Fixed nicotine (0·05%) in first 4 sprays and fixed nicotine (0·025%) + 0·05% D.D.T. in last 5 sprays	246	175

The protection against *Bryobia* mite afforded by the addition of dinitro-*ortho*-*cyclo*hexylphenol, used even after an outbreak had started, is evident from the above figures. The dinitro compound is not so effective when used with fixed nicotine, presumably owing to formation of a nicotine salt of dinitro-*ortho*-*cyclo*hexylphenol, which is less toxic than the di*cyclo*hexylamine salt, or to adsorption on the bentonite. This point is being further investigated.

Autoxidation of Olefins: Formation of Unsaturated Alcohols from Olefins by the Action of Organic Peracids

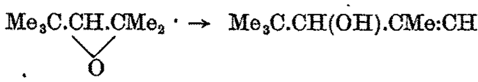
IT was reported in a previous communication[1] that peracetic acid reacts with α- and β-di*iso*butylenes to give an unsaturated alcohol and high-boiling material of the molecular formula $C_{16}H_{32}O_3$ in addition to the expected glycol. Thus β-di*iso*butylene (I) yields the unsaturated alcohol (II) with alteration in the position of the double bond; α-di*iso*butylene (III) gives rise to the two unsaturated alcohols (IV) and (V).

$Me_3C.CH{:}CMe_2$ (I) $Me_3C.CH(OH).CMe{:}CH_2$ (II)

$Me_3C.CH.CMe{:}CH_2$ (III) $Me_3C{:}CH{:}CMe.CH_2(OH)$ (IV)
$Me_3C{:}CH_2.C(CH_2OH){:}CH_2$ (V)

It is now found that the formation of these unsaturated alcohols does not depend on substitution of the olefin, but on the isomerization of the epoxide which is an intermediate in the reaction.

Thus 2 : 4 : 4-trimethylpentan-2 : 3-epoxide (VI) on treatment with acetic acid containing a trace of sulphuric acid gives 2 : 4 : 4-trimethylpenten-1-ol-3 (VII), the mono-acetate of 2 : 4 : 4-trimethylpentan-2 : 3-diol, and a high boiling liquid which is provisionally formulated as a tetramethyl di-*tert*.-butyl 1 : 4-dioxane. These are the main products of the reaction; but there is also formed an aldehyde which is presumably 2 : 2 : 3 : 3-tetramethylbutanal. The yield of unsaturated alcohol in this reaction is approximately equal to that of the glycol; that of the dioxane is rather less, while the aldehyde is only a minor product.



$Me_3C.CH.CMe_2$ (with O bridging, VI) → $Me_3C.CH(OH).CMe{:}CH_2$

(VI) (VII)

A change in the position of the double bond during the peroxidation of an olefin by molecular oxygen is said to occur[2-4], and it has been suggested[5,6] that the preliminary phase is the formation of a moloxide by saturation of the double bond by a molecule of oxygen. The hydroperoxide would then result by opening of the moloxide ring and change in position of the double bond.

The work described above now provides experimental support for this hypothesis by the demonstration that a similar system, namely, the epoxide ring, can behave in the manner postulated. Further, it suggests, if the analogy between the two types of oxygenated ring systems may be maintained, that the opening of the ring system may be accompanied by the formation of bimolecular oxygenated compounds and also carbonyl compounds. Such compounds are always formed during the peroxidation of olefins[7,8], and it might well be that they are formed at the same time as the hydroperoxide.

Further evidence that the double bond of the olefin is the initial point of attack during peroxidation is the presence of an epoxide among the products of air oxidation[8,9]. Although it is possible to explain these observations by assuming that the epoxide arises by a reaction of the hydroperoxide with the olefin, it may equally well arise from the moloxide by a side reaction.

The Meson Spectrum Near Sea-Level

L. Jánossy and J. C. Wilson determined, some time ago[1], from a comparison of theoretical and experimental spectra at sea-level the exponent γ in the production spectrum of mesons $dN = \text{const. } p^{-\gamma}dp$; they find a value $\gamma = 3\cdot3$. As this value differs appreciably from the ordinarily accepted one, we have thought it worth while to check the above result by a more accurate method, taking account of the variable energy-loss of mesons through the atmosphere.

The basis of our computation is a formula for the vertical meson spectrum at sea-level derived by M. E. Rose[2] with the hypothesis of an initial $\varepsilon^{-\gamma}$ spectrum. This formula is

$$f(\varepsilon,t_s)d\varepsilon = C_0 \frac{B(\varepsilon')}{B(\varepsilon)} \varepsilon'^{-\gamma} \exp{(-\alpha D)}d\varepsilon,$$

where ε' is the energy at the production level of a meson having energy ε at sea-level; $B(\varepsilon)$ is the energy loss $-\frac{d\varepsilon}{dt}$ (t in gm./cm.^{2}); $\alpha = \frac{t_s}{\rho_s c \tau_0}$ (with t_s height of the atmosphere in gm./cm.^{2}, ρ_s air density at sea-level, $c = 3 \times 10^{10}$ cm./sec., and τ_0 mean life of the meson at rest); D is the integral $\int_{R_s}^{R_0} \frac{dR}{tp(R)}$, with R_0, R_s residual ranges (in gm./cm.^{2}), of mesons of energies ε' and ε (p momentum of the meson).

Rose's expression is quite different from that given by Euler and Heisenberg[3], owing to a different treatment of the absorption of mesons. However, it is easily verified that it satisfies the following differential equation:

$$\frac{\partial f}{\partial t} = B(\varepsilon)\frac{\partial f}{\partial \varepsilon} + f\frac{dB(\varepsilon)}{d\varepsilon} - f\frac{\alpha}{pt},$$

where $f(\varepsilon,t)$ is the differential energy spectrum at level t. This equation is the generalization of that of Euler and Heisenberg to the case of variable energy loss (and energy- instead of momentum-distribution).

Assuming an initial spectrum $p^{-\gamma}$, instead of $\varepsilon^{-\gamma}$, Rose's formula becomes

$$dN = C\frac{B(\varepsilon')}{B(\varepsilon)}(\varepsilon'^2 + 2\varepsilon')^{-(\gamma+1)/2}(\varepsilon + 1)\exp{(-\alpha D)}\,d\varepsilon.$$

(Energy unit $= \mu c^2 = \sim 10^8$ eV.)

We have used this formula. It contains three parameters to be adjusted from experimental data: the normalization factor C, the exponent γ and α (corresponding to the mean life τ_0 of the meson). Each of these parameters appears linearly in the expression of log $dN/d\varepsilon$, making it relatively easy to apply a least squares method to log $dN/d\varepsilon$ and determine the parameters simultaneously.

The experimental data were those used by Jánossy and Wilson, namely, those of Blackett, Jones and Wilson, with the exclusion of the doubtful value near $\varepsilon = 1\cdot5 \times 10^{10}$ eV. To avoid giving a greater statistical weight to the high-energy region owing to the greater number of determinations, we averaged the experimental data, taking as experimental spectrum (normalized to maximum value 1):

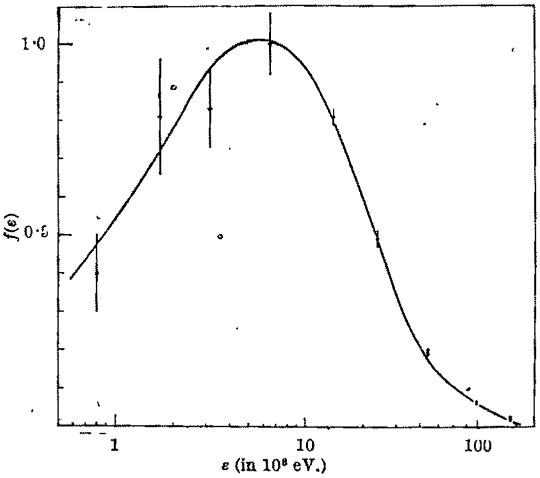
ε	$\frac{dN}{d\varepsilon}$	ε	$\frac{dN}{d\varepsilon}$
0·8	0·40	14·03	0·81
1·69	0·81	24·02	0·49
3·13	0·83	44·01	0·195
6·57	1·00	79·0	0·061

Application of the least squares method gives

$$\gamma = 3\cdot20,\ \tau_0 = 1\cdot69 \times 10^{-6}\text{ sec.},\ C = 2\cdot67 \times 10^5.$$

This seems to confirm that γ has a value somewhat higher than that usually accepted. The value of τ_0 seems rather small in comparison with the best experimental data, and it would have been even smaller had we used an initial $\varepsilon^{-\gamma}$ spectrum. It would be difficult, however, to draw any inference from this fact, owing to the uncertainty which still exists in the low-energy part of the spectrum.

The effect of a departure θ of the measured meson tracks from the vertical direction was also considered, but it was found that with a distribution of the form const. (l cos $\theta - r$ sin θ) valid for parallel counters of length l cm., placed r cm. apart from one another, no important errors should occur up to a maximum value of 30° for θ, which appears to be a reasonable upper limit.



The graph shows the accord between experimental data and theoretical curve.

Diffuse Bands on Laue Photographs of Silver Chloride Crystals

In a recent paper and in a communication in *Nature*[1], Laue photographs of large silver chloride crystals were published, showing diffuse bands and spots. It was then suggested that these bands were, at least partly, not of thermal origin, but due to the presence of definite lattice defects, parallel to the cubic planes and axes. The experimental fact that such crystals, when irradiated with ultra-violet light, showed an 'optical etching effect' parallel to the cubic planes (as evident from the reflexion of incident light by the irradiated crystals, which was similar to that shown by chemically etched crystals) was considered to support this conclusion. Moreover, on a photograph of a crystal cooled with liquid air, taken at the time the above paper was published, the diffuse pattern was still visible.

In view of the fact that in practically all other cases of diffuse bands published so far[2] they are temperature-dependent, it was worth while to make such photographs anew, now conditions for obtaining liquid air are again more favourable. These photographs show clearly that with silver chloride also the bands are of thermal nature, as they disappear practically completely at low temperatures. The apparently opposite effect obtained in the former experiment was probably due to insufficient cooling of the crystals. Diffuse bands due to lattice distortions of the type discussed in our note are thus, so far as known to us, not observed with certainty in any case[3]. The remarkable etching effect shown by the irradiated crystals remains, however, an indication that actually deviations parallel to cube planes are present in the crystals.

X-Ray Diffraction Studies of Yielding in Mild Steel

THE distribution of plastic deformation in a cold-stretched mild steel bar has been studied by X-ray diffraction methods. Using the back-reflexion technique with cobalt radiation, two spotty rings were obtained by reflexion of the $K\alpha$ doublet from the (310) plane of iron. Plastic deformation in the specimen was indicated by a blurring of the spots of the diffraction pattern as the individual crystals, which gave the reflexions, became distorted. An X-ray beam of about 1 mm. diameter was used to explore the distribution of the deformation.

A normalized, 0·26 per cent carbon steel bar was stretched in a tensile testing machine until the so-called 'Lüders lines' or 'Hartmann bands' appeared over part of its length. These Lüders lines are parallel strain bands, inclined at approximately 45° to the bar axis, and made visible by the flaking-off, along the bands, of the oxide scale produced by the normalizing process. The average plastic extension within the region showing Lüders lines was found from gauge marks to be about 1·5 per cent.

Fig. 1 represents a section of the bar including part of a region of strain markings. Figs. 2 *a–d* show portions of X-ray patterns obtained from the particular areas of the bar indicated in Fig. 1. In each case the chosen area was first etched with nitric acid to remove the oxide layer.

The pattern, Fig. 2 *a*, was obtained from an area within a region showing no strain markings. The sharpness of all but a few of the spots indicates that only slight plastic deformation occurred in this region. In the pattern, Fig. 2 *b*, obtained by directing the X-ray beam on a Lüders line (that is, on a band from which scale had peeled) almost all spots are diffuse, indicating marked plastic deformation.

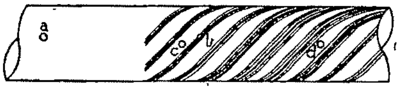

Fig. 1. PORTION OF A STRETCHED STEEL BAR, SHOWING PART OF A REGION OF LÜDERS LINES

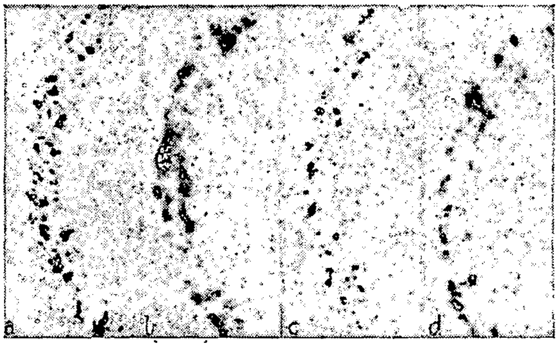

Fig. 2. X-RAY DIFFRACTION RINGS OBTAINED BY BACK-REFLEXION FROM POINTS *a*, *b*, *c*, *d* OF FIG. 1

Figs. 2 *c* and *d* illustrate patterns obtained from areas lying between two Lüders lines. For such areas chosen near the boundary of a region showing the strain bands, only a few of the spot reflexions are blurred, as in Fig. 2 *c*. However, in patterns such as Fig. 2 *d*, from such areas chosen near the centre of a region of Lüders lines, a greater proportion of the spots are blurred, although the blurring is still less extensive than in Fig. 2 *b*.

Since the region of Lüders lines grows as a bar is stretched, these results show that the amount of plastic deformation is much greater between Lüders lines formed at an early stage of the stretching than between those formed later, and is very slight between the most recently formed lines. These observations lead to a picture of the mode of yielding in mild steel similar to that proposed by Jevons[1]. At first a narrow band of material at about 45° to the axis of the bar undergoes plastic strain of the order of 2 per cent. With increased stress, other such bands, separated by regions of very little deformation, appear at successive intervals along the bar. As the region of strain-bands grows by the formation of new bands, the earlier formed lines grow laterally by an increase in plastic distortion on either side. Thus the distribution of plastic deformation becomes more uniform, and eventually the whole bar undergoes plastic strain of the order of 2 per cent.

The variation of deformation across a set of Lüders lines may be demonstrated readily by the use of an X-ray beam diverging from a point source through a long slit. A strip of the specimen at right-angles to the lines is irradiated, and gives diffraction rings broadened along their diameter parallel to the strip. Across the broadened portion of the rings, the spots are alternately sharp and diffuse, corresponding to the alternation of plastically deformed and underformed regions along the irradiated strip. Good resolution may be obtained by a suitable choice of radiation.

Recrystallization of Duplex Brass

ALTHOUGH the deformation and subsequent recrystallization of pure metals and single-phase alloys has been widely studied, little work has been done on the deformation of duplex alloys, that is, alloys containing two phases, and we know of no published work on their behaviour on annealing after cold work. The two phases will normally possess quite different physical properties. On application of a stress, the phase with the lower elastic limit will be plastically deformed at a lower stress, and the distribution of the deformation in the two phases will depend on their relative elastic limits and work-hardening characteristics. Recrystallization in the two phases can be expected to occur after different total deformations and at different temperatures, not only because of their different chemical compositions, but also because of the different extents to which deformation occurs in the crystals of the two phases.

The progress of recrystallization was studied in a duplex brass (60 per cent copper, 40 per cent zinc), the most familiar example of an alloy containing two deformable phases. The recrystallization was followed in two ways, namely, by the metallographic technique of electrolytic polishing, etching and microscopic examination, and by an X-ray diffraction method. From the character of the lines of the two phases which appear on the one diagram, the state of deformation or recrystallization can be assessed (see Fig. 1). Figs. 2 and 3 are photomicrographs which illustrate how recrystallization of the two phases can be distinguished metallographically. In all experiments there was a good agreement between the results obtained by microscopic examination and by the X-ray method.

A series of specimens was prepared from the gauge lengths of tensile specimens which had been strained by different amounts and then annealed. Some of the results obtained are summarized in the accompanying table. It is clear that the α-phase tends to recrystallize at lower temperatures and at lower deformations than the β-phase. This is to be expected, because the α-phase is softer and more readily deformed than the β-phase.

RECRYSTALLIZATION IN THE PHASES OF DUPLEX BRASS

% Elongation	Phases	State of recrystallization after annealing at			
		400° C.	425° C.	450° C.	500° C.

24	α	partly	partly	fully	fully
	β	none	none	partly	fully
18	α	none	just comm.	commenced	—
	β	none	none	none	

To determine the effect of the relative quantities of the two phases on recrystallization, specimens of brass wire (40 per cent zinc) were quenched from 750°, 650° and 550° C. respectively, thus producing alloys containing approximately 80, 50 and 30 per cent of the β-phase. Wire-drawing was employed as a means of deformation, since a greater amount of deformation could be imposed on the alloy than in a tensile test. The wires were cold drawn from 0·186 in. to 0·073 in. (85 per cent reduction in area), and specimens annealed at 300°, 350°, 400° and 450° C. for half an hour. There was a general tendency for the β-phase to recrystallize to a larger extent in the alloy containing the least quantity of the β-phase. For example, on annealing at 400° C., the β-phase in the 80 per cent β-alloy had just commenced to recrystallize; it was partly recrystallized in the 50 per cent alloy; and fully recrystallized in the 30 per cent alloy. A β-crystal will take part in the deformation to a larger extent when it is embedded in a matrix of soft α-crystals than when it has many hard β-crystals as neighbours. Consequently recrystallization will take place at lower temperatures in the former case.

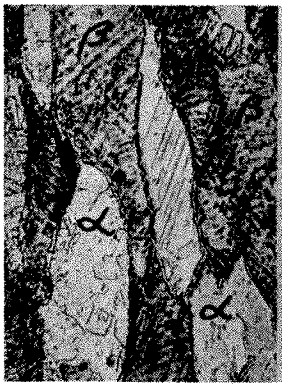

Fig. 2

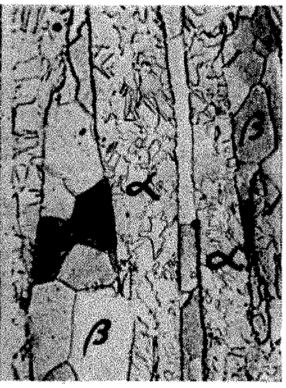

Fig. 3

Fig. 2. SPECIMEN IN WHICH THE α-PHASE IS PARTLY RECRYSTALLIZED; THE β-PHASE IS STILL DEFORMED

Fig. 3. SPECIMEN IN WHICH BOTH PHASES HAVE FULLY RECRYSTALLIZED

Photomicrographs × c. 400

In all the experiments described above, the crystals of the α-phase recrystallized before those of the β-phase. However, the β-phase commenced to recrystallize *before* the α-phase in a series of experiments where the original wire was air-cooled from 800° C., drawn to 85 per cent reduction in area and specimens annealed in the usual way. At 250° C. the β-phase had partly recrystallized, whereas the α-phase was still deformed. The composition and the relative proportions of the two phases were similar to those in alloys used previously. The only difference between this series and the other series was that these alloys had been *air-cooled* from 800° C., whereas the other alloys had been *water-quenched*. This suggested that a change in properties as a result of the order-disorder transformation might be responsible for the reversal in the sequence of nucleation.

To test this theory, two pieces of brass wire were annealed at 800° C., then slowly cooled. The first specimen was water-quenched from 475° C. (that is, just above the critical temperature of the order-disorder transformation), while the other was quenched from 400° C. (just below the critical temperature). Both wires were then drawn as in the other experiments, and specimens were annealed. X-ray and microscopic examination revealed that, in the wire quenched from *below* the critical temperature, the β-phase had partly recrystallized at 250° C., while the α-phase was still completely deformed. In the other wire, the α-phase commenced to recrystallize at 275° C., whereas the β-phase did not start to recrystallize until 300° C.

Thus the behaviour of duplex brass on annealing after deformation is quite complex. Order-disorder transformations do not, of course, occur in all alloys, but the effect of the relative proportions of the two phases is of general application. It is also evident that consideration must be given to the slope of the phase boundaries, for changes in composition of a phase will have some influence on its behaviour during recrystallization.

The Harmonic Cord

While the possibility of vibrating a thin cord regularly in a flat plane from a tuning fork has long been known as the 'Meldé cord', from its discoverer; and the development of large cigar-shaped loops on a thick stretched cord, corresponding to the fundamental and harmonic frequencies, by variable-speed electric-motor drive adjusted to the natural periods of the cord, has followed as a physical laboratory demonstration; it is not generally realized that a multiplicity of frequencies may be simultaneously developed on the same cord, by suitably designed mechanisms.

When two or more rotary vibrations having harmonic relations are superposed, stable figures may be produced alike for concurrent or opposed rotations, often very beautiful in form. The section at any position on the cord, which may be called the 'orbit' at that position, will be a trochoidal figure, twin or multiple elliptic if elliptic instead of circular rotations are imposed. The complete enclosing figure, which may be called the 'envelope', may have internal or external 'cells', corresponding to the internal or external loops of concurrent or opposed rotation trochoidal curves developed with the harmonic relationships chosen.

If two rotations which are not perfectly tuned to a harmonic relation are superposed, the whole envelope will rotate slowly for a small tuning error, and rapidly for a large one; while the evolution of form as a second vibration is impressed on an existing fundamental or harmonic vibration envelope is very fascinating to watch.

Where two rotations in the same direction and with nearly related frequencies such as 9 : 10 are superposed, the cord appears to pulse rapidly longitudinally as the addition and subtraction of amplitudes alternately occur; sometimes apparently similar effects may be noted temporarily while tuning other frequencies together.

A high harmonic of small amplitudes may be superposed on large fundamental or low harmonic cigar-shaped envelopes, and may produce a remarkable ripple effect on these surfaces, probably rotating over them.

With elliptic rotations there appears to be a pronounced tendency towards circularity, apparently by transference of energy between the two octave-related vibrations involved, as is readily seen when an elliptic drive is given to the cord. However, an interesting elliptic case is a circular drive at a considerable angle to the axis of the cord, so superposing a longitudinal wave on the transverse wave in a circular envelope system, and in effect producing an elliptic rotation; this produces an envelope which contains various octave orbits (but not accurately in planes normal to the cord axis) which may rotate slowly and show interesting cell and phase changes as it does so.

If rectilinear vibrations in different planes are impressed on the cord, the orbits are Lissajous figures; the cells and envelope forms evolving with change of phase relationships if the tuning is imperfect, no rotation of the envelope occurring in this case.

Up to the present, no facilities for the difficult photography of this figuring have been available; and sketching does not adequately or accurately record the complex and transparent forms which can be seen. It may be noted that musical instrument strings show similar orbits on a microscopic scale, as was first demonstrated by me in 1911, but with the figuring so slim that the beauty of the envelope forms could not be appreciated.

Mortality Required to Prevent Population Increase

Biologists have often calculated the vast numbers which would be reached in a relatively short period by the descendants of a single pair of insects or other fecund animals if all of them reproduced at the normal rate before dying. Such calculations are used to illustrate the high potential rates of population increase, or the severity of the natural checks to increase, or to show the very high mortality required to keep a fecund population within normal limits. It should, of course, be recognized that, in many cases, reductions in the rates of reproduction and development also play an important part in limiting increase. However, the purpose of this note is to direct attention to the fact that, in certain calculations of the 'necessary mortality', there is a striking fallacy.

An example may be taken from a paper by Payne[1] on the ecology of *Microbracon hebetor* Say and its host, *Ephestia kühniella* Zeller. The latter has "a total period from egg-laying to egg-laying of 62 days at 32° C., with 52·5 % of the adults females, and the number of eggs per female 181. The offspring from one female at the end of a year is 30,428,590,122 counting five generations to a year. The percentage that must die to keep the number constant is 99·99999999993." The astronomical size of these figures is due to the assumption that there is no mortality of offspring before reproduction, until the fifth generation, an unlikely event with most animals and certainly unrealistic in the case of *Ephestia*. If we make the more natural assumption that the mortality is the same in each generation, the surplus offspring per female in each generation is approximately 179, or 179 × 5 = 895 in five generations; to eliminate this surplus a mortality of less than 99 per cent in each generation is sufficient.

The origin of the misconception is apparently in a method developed by Bremer[2]. Considering an insect population of n individuals, of which a constant proportion n/b are females, each of which lays a eggs and then dies, Bremer expressed the proportion of the offspring that must be destroyed, in order to keep the number down to n, as $na/b - n$, or $n\,(a/b - 1)$. He called $a/b - 1$ the "normal coefficient of destruction", that is, the necessary mortality of offspring as a multiple of n. He also expressed this necessary mortality as a proportion of the number of offspring, calling this value the "normal destruction quotient", which is $n\,(a/b - 1)/na/b = 1 - b/a$. This is correct. Bremer then expressed the "normal coefficient of destruction" for a year, in which there are c generations, as $a^c/b^c - 1$, and the corresponding "normal destruction quotient" as

$$q_c = 1 - b^c/a^c. \qquad (1)$$

Both these formulæ imply that there is no mortality (except the death of adults after reproducing) for c generations.

Bremer's formula (1), and his correspondingly fallacious numerical example, were quoted by Blunck[3], and from him by Uvarov[4]. Both these authors called q_c the *coefficient* of destruction. Payne[1] also followed Blunck in confusing the coefficient and the quotient; moreover, the formula (1) is misquoted in her paper, but clearly she did not use it in that form.

Since the above error occurs in papers of some importance to insect population studies, it is desirable that it should be pointed out. If the method is to be used for periods embracing more than one generation, it is best to assume the same rate of mortality in each generation. Then the 'coefficient' will be $a/b - 1$ and the 'quotient' will be $1 - b/a$, whether one or many generations are involved. When such regular mortality cannot be assumed, the method is applicable only to single generations.

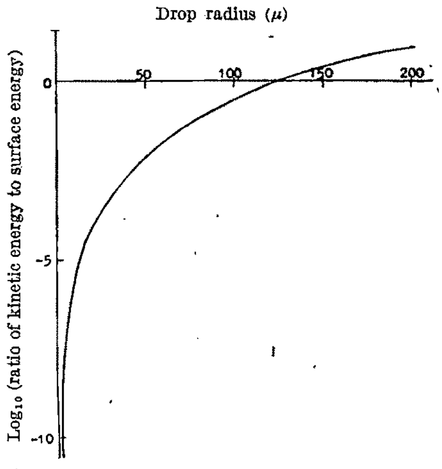
Collisions of Cloud Droplets

WHETHER cloud droplets coalesce on impact is a problem of obvious theoretical and practical interest, having bearings on theories of rain formation, methods of fog dispersal, the stability of clouds, etc. A major obstacle in the way of providing an answer to this question is the difficulty of simulating in the laboratory the conditions that obtain naturally in clouds. Nevertheless, in July 1941, I made some experiments in connexion with this subject at the Imperial College with the aid of facilities kindly provided by Prof. (now Sir George) Thomson, and with the help of Dr. J. Mazur, and the results obtained may be of interest to others concerned with the same problem.

The liquids used were pure water, fluess oil, absolute alcohol, α-chloro-naphthalene and benzene, these liquids being chosen for their widely differing physical properties. The drops were produced by spraying from an atomizer, and their behaviour in a small draught-proof chamber was observed through a microscope by light reflected from their surfaces. The outstanding result of the experiments was that droplets were never seen to coalesce on impact, neither when there were 'head-on' collisions nor when the drops, which were found to carry both kinds of electric charge (presumably due to their method of production), were made to collide more violently by applying an electric field. In all, the behaviour of many hundreds of droplets of each liquid was observed. Unfortunately, the apparatus limited careful observation to drops up to 2 μ radius, and this is less than the size that occurs most frequently in clouds. However, if the following explanation of the non-coalescence of these minute drops is correct, it may be inferred that cloud droplets may not coalesce on impact until they are much larger than this—probably greater than 50 μ radius, which is the size of drizzle drops.

Two small drops will separately assume the shape of minimum surface energy, a sphere. If they coalesce, the joint drop will again be a sphere in which the surface energy has a new and lesser minimum. During amalgamation, the drops will be distorted, and, though the mechanics of coalescence are not known, the distortion may cause an increase in surface energy. Such an increase of surface energy, though it would be small compared with the total, would constitute a barrier to coalescence: if it is overcome, the drops will amalgamate; if not, they will rebound. In this experiment the only mechanical energy available to overcome such a barrier was the kinetic energy of the drops, due either to fall under gravity or the electric field, and, unless this energy is comparable with the possible increase in surface energy due to distortion, amalgamation cannot take place. The graph shows how, for a water drop, the ratio of the kinetic energy at terminal velocity to surface energy varies with the drop size.

It is clear that the kinetic energy is quite insignificant for very small drops, and even at 50 μ radius the ratio is only 0·01. It is true that collisions between drops of different sizes are more likely than between drops of the same size; but in such cases the kinetic energy destroyed on impact will be much nearer that of the smaller drop. Hence, small as it is in comparison with the surface energy of the latter, it will be even more insignificant compared with that of



RATIO OF KINETIC ENERGY AT TERMINAL VELOCITY TO SURFACE ENERGY AS A FUNCTION OF SIZE OF DROP the larger drop, and coalescence is unlikely both for impact of small drops and for large drops with small ones. In this connexion it is of interest to record that when a large drop was formed in the experiments, it plunged through the chamber scattering the smaller ones in its path.

Silver Chloride Plates for Infra-Red Spectroscopy

ALTHOUGH rock salt has been commonly used in the construction of absorption cells for infra-red spectroscopy, it has the inherent disadvantages of being opaque beyond $15\ \mu$, and of being attacked by water. Silver chloride, however, is transparent up to $25\ \mu$ and is completely resistant to water.

Fugassi and McKinney[1] have briefly described a method for making silver chloride plates by rolling the fused material. Difficulties were encountered in rolling and casting when trying to repeat this work. Silver chloride plates of suitable quality, however, were prepared in this laboratory by the following method.

All operations were carried out in a darkened room lit by a 40-watt bulb. Silver chloride was precipitated from silver nitrate and sodium chloride, taking care that as little silver nitrate as possible was occluded in the precipitate. The latter was filtered off and dried at 105° C. A piece of porous porcelain (2 in. × 2 in. × ⅛ in.) was heated to redness over a Bunsen burner, and a few grams of the dry silver chloride melted on (melting point AgCl, 455° C.). The orange liquid was spread out in a layer about ½-mm. thick, and any scum scraped to the side using a second piece of porcelain. When cold, the sea-green layer was covered with a film of nitrocellulose lacquer and the whole immersed in a 20 per cent solution of sodium thiosulphate for 15–20 min., after which time the opalescent silver chloride layer could be peeled off the porcelain.

After washing the silver chloride in acetone, it was pressed between polished stainless steel disks in a steam-heated press at 4 tons per square inch for 2-min. periods. The plates so produced were stood in gaseous chlorine for a number of hours, in order to ensure complete clarity, and then repressed.

This method provides silver chloride plates about ¼-mm. thick, transmitting uniformly 65 per cent of the incident radiation between $5\ \mu$ and $15\ \mu$—the region studied. They are rigid and tough and suitable for the construction of absorption cells, and are only slowly darkened on exposure to daylight. Artificial light had no detectable influence on the plates over a period of four weeks.

Kremers[2] has described a method, based on a silver sulphide coating, of protecting silver chloride plates against solarization.

Distortion of Fungal Hyphæ in the Presence of Certain Inhibitors

Brian, Curtis and Hemming[1] have recently reported the production by *Penicillium Janczewskii* of a factor having little antibiotic action but causing characteristic distortion of fungal hyphæ growing in its presence. This substance, isolated in a crystalline state and given the formula $C_{20}H_{20}O_9$[2], has been termed 'curling factor'. The description and illustrations of the stunting and curling caused by this factor are strongly reminiscent of the appearance of hyphal tips growing in the presence of a number of relatively simple inhibitory substances (notably methyl *p*-hydroxybenzoate[3]) encountered by me during the course of fungistatic investigations using *Aspergillus niger*, *Penicillium roqueforti* and *Byssochlamys fulva*. Brian, Curtis and Hemming, while referring to earlier records of similar morphological effects caused by the metabolic products of organisms, consider their effect to be distinct from any previously described for pure chemicals. I consider that the behaviour of the esters referred to above is likely to come into the same class of phenomenon as claimed for 'curling factor'.

My investigations have involved hyphæ growing on Czapek's agar (*p*H 4–5; nitrogen as nitrate), and, although records of distortion have been incidental to the principal purpose of the work, certain aspects seem to merit comment. The appearance of affected hyphæ is most characteristic, involving stunting, multiple branching and curling in a peculiar zigzag form. That the phenomenon is not directly associated with the inhibitory action of the substance is seen in a comparison of homologous esters, where increasing chain-length, although markedly increasing fungistatic activity[4], does not proportionately enhance the distortion effect. On the basis of concentration of ester causing a given level of inhibition, the lowest esters, notably methyl, cause much greater distortion. As a result, little, if any, curling of hyphæ is to be seen with those concentrations of higher esters (such as butyl to heptyl) that are low enough to permit growth. Distortion has also been observed for anisic, salicylic and benzoic acids and for phenol; with *p*-hydroxybenzoic acid itself and the *m*-isomer, the effect is either small or absent.

It is of interest to examine the quantitative nature of the relationship. Brian *et al.* have found their 'curling factor' to be remarkably active, permitting marked stunting at 6×10^{-6} molar. In contrast, the molar concentration of methyl *p*-hydroxybenzoate, permitting ready detection of the similar effect with *A. niger*, is of the order 300×10^{-6}—still very much less, however, than that required for the complete inhibition of growth (approx. $3{,}000 \times 10^{-6}$). It is, of course, possible that distortion results not directly from the action of the inhibitor but from a product of the mould's own metabolism with inhibitor serving as precursor. If this were so, the concentration of such a factor might well be very much less than that of the inhibitor initially supplied.

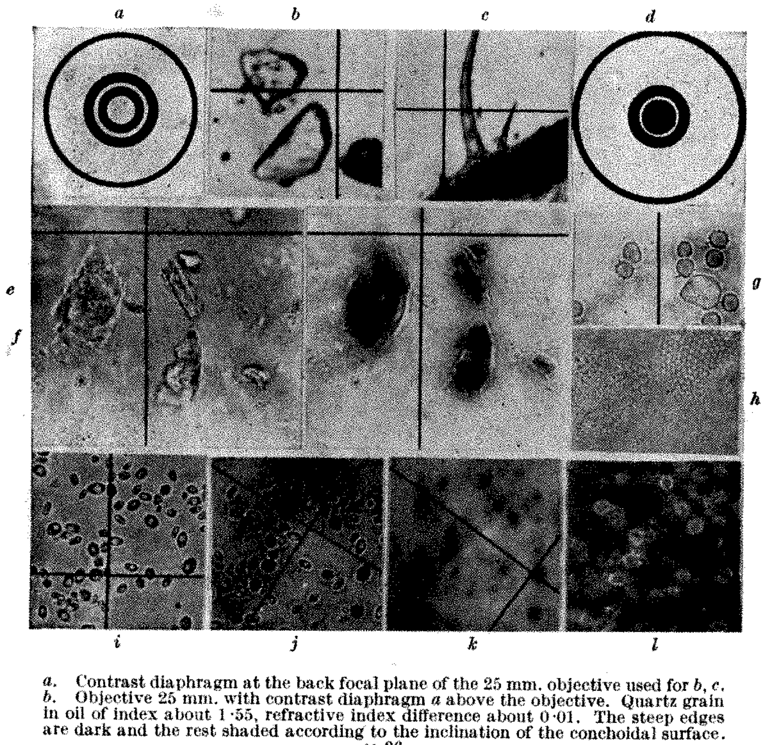
PRODUCTION OF CONTRAST IN THE MICROSCOPE IMAGE BY MEANS OF OPAQUE DIAPHRAGMS

By Dr. A. F. HALLIMOND
Geological Survey and Museum

'PHASE-CONTRAST' methods have recently been widely used to improve the visibility of small transparent objects. The illumination is restricted to a narrow cone by means of an annular diaphragm placed under the condenser, and the direct beam passes through a conjugate annular 'phase-plate' near the upper principal focus of the objective. A theoretical explanation of the effect was given in the original paper by Zernike. It appears to me, however, that Zernike's explanation is insufficient through the omission of an important physical factor, which seems to have been only partly recognized in the later paper by Kohler and Loos. "The details of such an object (transparent) are distinguished only by unequal thickness or refractive index, i.e., they impose on the incident light only phase differences." This statement by Zernike ignores the effect of the inclination of the surfaces that is in fact nearly always present. Methods which render inclined surfaces visible have long been employed by mineralogists for refractive index determination by the Becke line and Schroeder effect. The accompanying photographs (*a–l*) suggest that useful contrast may be obtained by an arrangement of opaque stops, without the use of a 'phase-plate'. It may perhaps be convenient to use the term 'stop-contrast' to distinguish this method from that involving the use of the phase-plate.



a. Contrast diaphragm at the back focal plane of the 25 mm. objective used for *b*, *c*.
b. Objective 25 mm. with contrast diaphragm *a* above the objective. Quartz grain in oil of index about 1·55, refractive index difference about 0·01. The steep edges are dark and the rest shaded according to the inclination of the conchoidal surface. × 36.
c. As in *b*. A leaf-hair in water. There is little injury to the definition. × 36.
d. Contrast diaphragm at back of 4 mm. objective used for *f*, *g*, *h*, *j*, *k*, *l*.
e. 4 mm. 0·85 N.A., *no diaphragm above objective*, the condenser giving ordinary conical illumination. Scales and rouleaux of kaolinite in balsam, refractive index difference about 0·020. Detail is clear with marked Becke lines, but there is little contrast with the background. × 300.
f. 4 mm. 0·65 N.A., contrast diaphragm above the objective as *d*, etc. Detail is still clear, but there is now a marked contrast with the background. × 300.
g. As in *f*. Red and white blood corpuscles. × 300.
h. As in *f*. Diatomite in liquid of refractive index 1·39. × 300.
i. 4 mm. 0·85 N.A., *no diaphragm above the objective*, ordinary conical illumination as in *e*. Yeast in water. Some of the cells in these photos have moved during the exposures. × 300.
j. 4 mm. 0·65 N.A., contrast diaphragm above the objective as in *f*, etc. Yeast is rather strongly refractive and there is little addition to the detail already visible in *i*. No injury to definition.
k. As in *j*. The outer zone of the contrast diaphragm *d* has been covered so that only the direct beam through the annulus is being used. There is considerable loss of definition, the focus in this case being very deep.
l. As in *j*. The annulus has been covered so that only the outer zone of the contrast diaphragm *d* is being used. This gives in effect a 'dark ground' illumination, and the image chiefly consists of bright lines due to the steep edges of the cells.

In phase-contrast, if a given 'point' in the object is to be regarded as an element of a prism rather than as a horizontal surface, the corresponding image of the condenser annulus at the back of the objective will appear as a circle which no longer coincides completely with the annular phase-plate. Part of the 'direct' beam then reaches the eyepiece in differing phase from that which may still traverse the phase-plate, and the image is consequently weakened by interference. By adjusting the opacity of the phase-plate, the amount of light in the two parts of the beam can be matched so as to produce maximum interference. Such an explanation would seem to account for many of the results obtained by phase-contrast, though the full range of these effects has scarcely yet been investigated. The interference method is very efficient in extinguishing the light, but it is open to the objection that when the phase-plate has been adjusted to give maximum contrast for a certain small angular deviation, the more deviated light from other points in the object will mainly miss the phase-plate and will not be extinguished. In such cases an opaque diaphragm may give a wider range of extinction.

Stop-contrast is obtained by using a narrow annular opening below the condenser (in the present case a lens of about 1½ in. focal length), with a conjugate annular opening near the upper principal focus of the objective. Light deviated by the object is eliminated by surrounding the open annulus at the objective with an opaque diaphragm, which in its simplest form might cover the rest of the objective. Such an arrangement is, however, inadmissible since it reduces the aperture and damages the resolving power (photo. *k*). The opaque part of the stop must therefore be usually limited to a certain angular distance immediately on each side of the annulus (*a*). It is sometimes convenient to darken the whole of the relatively small central area (*d*). With a complete stop, practically all the deviated light contributing to the Becke and Schroeder effects would be eliminated. With the dark annuli some extremely deviated rays will still get through the open outer zone, so that steep edges and objects of high refractive index difference may still show a modified Becke line ; but the desired object may be practically free from it, dark contrast being produced instead.

The following incomplete statement indicates the angular values concerned. The maximum deviation that can be produced by a cylindrical object is that for a ray entering and emerging at the grazing angle and will equal $2(90-\theta)^\circ$, where θ is the critical angle. For refractive indices 1·33 (water) and, say, 1·35 (object), $2(90-\theta)$ is 20° in the liquid. If the opaque part of the diaphragm at the back of the objective intercepts rays that occupy this angle, such an object will appear dark except at points near the centre. For low-power objectives with low numerical aperture, the angles that can be covered are much narrower than this, but the method will be sensitive to small differences in refractive index. Higher powers, on the other hand, with numerical aperture about 1·0, will accommodate annuli covering a wider angle that may approach 20°, and they can be made effective for objects of wider deviation.

The accompanying photographs illustrate the results obtainable with low- and medium-power objectives (Cooke, 25 mm., 0·15 N.A. and 4 mm. N.A. 0·65), by means of narrow conical illumination with opaque stops partly covering the back of the objective as shown in *a* and *d*. In these cases the depth of focus is very small and only parts of the object can be in focus, the tendency being to obtain an 'optical section'. Phase-contrast photographs of kaolin were reproduced in *Nature*, **158**, 621 (1946).

The comparison photographs *e* and *i* were taken with narrow conical illumination. This is probably the most satisfactory form of ordinary illumination for objects of small refractive index difference, since it gives a moderate Becke effect without undue loss of light, but the image is mainly due to this effect.

Photographs *c*, *f*, *g*, *h*, *j* indicate that the contrast diaphragm causes no great injury to the resolution of details in the object. *k* and *l* were taken through the annulus and outer zone of the objective, used separately. Neither would supply the detail observed in *j*, although the only difference is that in *j* both areas are open simultaneously. The improvement is presumably due to interference in accordance with Abbe theory.

In ordinary narrow-aperture illumination, a small object in liquid of lower refractive index appears light when the tube is raised, almost invisible when in the focal plane, and dark when the tube is lowered. For a simple isolated object the latter effect resembles that given by contrast methods, but is only produced when the object is somewhat out of focus. When the object is in the focal plane, the use of a contrast diaphragm produces a similar darkening, and the details are in focus. For a complex rugose (or finely granular) object such as the kaolin scales in *e*, the Becke lines overlap in the interior of the object areas, producing a confused mottling which in fact only an experienced observer would interpret as due to a solid object. It is in such cases that the use of contrast methods seems most likely to be advantageous.

The annulus in *d* was purposely made narrow to test the effect on resolution. It is not suggested that this would be necessary in all cases.

This communication has been published by permission of the Director, Geological Survey and Museum.

INDUSTRY AND RESEARCH IN THE SHEFFIELD AREA

THE Federation of British Industries has been holding in recent months a series of conferences on that vital question of the present time, the dependence of progressive industry on research. One of these regional conferences was held in Sheffield on June 5 to discuss the bearing of research on industry in the case of the smaller manufacturing concerns. The problems were considered from two aspects: the first, at a morning session, presided over by Sir Walter Benton Jones, dealt with the part research could play in promoting industrial efficiency, exports and a higher standard of living, with special reference to the industrial problems of the Sheffield area. Sir Walter, in opening the meeting, directed attention to the valuable conclusions of previous conferences, and stated that industry values highly the growth of special research. The afternoon session, Lord Dudley Gordon being in the chair, was devoted to the case of the smaller manufacturing concern which could not afford the cost of a research department, and consideration was given to the research organisations and facilities which could serve it.

The subject of "Research and National Recovery" was discussed by Sir William Larke in a paper full of wise advice of an encouraging and stimulating character. He pointed out that our industrial production needs to be increased above that of 1938 by at least 25 per cent under conditions of a shortage of raw materials and man-power. These requirements point to the need for technical advances, at least as great as those which were achieved during the War. He regards shortage of coal as the principal factor preventing our economic recovery. This difficulty demands still more attention to efficient use, by increased supervision, by continuing to demand of the suppliers fuel of the appropriate quality, and by the provision of more efficient fuel-using plant. Further, our general production efficiency must be at a higher level than that of our competitors. The support of research and closer collaboration of all elements concerned with industry and research are necessary. A survey made by the Federation of British Industries of research activities in British industry has shown a total of some 40,000 staff, of whom 10,000 are graduates of a university or equivalent standard. The total expenditure by industry on research, Sir William said, has increased fourfold in the last ten years, and is now in excess of £25,000,000 per annum, or at least 0·5 per cent of the total value of our annual industrial production. This situation and the potentialities of rapid application of the results of research and discovery to the improvement of industrial efficiency should provide the means of strengthening our competitive power in world markets. The achievements in the face of the overwhelming difficulties of 1940 onwards give hopes of inspiration and encouragement for the future.

Dr. G. P. Jones, discussing the lessons of history in a paper entitled "The Historical Growth and Economic Development of Sheffield Industries", had perforce to limit his scope to steel-making and cutlery. He showed how much we are dependent on the competence of our forefathers, and in what degree an easy livelihood and survival of two terrible wars are owed to their efforts. The historical aspects of the question were also dealt with by Lord Dudley Gordon in reference to valuable contributions to industry which had been made by Sheffield metallurgists. These contributions, as it was put by Sir Charles Goodeve in his summing up of the discussion, showed that confidence is restored by the existence of a momentum of the past.

Prof. R. J. Sarjant, in a paper on "The Industrial Problems of the Sheffield Area and their Solution by Methods of Research", showed how complex the research problems of industry are becoming with the rapid advancement of engineering practice. While the laboratory is still the place for pioneer development, modern research has to proceed to the study of the maze of variables encountered in the plant. This entails the service of the balanced research team—trained research workers, observers and technicians—which in general can only be supplied by the larger research organisation, and in regard to the smaller firm can only be provided by co-operative action. The major problem at present appears to be the better utilization of existing resources. This involves co-ordination of effort, better training and adequate contacts between industrial and research personnel. There is, too, the place of the university, which is, so to speak, on the doorstep. Its function is to inspire the spirit of a 'divine discontent' so useful to research-mindedness, to foster the development of methods which apply to the solution of sociological and technical problems, and to be at the spear-point of the development of research.

Lord Dudley Gordon referred to the potentialities which lie in the institution of the Engineering Research Board. It is patent that demand for men, buildings and equipment has outstripped the supply. It is accordingly expedient to examine what can be done in the circumstances. Where there is no research department, there should be individuals who can collect and study new knowledge, and apply the findings of research done by others to immediate industrial problems. Internal questions of the attitude of management, psychological outlook and methods of organisation must be considered. There are valuable assets in the technical colleges, the scientific societies and advisory services to put inquirers in touch with sources of information. The Research Secretariat which the Federation of British Industries has set up is a valuable instrument in this last respect.

In a paper on "Sheffield Research Organisations, Facilities and Activities", Dr. W. J. Rees outlined the activities of the University, its functions and contributions in relation to the matters discussed, the achievements of the works' laboratories, the wide extent of the work of the research associations, and the facilities available in the technical industries and the efficient library services.

Dr. F. C. Lea finally tackled the main problem of the smaller firms, in a paper entitled "The Smaller Firm and its Application of Research". He took the view that of necessity the small firms have a real live interest in research; they have an essential place in the industrial structure; they can be helped and they can help themselves. The first essential is the need for adequate scientific and technical training of owners and managers. This means better technical colleges and more use to be made of them. These should be provided with staff and equipment to assist in solving the problems of the small firm. Managers should be familiar with what is being done not only in Great Britain but also in other countries. They should be ready, too, to buy new plant and to use new methods.

In the discussion which followed, many points of interest were raised, particularly around the matter of the fear which some managements have of admitting competitors to see what are considered to be secret processes. It was shown, however, that such fears are groundless, and that more is to be gained by accepting the opportunity of learning from others; the competitor usually already knows all about the 'secret' process. Dr. Maddocks referred to the high proportion of trained metallurgists who are being taken into the Armed Services, when industry requires them so urgently, and pressed that something should be done to remedy the position. Prof. Moore emphasized the need for 'putting over' the results of research; he rates it the major part of the problem. Finally, Mr. O. S. Brown, of the Department of Scientific and Industrial Research, outlined the many ways in which the Department is assisting in these matters. Thus help is always available for research in universities for "work of timeliness and promise". An information service has been set up to bring together the man with the problem and the man who can supply the solution. The aims are to create an organisation which is flexible and able to meet the varying needs of industry, to look for the gaps in the organisation and to consider how they can be filled.

In his summing up of the discussion, Sir Charles Goodeve hoped that the Federation would stimulate the examination of the questions discussed. Co-operative action, he said, is clearly called for, as well as more exertion. Much depends upon the technical knowledge of those in executive positions, since they must have sound discrimination in making their important decisions. The small firms may be facing a challenge greater than they have to-day. They should seek knowledge, cultivate a 'divine discontent' and have courage. They might not then long remain small.

HARDENABILITY OF STEEL

In the spring of 1943 a small mission of British metallurgists visited the United States and Canada to discuss the extent to which economy in the use of alloys required for the production of certain special steels could be still further increased. The problem arose from the fact that some of the alloying metals in common use in peace-time were not then available in quantity sufficient to meet the whole of the requirements of the Allies, and alternative steels had to be devised. A most comprehensive account of some of the work done in this direction is included in a "Symposium on the Hardenability of Steel" published by the Iron and Steel Institute, and discussed at a meeting of that Institute on May 14. It should be pointed out—a fact which was not always remembered during the actual discussion—that this work was done under the stress of war-time conditions and that, therefore, there are numerous problems which still await more detailed examination. Fundamental questions of the greatest interest have emerged, and many fields for further work opened up.

The major portion of the papers deal with the end-quench hardenability test—usually known by the name of the 'Jominy test'—the interpretation of the results obtained, and the possibility of using these to predict the extent to which bars of different diameter can be hardened. The influence of boron in increasing hardenability, and, therefore, its potential value in the reduction of the amount of other alloying elements required, is another problem to which attention has been given.

The Jominy test itself has received careful scrutiny, and a most valuable standard procedure for carrying out such investigations drawn up. It must be realized immediately that, in this test, hardness measurements alone are made, and other mechanical properties, therefore, are not taken into consideration. It is well known, however, that these properties, the notched-bar test for example, may vary to a very considerable extent, even with the same steel, and in a condition of identical hardness; the 'temper-brittleness' of some nickel-chrome steels affords an excellent example of this fact. It is clear, then, that while the intelligent use of the end-quench hardenability test may be of great value in providing a preliminary classification of different types of steel, it is equally important to realize that it does not obviate the necessity for other tests where ductility and toughness are of importance.

In view of the 400 pages of papers submitted, the Committee has done well to publish an agreed statement of the principal conclusions reached.

In connexion with the reproducibility of the curves obtained from the Jominy test, it is concluded that the end-quench test is capable of yielding satisfactorily reproducible results provided that the material under test is homogeneous, and that these results are not appreciably affected by small changes in the conditions under which the test is carried out. The end-quench curves determined on different samples of the same ingot, whether forged or rolled to approximately the diameter of the specimen, generally show only small differences. Further, the curves determined on samples from different ingots of the same cast of steel also in general show only minor variations. A marked variation of hardenability may, however, exist across the section even of a single bar, and in general, though not invariably, the hardenability at the centre is less than that at the surface. The hardenability of a steel may also be slightly affected by a variation of the microstructure before quenching. An examination of the hardenability of a hyper-eutectoid chromium–molybdenum steel, for example, suggests that the amount and distribution of the free carbide has a significant effect.

In connexion with the relationship of hardenability and chemical composition, the Committee reports that a wide variation in end-quench hardenability may exist between different casts of steel produced to the same specification, and that even when the variation of composition is taken into account, the hardenability cannot always be calculated satisfactorily from a knowledge of this and the grain size. Dealing with the prediction of the hardness of quenched, and quenched and tempered, bars from hardenability curves, it is concluded that the hardness curves of an oil-quenched bar across its diameter cannot be derived consistently and with adequate accuracy from a single end-quench curve, but that the hardness of a quenched and tempered bar may be predicted satisfactorily from a test specimen which has been end-quenched and afterwards tempered. The combination of mechanical properties obtained from steel that has been quenched and then tempered in the range 500°–650° C. depends on the hardness developed by quenching; but there are as yet serious difficulties in interpreting end-quench curves in terms of the ability of steels to attain any required combination of mechanical properties. Further, the transformation-temperature ranges of steels during continuous cooling can be determined approximately from a series of interrupted end-quench tests.

The Committee, at first under the chairmanship of the late Dr. T. Swindon, and later under that of Mr. D. A. Oliver, has done an admirable piece of work. Where all are so good, it is invidious to pick out any one contribution, but the writer may, perhaps, be allowed to mention his own special interest in Mr. T. F. Russell's theoretical treatment of the Jominy test.

Throughout this work the fullest acknowledgment is made to the previous researches of Grossman, Jominy and their collaborators. Further, Crofts and Lamont of the Union Carbide & Carbon Research Laboratories, Niagara Falls, have delayed publication of their other early and extensive researches for inclusion in this publication.

Some idea of the scope of the interest shown in recent years is provided by a bibliography of 255 papers, all published between 1938 and 1944.

F. C. T.

SOCIAL VALUE OF WAR-TIME MEDICAL RESEARCH

SIR ALEXANDER BIGGAM has published a valuable paper on "War-time Advances in Medicine which might be translated into Civil Practice" (*Edin. Med. J.*, 53, 413; Aug. 1946). In a world war, he says, some medical problems become so important that solutions of them must be found at all costs and, during the Second World War, the attacks upon these problems led to important advances in our knowledge, especially in the practice of preventive medicine.

One of the greatest enemies of the Allied Forces overseas was malaria. It could be argued, in fact, that malaria was our greatest enemy, and it is still the most formidable of the epidemic diseases which attack man. Sir Alexander states that it caused, in Burma at the beginning of the recent war there, nearly half the total sickness experienced. Intensive research on methods of control was therefore imperative, and an enormous amount of research was done. It was greatly helped by volunteers who included members of the Friends Ambulance Unit, students at the University of Oxford, where the Army Malaria Research Unit was situated, and soldiers serving at the Army Medical College. Much research was done elsewhere, and notes upon it have appeared from time to time in *Nature*. The advent of D.D.T., which kills the mosquitoes, and of dimethyl phthalate and other repellents, and of mepacrine, paludrine and the latest addition to our antimalarial drugs, *SN* 13276, have enormously increased our control of malaria. Sir Alexander tells us how these weapons were used in the Far East. His account may be compared with the fascinating story of the eradication of *Anopheles gambiae* from Brazil by a team working for the Brazilian Government and the Rockefeller Foundation (see *Nature*, 153, 765; 1944), a remarkable feat which has been repeated by the same workers in Egypt, where, in the Nile Valley in Upper Egypt in 1943, some 130,000 people died of malaria transmitted by this species of mosquito (see Rockefeller Foundation Report, 1946). A valuable account of the principles and methods of malaria control has also been given by Dr. G. Macdonald, director of the Ross Institute, in his "Notes on Malaria and its Control for Planters and Miners" (April 1946), a pamphlet which discusses, in addition to the principles and methods of control, the malarial parasite itself, its main carriers in the British Empire, the types of land associated with malaria in Malaya and the factors which affect the incidence of malaria.

Another major menace of the Allied Forces in the East was bacillary dysentery. In the British Forces this was treated with sulphaguanidine, but the United States medical men preferred sulphadiazine, which was, they claimed, more effective. Sulphaguanidine, however, is less likely to affect the kidney, and British opinion, therefore, considered that it was preferable in tropical countries where much fluid is lost by sweating and where the sufferer is often dehydrated. Sir Alexander discusses the use of sulphaguanidine, and also the use of D.D.T. against the flies which spread the organisms which cause bacillary dysentery.

Serious also was amœbic dysentery, and much experience of its control and treatment was gained. Sir Alexander especially mentions the cases which resist treatment; and the view that they do so because secondary pyogenic organisms, which infect the intestinal walls already damaged by *Entamœba histolytica*, render these cases intractable. He quotes the work of W. H. Hargreaves (*Lancet*, ii, 68; 1942), which indicates that a preliminary treatment with penicillin and a sulphonamide drug would remove these secondary organisms, so that the attack upon *E. histolytica* with specific drugs such as emetine bismuth iodide, chiniofon, etc., then produces good results. Sir Alexander outlines the treatment which should be given.

Epidemic typhus was not a serious risk in Burma. Mite-typhus (scrub-typhus) was one of the greatest problems encountered in that country. The control of this disease, which is caused by *Rickettsia orientalis* and is transmitted by the larvæ of the mite *Trombidium akamushi* and perhaps by other species of this genus (see *Nature*, **157**, 236; 1946), was helped by attacks upon the mite with dimethyl phthalate. The remarkable story of the mass production of the vaccine against this disease has been told by Fulton, F., and Joyner, L. (*Lancet*, Dec. 8, 1945, p. 729, and Buckland, F. E., *et al.*, *ibid.*, Dec. 8, 1945, p. 734. See also the *Lancet*, Sept. 8, 1945, p. 308). So serious was the menace of the disease that the production of this vaccine was given the highest priority. Special laboratories were rapidly erected, cotton rats, in the lungs of which the *Rickettsia* develops abundantly, were flown from the United States by the R.A.F., and the devoted work of volunteers, who took very considerable risks of severe illness or death during their work (the accidental infection of four of these workers is described by Van den Ende, M., *et al.* (*Lancet*, July 6, 1946, p. 4)), produced enough of the vaccine to inoculate a considerable number of troops in Burma. The collapse of Japan and the withdrawal of Allied troops from the areas in which the disease was prevalent have made it unlikely that the results of this mass inoculation will now give useful information; but research on the vaccine has not ceased.

The rest of Sir Alexander's article is devoted to notes on typhoid fever, only a few outbreaks of which occurred, to warnings about the use of sulphonamides in the tropics where excessive sweating increases the risk of damage by these drugs to the kidney, to penicillin and to laboratory methods of the diagnosis of smallpox and other diseases. There are interesting notes on the importance of preventing sea-sickness in troops about to cross rough seas. Research done by the Medical Research Council in co-operation with military medical men showed that the most useful remedy for it was 1/100 grain of hyoscine given one hour before embarking and repeated every six hours. If the dose has to be continued over a long period, it must be reduced.

In his note on the work of psychiatrists, Sir Alexander says that the successful placing of men, selected by psychological tests, was one of the successes of the recent war. Important also were centres for physical development. A final note on administration points out that medical personnel in an Army Medical Service are under complete administrative control, so that a study of this Service and of the results obtained by it is especially interesting now that a State medical service is to be introduced in Great Britain.

G. Lapage

THE IRISH PILCHARD FISHERY

The fishery for pilchards (*Sardina pilchardus*, Wal.) off the coasts of Cornwall has been famous for many centuries, and also the French, Spanish and Portuguese fisheries for sardines, which are the same species of fish. It is not generally known, however, that there has been also, at various periods, a flourishing Irish pilchard fishery. The appearance of a detailed historical account of the Irish pilchard fishery is therefore particularly welcome as being at once interesting and instructive*.

An Irish pilchard fishery existed so far back as 1591 and probably earlier; but its activities can be traced with some degree of accuracy only from about the year 1611. This is done comprehensively and in detail in the body of the paper, and is admirably summarized at the end.

The records show that the pilchard, when it frequents Irish waters, does so mainly along the coasts of Waterford, Cork and Kerry, although it is by no means confined to those counties. But the fishery has always exhibited extreme fluctuations, and, in recent times, the pilchard appears to have forsaken Irish waters almost entirely from 1904 until 1935. In the latter year shoals began to reappear, and in 1940 pilchards were plentiful once more off Ireland.

Unfortunately, there appears to be no demand in Ireland now for this fish, either fresh or preserved, and a vast potential source of food is not being exploited. But pilchards are occasionally caught when herring and mackerel are being fished, and even then they are usually thrown back into the sea. Nevertheless, the day yet may come when pilchards will command a ready market, even in Ireland, and this record of what the author calls "pilchard years" will then be invaluable. In the meantime, his paper is an outstanding contribution to our knowledge of this fishery over a very long period, and one hopes that its appearance will stimulate someone in a position to do so to prepare a similar historical account of the Cornish pilchard fishery.

G. A. Steven

FORTHCOMING EVENTS

*(Meeting marked with an asterisk * is open to the public)*

Monday, June 23

University College, London (at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Prof. Kapp : "The Presentation of Technical Information", Second Series, 4 : "Some Specific Problems".*

Wednesday, June 25

Institute of Welding (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 2.30 p.m.—Annual General Meeting.

Thursday, June 26

Physical Society, Acoustics Group (at the Royal Institute of British Architects, 66 Portland Place, London, W.1), at 10 a.m.—Summer Symposium on "Sound Absorption and Reverberation".

Iron and Steel Institute (at 4 Grosvenor Gardens, London, S.W.1), at 2.30 p.m.—Mr. F. Fancutt : "The Effect of Different Methods of Pretreating Iron and Steel before Painting" ; Mr. J. C. Judson and Mr. T. A. Banfield : "The Protection of Iron and Steel by Metallic Coatings".

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Prof. M. Born, F.R.S., and Mr. H. S. Green : "A Kinetic Theory of Liquids", Parts 1–4.

Mineralogical Society (at the Geological Society of London, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Scientific Papers.

Friday, June 27

Physical Society (in the Physics Department, Imperial College of Science, South Kensington, London, S.W.7), at 5.15 p.m.—D. J. Morgan : "A Model representing the Action of a Full-wave Rectifier" (demonstration) ; Prof. S. Tolansky : "Applications of Multiple-Beam Interferometry to Surfaces of Thin Films".

Saturday, June 28

Society for Endocrinology (in the Physiology Lecture Theatre, Guy's Hospital Medical School, London, S.E.1), at 10 a.m.—Symposium on "The Assay of Urinary Steroids".

British Psychological Society (at Bedford College for Women, Regent's Park, London, N.W.1), at 2.30 p.m.—Mr. Sydney Crown : "The Use of a Controlled Association Test as a Measure of Neuroticism" ; Mr. E. A. Peel : "A Method for Analysing Value Judgments and Preferences".

Monday, June 23—Saturday, June 28

British Grassland Society and the British Society of Animal Production (at University College, Aberystwyth).—Joint Summer Meeting.

Friday, June 27—Saturday, June 28

Clarendon Laboratory, Oxford.—Conference on "Liquid Helium".

Friday, June 27

At 2.30 p.m.—Opening of the Conference by Dr. K. Mendelssohn.

Saturday, June 28

At 9.30 a.m.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned :

Assistant Mycologist in the Plant Pathology Department—The Secretary, Rothamsted Experimental Station, Harpenden, Herts (June 28).

Senior Technician (Grade A, male), and Technicians (2, Grade B, male), in the Biochemistry Department, a Laboratory Technician (Grade A) with a good knowledge of photography, and a Senior Technician (Grade A) for the Physiology Department—The Secretary, Rowett Research Institute, Bucksburn, Aberdeenshire (June 28).

Lecturer in Mechanical and Workshop Engineering at the County Technical College—The Director of Education (Dept. F.E.), County Education Offices, Stafford (June 28).

Responsible Teacher of Engineering, and a Teacher of Mechanical and Production Engineering Subjects, in the Secondary (Technical) School and part-time Senior Classes of the Batley Technical College and School of Art and Crafts—The Acting Divisional Education Officer, Education Offices, Batley, Yorks (June 28).

Cereal Research Officer, Department of Agriculture, Western Australia—The Agent-General for Western Australia, Savoy House, 115 Strand, London, W.C.2 (June 30).

Assistant Masters in H.M. Dockyard Schools—The Director, Education Department, Admiralty, London, S.W.1 (June 30).

Junior Lecturer, and an Assistant, in Medical Statistics—The Secretary, The University, Edinburgh (June 30).

Speech Therapist—The Clerk of the County Council, County Hall, Newport, Isle of Wight (June 30).

Lecturer or Assistant Lecturer in the Department of Biochemistry—The Registrar, The University, Liverpool (July 1).

Senior Lecturer in Agriculture and Bookkeeping, an Assistant Lecturer in Agriculture, a Junior Assistant Lecturer in Agriculture, and a Junior Assistant in the Poultry School, Auchincruive—The Secretary, West of Scotland Agricultural College, 6 Blythswood Square, Glasgow (July 5).

Lecturer in Biochemistry—The Registrar, The University, Leeds 2 (July 7).

Lecturer in Zoology, an Assistant Lecturer in Zoology, a Lecturer in Biochemistry, and a Lecturer in Physiology—The Registrar, The University, Leeds 2 (July 7).

Senior Cyto-geneticist at Shambat, near Khartoum—The Secretary, Empire Cotton Growing Corporation, 1a Harrington Road, London, S.W.7 (July 12).

Research Physicist—The Ministry of Labour and National Service, Technical and Scientific Register, Room 171, York House, Kingsway, London, W.C.2, quoting A.158/47A (July 12).

Senior Lecturer in Physical Chemistry in the Auckland University College, New Zealand—The Secretary, Universities Bureau of the British Empire, 8 Park Street, London, W.1 (July 15).

Lecturer in Civil Engineering in the University of the Witwatersrand, Johannesburg—The Secretary, Universities Bureau of the British Empire, 8 Park Street, London, W.1 (July 16).

Regional Fuel Engineers, male (London and provinces)—The Director of Establishments, Ministry of Fuel and Power, 7 Millbank, London, S.W.1, quoting 'Regional Fuel Engineer' (July 21).

Second Assistant to the City Analyst—The Secretary and Registrar, The University, Bristol, endorsed 'Second Assistant Analyst' (July 21).

Lecturer in Mathematics in the Canterbury University College, Christchurch, New Zealand—The Secretary, Universities Bureau of the British Empire, 8 Park Street, London, W.1 (July 31).

Professor of Dairy Husbandry in Massey Agricultural College, Palmerston North, New Zealand—The High Commissioner for New Zealand, 415 Strand, London, W.C.2 (September 1).

Scientific Assistant—The Director, Imperial Bureau of Animal Nutrition, Rowett Research Institute, Bucksburn, Aberdeenshire.

Botanist to undertake research on problems relating to the cultivation of *Hevea brasiliensis*—The Secretary, London Advisory Committee for Rubber Research (Ceylon and Malaya), Imperial Institute, London, S.W.7.

Workshop Technician, and Senior Laboratory Assistants (2, men or women), in the Department of Chemistry ; a Laboratory Steward (man or woman), and a Departmental Assistant (woman) interested in museum and herbarium work, in the Department of Botany ; and a Laboratory Technician, in the Department of Geology—The Registrar, University College, Nottingham.

Lecturer, and a Senior Assistant, in the Physics Department—The Secretary, Northampton Polytechnic, St. John Street, London, E.C.1.

Lecturers (2) in the Department of Pure and Applied Science (one should be qualified to teach Elementary Metallurgy, the other should be qualified in Physics)—The Registrar, Loughborough College, Loughborough.

Lecturer in Chemistry—The Clerk to the Governing Body, Battersea Polytechnic, Battersea, London, S.W.11.

Lecturer in the Electrical Engineering Department—The Secretary, Royal Technical College, Glasgow.

Lecturer in Chemistry, a Lecturer in Biology, a Lecturer in General Engineering Subjects, a Lecturer in Pharmacognosy, and a Senior Assistant in Mathematics—The Registrar, Municipal College, Portsmouth.

Assistant for abstracting, reviewing and indexing literature on forestry and forest products—The Director, Imperial Forestry Bureau, Oxford.

Lecturer in Electronics—The Head of the Electrical Engineering Department, Imperial College, South Kensington, London, S.W.7.

Lecturers in Mathematics (one in Grade II and two in Grade III), and a Lecturer (Grade III) in Physics—The Clerk, Birkbeck College, Breams Buildings, London, E.C.4.

Lecturer, and an Assistant Lecturer, in the Department of Zoology—The Secretary, University College, Gower Street, London, W.C.1.

Graduate in Engineering Subjects with special qualifications in thermodynamics—The Principal, Erith Technical College, Erith Road, Belvedere, Kent.

EDUCATION FOR LIVING

THE Central Advisory Council for England was appointed by the Minister of Education under Section 4 of the Education Act, 1944, in December of that year. By the terms of the Education Act it was decreed that "there shall be two Central Advisory Councils for Education, one for England and the other for Wales and Monmouthshire, and it shall be the duty of these Councils to advise the Minister upon such matters connected with educational theory and practice as they think fit, and upon any question referred to them by him. . . ." By agreement with Mr. R. A. Butler, who was Minister of Education in December 1944 and in the early months of 1945, the Central Advisory Council for England decided, as its first task, to examine the content and methods of education in those schools from which "the actual transition from life at school to independent life" is made; and the results of this preliminary inquiry have recently been published in the book entitled "School to Life".*

Since one of the most important and urgent tasks of educationists is to combine fixity of aim with diversity in application, the inescapable question is how general or liberal, as distinct from specialist or vocational, education can be so adapted to differing abilities and aptitudes that, while appealing deeply to each, it can remain in goal and essential outlook the same for all. The larger part of the question is how general education can be so adapted for the great majority, who are possessed of a lower facility with ideas than the intellectually gifted minority, that it can implant the power of thought and expression, the sense of relevance and value. It is, indeed, easy enough to postulate that, if general education is to be adapted to meet the needs of young people with differing abilities and aptitudes, it must make increasing use of what appeals directly to the senses. But merely to make this adjustment will not alone suffice. Those whom ideas leave unmoved must come to know them in more specific forms—mathematics when it is related to some mechanical task, history when it touches some trade, and design when it is wedded to some manufacturing process. Or, again, although some learn of democracy and of its privileges and responsibilities by growing familiar with ideas, all—and more especially the less intellectually gifted—learn also through action and by example; and, for those who see life primarily as action, the adaptation of general education must be such that they are roused to a realization of the connexion between ideas and day-to-day action.

Whatever detailed criticisms there may be of "School to Life", it will be generally agreed that the Central Advisory Council has done well to recognize the urgency of the need for this adaptation. In one striking passage in the report it is categorically declared: "The system is already established of transferring children for the post-primary years of school to some form of secondary school according to their different aptitudes. While the traditional curriculum and methods of the older endowed schools

---

*H.M. Stationery Office. 2*s.* 6*d.*

may continue to meet the needs of many, the majority of children will be attending secondary schools which do not belong to this tradition. . . . Industry may well suggest something both of subject and method which will help rather than hinder their efforts."

It is, however, to be noted that, in citing examples of some of the ways in which the practical element can be introduced to general education at the secondary stage, the Council is insistent that "the danger to be avoided is that of subordinating the whole personality to a narrow conception of industry's need"; and not the least valuable feature of this report is, in consequence, an insistence on the distinction between general education with a technical bias and vocational training. Although the insistence on this distinction has led the Council to accept such questionable conclusions as "works schools are no substitute for county colleges" and "industry should provide its own special training", it has resulted in a balanced appreciation and criticism of education as "a preparation for a useful and satisfying life".

Even if, as has been suggested, the Council has misunderstood its function in addressing this report to a wider audience than was the practice of the Consultative Committee in framing the Hadow and Spens Reports, it has succeeded in focusing attention on the difficulties and uncertainties which have, in the past, needlessly attended "the transition from school to independent life". In endorsing the view, expressed fifty years ago by the Bryce Commission, that secondary education is technical because "it teaches the boy so to apply the principles he is learning, and so to learn the principles by applying them, or so to use the instruments he is being made to know, as to perform and produce something, interpret a literature or a science, make a picture or a book, practice a plastic or manual art, convince a jury or persuade a senate, translate or annotate an author, dye wool, weave cloth, design or construct a machine, navigate a ship, or command an army", the Council is saying nothing that is new. In emphasizing the further conclusion of the Bryce Commission that "technical education is secondary" to that part of education which, in the words of the report of the Harvard Committee on "General Education in a Free Society", looks first to the needs of a young person "as a responsible human being and citizen", it is underlining the most important—and the most neglected—conclusion of the Percy Committee. If there is to-day no need to argue that "the position of Great Britain as a leading industrial nation is being endangered by a failure to secure the fullest application of science to industry", it is, in present circumstances, still essential to subject to the most ruthless analysis the further conclusion that "this failure is partly due to deficiencies in education".

The deficiencies to which the Percy Committee referred are not to be explained solely—or, indeed, satisfactorily—by comparing the provision for technical and other forms of secondary education, or by deploring the number of university graduates in relation to the rest of the population. Those educationists and politicians who imagine that merely to increase the number of those who are given specialist education, whether at the secondary or the university level, is to safeguard the position of Great Britain as a leading industrial nation would do well to ponder the warning in a recent editorial comment of *The Economist* that "there are plenty of managers in this country who cannot manage, teachers who cannot teach; statisticians who cannot count, and women who cannot wash up. The country, in fact, abounds in incompetents. What, however, does not seem to be realized is that this incompetence is not due to lack of training, but reflects the failings of the country's educational system. The remedy is not to give a professional smear to a bad construction, but to secure what is so often overlooked—the training of minds."

The continued failure to appreciate this fundamental need has arisen, in part at least, from the widespread neglect of the dictum that "you may not divide the seamless coat of learning". In the weaving of it there are three strands—accurate knowledge, a wise competence, and a true valuation—and, until each is conceived as an essential and inseparable part of total education, whatever bias it may be given, so long will educationists fail to fulfil their primary responsibility. The true purpose of general education is not to teach the individual many things, or even much, but to afford him the opportunity to 'learn to think' and to 'learn to learn'. To those who realize that, because its purpose is not thus conceived by many who either legislate or teach, there is the further failure to appreciate that technical education can afford a unique opportunity to translate into practice the indivisibility of the educationist's responsibility, the insistence of the Central Advisory Council that "there is no objection on educational grounds to bringing into education anything [illegible] intrinsic interest by way of subject-matter [illegible] process that industry can provide" will be doul[illegible] welcome.

It would, however, be less than honest to suggest that the Council has, on the evidence afforded by "School to Life", fully appreciated the purpose of general education, as opposed to vocational training. Few, if any, educationists would quarrel with the conception of that "complete and generous education" which inspires and gives unity to the Education Act, 1944; but many would not be content, as are the members of the Council, to interpret their conception of a "complete and generous education" by reference to the opening words of the White Paper on "Educational Reconstruction": "The Government's purpose in putting forward the reforms described in this Paper is to secure for children a happier childhood and a better start in life; to ensure a fuller measure of education and opportunity for young people and to provide means for all of developing the various talents with which they are endowed and so enriching the inheritance of the country whose citizens they are". The fundamental weakness of this report—and it is one which largely invalidates the very real distinction which is drawn between general education and vocational training—is the insistence of the Council that the final test of the educated man or woman is the "quality of the individual life". To emphasize unduly the "quality of the individual life" is to ignore the relation of man to society, the concept of democracy as no less a spiritual ideal than a system of government, and the responsibility of private judgment which true democracy imposes on every member of a democratic society and which it is the task of general education to inculcate. Vocational training, by equipping young people for certain tasks, is avowedly competitive in spirit and looks to worldly success. To know how to do something is to have, or seem to have, a possible start in life; and on any view vocational competence is a requisite of worldly advancement. But no society—and certainly no democratic society—can be organised simply in the interests of the fittest and hope to survive. If it were, it would cease to be a political society in the sense in which Aristotle understood the term, requiring a common equipment, open equally to the enjoyment of all, and created by a common effort of co-operation. Ideally, the success of an individual is meaningless or harmful, except as it is the mark of his superior service to the common good; and general education, if its purpose and spirit are rightly conceived, should represent a force in the curriculum of the school, and ultimately in society, which is not in the main competitive.

Of the need for such an interpretation of general education there is to-day no question. While differing abilities and aptitudes appear to be inborn and to grow independently of background and environment, they would seem to be drawn forth or repressed by the spirit of the age; but general education, if it is conceived as an antidote to the competitiveness of contemporary life, could be an essential means of venting that narrowing of the potential gifts of individual which competition enforces. More itively, the acceptance of a common core of ining and knowledge, and its adaptation to meet he needs of differing abilities and aptitudes, could ensure that every young person, irrespective of his bents, learns to share "the common knowledge and the common values on which a free society depends". Even if there must be an academic bias in the education of some, a technical in that of others, and a modern (for lack of a better name) in that of the large majority, each could enter into that heritage of knowledge and values which is concerned to illumine the physical world, man's corporate life, and his inner visions and standards.

An ideal, but not impossible, vision of the democratic society of the future might see it composed of a myriad of smaller societies representing between them all the arts and insights of civilized man. It would be that they might participate in some of these, quite as much as for making a living, that education would prepare young people, and this participation would bring, in turn, that true "quality of the individual life" which is alone the test of the educated man or woman.

BACTERIAL STRUCTURE AND ACTIVITY

The Bacterial Cell

In its Relation to Problems of Virulence, Immunity and Chemotherapy. By Prof. Rene J. Dubos. (Harvard University Monographs in Medicine and Public Health.) Pp. xix + 460 + 22 plates. (Cambridge, Mass: Harvard University Press; London: Oxford University Press, 1946.) 28*s*. net.

IT has been thought that bacteria, with their comparatively simple morphology, are the most primitive forms of living things. It is only in recent years with the development of new techniques and the great advances that have been made, particularly in the field of bacterial physiology, and to a lesser extent in our knowledge of their structure, that their complex and diverse nature has been appreciated. This very diverse nature and the economic and medical importance connected with so many of the micro-organisms have resulted in bacteria being studied from many different angles. There has, in consequence, been a tendency for bacteriologists to remain limited to their own particular field. One of the outstanding values of this admirable book by Prof. Dubos is the co-ordination which he attempts between these various fields, so that one is enabled to view the bacterial cell and its multiple activities as a co-ordinated whole. It will go far to remove such obviously one-sided ideas as to regard the cell as a bag of enzymes or a mass of undifferentiated macromolecules. Dubos covers a wide field, and in the course of 460 pages cannot do more than give a bird's-eye view of the problems involved. Nevertheless, the bird is more of the nature of a lark than an eagle, and frequently comes down to earth to illustrate his points by specific examples. Indeed, there are more than a thousand references, although there is a tendency in the text to group these so that it is not always possible to trace the particular author of an observation cited.

Dubos starts by defining the problems he is up against. He stresses the impossibility of placing bacteria with any certainty into a phylogenetic scheme. His statement that "It is unlikely . . . that the distribution of metabolic characters can reveal the trends of physiological evolution and . . . any attempt to develop a phylogenetic system will have to be based . . . on what morphological characters are available" is open to question. The rather artificial phylogeny of Stanier and VanNiel which he appears to prefer is not very convincing.

Three chapters are devoted to the examination of the structure of the cell both directly, by staining and other microchemical and physical techniques, and indirectly by enzymes specific for various components of the cell, by immunology and bacteriophage action.

There is a natural transition from this to a chapter on bacterial variation. Here are discussed the normal variation occurring during the growth-cycle, adaptation and transmissible variation. In connexion with adaptive enzymes, the conclusion that their production "always involves synthesis of new protoplasm" although cellular division may be absent is no longer tenable in view of the recent work of Pollock and others, who showed that adaptation of both bacterial nitratase and tetrathionase may occur without increase in cell mass. In the case of transmissible variation involving environmental factors, Dubos inclines to the view that this is a selection of an existing mutant. He quotes the work of Lewis on the selection of an existing mutant in *Bact. coli mutabile* very fully, but omits to mention the classical paper of Luria and Delbruck, who by the application of mathematical analysis to their experimental results showed conclusively that bacteriophage-resistant mutants are not induced but merely selected by the bacterial virus. The evidence for life-cycles and sexual reproduction is examined, and the verdict 'not proven' made. The chapter concludes with an account of one of the most significant advances in this field, namely, the work of Avery and his colleagues on the role of desoxyribonucleic acid in the pneumococcus on the production of its specific capsular polysaccharide and the transmutation of one pneumococcal type into another by this substance derived from the latter. It is enormously active: $1/6 \times 10^8$ being sufficient to produce the change, which is transmitted indefinitely.

In the following chapter, the question of virulence is discussed very fully. Dubos points out the vast number of unrelated factors which are concerned in this problem, any one of which might vary independently of the others. Quite apart from the possession of specific soluble antigens, toxins and the like, which no doubt are important factors, there appears to be more deep-seated cellular factors. A rough form derived from a virulent smooth organism regains its virulence when reconverted to the smooth form even when this is effected by smooth vaccines from avirulent organisms. Conversely, a rough form of an avirulent smooth organism remains avirulent even when a smooth vaccine from a virulent strain is used in the conversion to the smooth form. In the transmutation of pneumococcal types by the Avery technique the virulence of the new type depends on the virulence of the initial type from which the 'competent' rough form has been acquired.

Having dealt with the general structure and biology of the microbe, Dubos turns his attention to methods of destroying bacteria or preventing their multiplication. In the chapter on immunization against infection, he traces the historical development of the science of immunity and then considers the antigens of the cell which are responsible for elucidating the protective antibodies. These are not only the type specific antigens, but, as in the case of factors determining virulence, there is evidence that deep-seated non-specific antigenic substances are also responsible. These are present in the *R* forms. One example, however, that he quotes, namely, immunization with avirulent *R* forms of *B. anthracis*, is not really an instance of this, since immunity depends on an extracellular antigen actively produced by the living organism in the tissues of the host and not on a deep-seated antigen already present in the organism.

From this he passes on to consider the mechanisms of protective immunity and factors determining the preparation and standardization of adequate vaccines.

A long chapter is devoted to bacteriostatic and bactericidal agents and their mode of action.

He points out that there has been a return to the specific receptor theory of Ehrlich in the Woods–Fildes hypothesis of "specific poisoning of an essential reaction excited through an interference with a catalyst or essential metabolite". Many examples of this are given. Nevertheless, non-specific physiochemical reactions also occur. He gives examples of such reactions in the formation of unionized complexes between dyes and the acidic or basic groups in the organism, and in the action of surface-active substances. Many of these reactions are not entirely non-specific as they depend on particular acid or basic groups present in the cell. Differences in this respect are found between Gram-positive and -negative organisms and even between species very similar to each other, for example, *Bact. coli* and *Salm. typhi*. He discusses next the question of reversibility and the difference between bacteriostatic and bactericidal agents. This depends on a large number of environmental factors. It is often a quantitative rather than a qualitative difference.

In an addendum, Robinow describes nuclear structures in bacteria. It includes many excellent photographs of bacteria stained by his special method to demonstrate the nuclear apparatus.

This book will certainly rank with Landsteiner's "Specificity of Serological Reactions" as a classic in bacteriological literature. G. P. G.

PAINTER AND WRITER

A Canvas to Cover

By Edward Seago. Pp. 134 + 68 plates. (London: Wm. Collins, Sons and Co., Ltd., 1947.) 15*s*. net.

PAINTER and writer, yes, in that order. One feels that Mr. Seago will agree because he has called his very attractive book "A Canvas to Cover" and not "Paper to Write On". In this way he indicates that the picture comes first, and that his membership is of the band of painters who write rather than of the writers who paint. Thus he may escape the fate of Carl Larsson, who polished his prose with loving care and hoped it would be his memorial, but whose countrymen, deciding otherwise, obstinately continued to prize his paintings more highly than his writings.

Mr. Seago is a painter in the English tradition. He admires Constable—"the supreme master of landscape painting in terms of atmosphere and light"—Gainsborough, Crome and Cotman. Turner is not so sympathetic: "Turner was a great master—he was a caged being trying desperately to free himself". These are the main influences on the painter. But what of the writer? He has read widely; his pages contain quotations from Shakespeare to Shelley and Rupert Brooke, from Leonardo da Vinci to Ruskin and Roger Fry, but none of these has influenced his style, and Ruskin, surely, would have disapproved of "distant snow laying in a valley" (p. 104). At the same time, it is Ruskin who is quoted the most frequently, and that is no bad thing. Admiration of Constable coupled with a liking for Ruskin forms an excellent background for a painter.

The titles of his chapters and the wealth of illustrations show that the author's main concern is with the problems of painting out-of-doors, and it soon becomes evident that he is a close and careful observer of Nature in all her moods. Neither does he neglect the smaller things. He has noticed the behaviour of caterpillars on the railings of Berkeley Square, but is thoroughly confused about water-spiders (p. 72), unless, indeed, he uses 'water-spider' as a vernacular name instead of 'pond-skater'.

There is much sound sense in the text, a refreshing absence of 'isms' and theories, and a curious echo of Tolstoy in the phrase, "more simple people, living nearer the earth, are more touched by the essence of Art". Art itself is defined as "the expression of the senses through the imagination, and the basis is truth", not beauty—"Beauty is certainly not Art". That, of course, is true enough if by beauty is meant merely the sum of those qualities which please the eye, but if beauty is given its philosophical content of wholeness, harmony and radiance, it immediately becomes the major part of art, and comprises the entire intellectual element.

But Mr. Seago is not concerned overmuch with philosophy, although certain of his difficulties can only be solved on that basis. His chief concern is with light, atmosphere and colour, and here he has much of interest and importance to impart. In his opinion grey is the most abundant colour in Nature, not green, and in Great Britain that is so. It is the dominant greyness of the atmosphere which harmonizes colour in Britain to a degree unequalled anywhere else, and which gives to our landscape a quality of serenity and repose lacking in more arid climates. The whole book is full of notes on colour; indeed, one of its strongest points is the way in which the painter's vision is translated into terms the layman can understand. If the artist cannot make us see with his eyes he has done his best to tell us what to look for with our own.

The plates are uneven, for the simple reason that not all the originals are suitable for reproduction in monochrome. As a general rule, swift sketches done with a heavily charged brush do not come out as well as pictures with more finish. Apart from all other considerations, the impasto of the sketch is often a disturbing factor; examples are the spotty, 'pimple-faced' appearance of "White Sails" (facing p. 92), and the fussiness of "Sunlit Spire" (facing p. 113). It would have been better to have reduced the number of photographs to a half or even a quarter, and to have given four more coloured plates in their place. To do so would have added still further to the value of this interesting and stimulating book.

A. TINDELL HOPWOOD

PHILOSOPHY IN ACTION

Power and Events

An Essay on Dynamics in Philosophy. By Andrew Paul Ushenko. Pp. xxiii+301. (Princeton, N.J.: Princeton University Press; London: Oxford University Press, 1946.) 30*s*. net.

IT is becoming clear that, among its other characteristics, the present intellectual barometer, especially in the United States, is set for 'change' rather than for 'fair'. Supercharged clouds are racing across the horizon, and it would not, one imagines, take a great deal to bring the whole thing down in a deluge. The mental image produced by this book is of that kind. A storm is a grand sight, and the pages before us contain grand thoughts. Of that there can be no doubt; and what they have to say is something like this. Classical philosophy was static in ideal and timeless in form. We call it 'taking long views'. The breakaway to a species of romanticism, mixed with more than a trace of the empirical, has produced a clarion call for progress, movement and intuition, with short shrift for analysis. Briefly, then, 'short views', or relatively so.

Dr. Ushenko attempts a reconciliation between these extremes by reviving Aristotle's *potentiality-actuality* as *power-event*. Naturally, there are significant differences, as when the author presents a respectable demonstration that power is an observable entity. Moreover, he adopts the wholly admirable principle of looking for a species of invariant, which might form the desired sheet anchor in transformations from one *Weltanschauung* to another. In this appears the possibility of a metaphilosophic system alongside contemporary work in metalogic and metamathematics. All well and good: what is surprising and encouraging is the setting selected for one of the major manifestations of power. This is none other than art, and the visual arts in particular. Indeed, it may be said that the transition from a typical Italian primitive painting, through the rhythm of the High Renaissance, to the romanticism of the Baroque, demonstrates very accurately corresponding events in the region of pure thought.

Several famous pictures are therefore discussed in terms of vector properties, namely, the capacity of implicit lines to carry over the eye to some essential point of the composition, and thus to generate æsthetic tension. That this is a very real effect was recognized years ago by Birkhoff in his "Aesthetic Measure". It is also amenable to qualitative analysis on a *Gestalt* basis, as I have shown myself in another connexion. A beautiful example given by Ushenko is Leonardo da Vinci's "Last Supper", though what can be learnt from it is perhaps not quite what the present author imagines. He quotes Wölfflin to the effect that the sensation of power is produced by the deliberate use of too short a table, and consequent crowding of the figures. Actually it is more likely that this feeling is caused by the step-wise grouping (not necessarily crowding) of the apostles about an axis passing through the Central Figure, and the 'reflexion' back to the middle suggested by the horizontality of the arms on the extreme right. But above all is Leonardo's choice of the moment of betrayal rather than the conventional one of Communion, as the theme of this sublime fresco. It connotes not peace, but a sword. All this reinforces the general argument in favour of *Sturm und Drang*, or at least a condition of dynamic equilibrium, such as Kekulé once invoked to establish the permanence of his benzene ring.

Thus it is that in the whole section dealing with power the author seems to be at his best. This is his own domain in which he is thoroughly at home. Outside, he discourses upon paradoxes, intuition, probability and so forth. The result here is less striking, and it might be prudent to regard these passages more as valuable comment than as new material. Apparently it is hoped that students will use the book as a text. If they do, they will need some kind of summary at the end of each main chapter (four in all), not as a temptation to skip the rest, but because a novice could not reasonably be expected to have a steady enough hand (and possibly head) to decant the liquor without undue spillage.

The general format is excellent, and the volume is a pleasure to handle. A minor blemish occurs in Fig. 1 (after Köhler). The segmental boundaries are drawn as dotted lines, whereas in the original (English edition) they are solid. The latter is much to be preferred for the fixation test.

To return to where we started. Dr. Ushenko's *Dynamik* is apt to run hot occasionally, and his reactions are a trifle gregarious. No harm whatever, though some of us may conceivably cherish something a little more *intime*, like a certain author of last century who honoured his thoughts by calling them the "companions of my solitude".

F. IAN G. RAWLINS

The Earth and the Stars

By Dr. C. G. Abbot. Pp. xii+288+29 plates. (New York: D. Van Nostrand Co., Inc., 1946.) 3.75 dollars.

THERE are many good books on astronomy intended for the general reader. This book cannot be included among them. It is a revision of a book, bearing the same title, which was published in 1925. But the revision has not been made with due care, and there are numerous errors and inaccuracies. The book is presumably intended primarily for American readers; but this does not justify credit for stellar parallax determinations being given only to American observatories, and the important contributions of the Greenwich and Cape Observatories ignored. The value for the solar parallax, derived from the observations of Eros at the opposition of 1931, is given wrongly. The parallax of Nova Persei 1901 is incorrectly stated; it is the value derived by a method which, as has been often pointed out, is invalid. The only determination of the constant of aberration which is mentioned is an old determination by Doolittle; there are many more recent and more accurate determinations. In view of the identification by Edlén of the origin of the coronal lines, the statement that the green coronal line is assigned to some ionized state of some common element could be improved upon. It is twice mentioned in the same chapter that Harlow Shapley has suggested a total of two hundred billion stars in our own galaxy. The sentence, "total eclipses of the Sun may occur in any month of the year", may be easily misinterpreted by the reader. In discussing the broadening of lines in stellar spectra no mention is made of rotational broadening. There is no continuity of plan in the book, which is scrappy and discursive. The publisher's note describes the book as "the absorbing story of the enigma of the universe: of the stars and constellations and their relationship to the earth". This seems to be a singularly inaccurate description of a book which is not worthy of its author.

La conquête de l'énergie atomique

1: Des Rayons uraniques à la Scission de l'Uranium (1896–1940); 2: De la Scission de l'Uranium à la Bombe atomique (1940–1945). Par Gerard de Vaucouleurs. (Actualités scientifiques et industrielles, 1000.) Pp. 114. (Paris: Hermann et Cie., 1946.) 120 francs.

OF the millions of words that have been written about nuclear energy, almost all are in highly technical (and mostly still secret) reports, or in articles and booklets that seek to explain the mysteries of nuclear physics and 'atom' bombs to the world and his wife.

M. de Vaucouleurs has chosen a middle path; he claims, in his preface, the distinction of not being a specialist in the field of which he writes, and he explains that his little book grew out of an article originally published by the French and Belgian astronomical societies. He has written, in scientific but non-specialist language, a sober but interesting account of the growth of nuclear physics from 1896 until 1940, followed by what is essentially a summary of the official American and British statements on the later developments that culminated in the explosions at Alamogordo, Hiroshima and Nagasaki. It can be read with ease and interest by anyone of scientific education, nuclear physicists included; no expert knowledge of French is needed, for M. de Vaucouleurs writes very clearly.

Names and dates are numerous, and with the aid of *Physics Abstracts* it is easy to locate the many published papers that the author has consulted. The reviewer applied his usual test of typographical accuracy by looking for the third 'c' in Prof. Cockcroft's name, and found it was not always there.

P. B. MOON

Faraday's Encyclopedia of Hydrocarbon Compounds

(Covering the Literature up to January 1st, 1946). Compiled by Dr. Joseph Escott Faraday. Vol. 3: C_8. Pp. cxii+457. (Manchester: Chemindex, Ltd., 1947.) £5 10*s*. 0*d*.

THE appearance of this volume means that the literature is now covered completely to January 1, 1946, for all hydrocarbons C_1–C_8, and by the end of next year it is hoped to publish addenda which will bring the whole work up to the end of 1947; the author has always kept his promises in the past and there is no reason for supposing he will not deliver the goods in the present instance. This will be no mean achievement.

The plan of the present volume must now be familiar to all organic chemists, as it is the same as that of the last; this is a proof, if one were needed, of the excellence of the original arrangement. The value of a compilation of this kind cannot be overrated. The necessity of searching Beilstein and the indexes of numerous volumes of *Chemical Abstracts*, etc., is obviated and all information, completely up to date, is contained in one place. The tedious and time-consuming literature search is a thing of the past, and would that a book such as this were available for all organic compounds and not only for hydrocarbons. Perhaps collaboration between the author and Dr. Dyson is indicated.

One improvement has been introduced: in the case of compounds where a large number of methods of formation are found—in the case of ethylbenzene, for example, there are 212—those that are likely to prove of use in the laboratory are clearly indicated.

The value of a book of this sort depends, of course, entirely on its accuracy, and although the reviewer does not claim a complete check, no errors were detected. The price of £5 10*s*. appears very reasonable for these times, and all chemical libraries should possess a copy.

Nature's Undiscovered Kingdom

By Walter J. C. Murray. Pp. x + 98 + 15 plates. (London: George Allen and Unwin, Ltd., 1947.) 7*s*. 6*d*. net.

THIS is a charming little book on the life of the countryside, from the wide landscape swept by wind and weather down to spiders in the herbage and moths fluttering through the twilight. A tendency to a somewhat "lyrical style" of writing (the words are borrowed from the publishers' note) is compensated for by accuracy of observation and description. The account, for example, of watching and photographing young grey squirrels is quite delightful. Mention of these squirrels reminds us that the illustrations are all from the author's own camera and deserve the fullest praise, in particular the portrait of a grey squirrel facing p. 23. Why the book was given the title of "Nature's Undiscovered Kingdom" eludes me, for this is certainly the kingdom into which Jefferies and Hudson pioneered many years ago: the author is a worthy follower.

F. PITT

THE TRANS-URANIUM ELEMENTS

By Prof. GLENN T. SEABORG and Prof. EMILIO SEGRÈ
University of California, Berkeley, California

BEFORE 1940, chemistry did not know of any element with atomic number greater than 92 (uranium). In spite of occasional claims to the contrary scattered throughout the literature, there still is no good evidence that such elements exist in Nature, except perhaps for minute amounts formed from uranium by neutrons of various origin. This finds its explanation in their instability, since their radioactive half-lives are now known to be small compared to geological times. The last seven years have seen the first positive identification of four trans-uranium elements, of atomic numbers 93, 94, 95 and 96, all discovered as a result of their synthesis by transmutation reactions starting with uranium as the primary material.

The first serious possibility for producing trans-uranium elements was opened by the discovery of artificial transmutation and artificial radioactivity, and particularly by the process of neutron capture found by Fermi and his colleagues in 1934[1]. The new isotopes formed by the capture of neutrons most frequently decay by negative beta-emission, to form elements with atomic numbers increased by one unit, and these workers asked themselves whether the bombardment of uranium should not lead to the element with atomic number 93. At the time they did not suspect the existence of the fission process, and hence they tried to interpret their observed complex of fission-product activities in terms of elements near uranium. The chemistry of the trans-uranium elements was, of course, not known; it was rather generally thought that they would be like rhenium, osmium, etc., the elements immediately above them in the same vertical column of the Periodic Table. Therefore, when their chemical tests showed that the induced activities were not due to elements of atomic numbers 86–92, these investigators naturally interpreted them in terms of several series of trans-uranium elements.

At this point the study of these substances was taken up by Hahn, Meitner and Strassmann[2], and for several years they interpreted their work on the trans-uranium assumption; but gradually difficulties piled up to the extent that this interpretation no longer seemed possible. Further study by these investigators[3] and by I. Curie and Savitch[4] showed that the trans-uranium hypothesis could not be considered satisfactory, since the number of distinct radioactive bodies became too large to fit simply into such a picture. The riddle of the many activities was finally solved by Hahn and Strassmann[5] in 1939 with the discovery of the fission process. Following this great discovery, many workers succeeded in identifying practically all the recognized activities as fission products. However, the important activity of 23-min. half-life, which had previously been assigned by Hahn, Meitner and Strassmann[6] to U^{239}, was confirmed to have been correctly assigned.

As the news of the discovery of fission spread rapidly over the world, many experimental investigations of this process were made. Of special importance to the subject of the trans-uranium elements were some measurements of the range of the fission fragments by the simple method of finding the distribution of fission-product activity in a set of thin foils placed in contact with neutron-irradiated uranium. This was done by many investigators, including Joliot[7] in Paris, Anderson and co-workers[8] in New York and McMillan[9] in Berkeley, California. A by-product of the latter investigation proved in the end to be more important than its original purpose, for in the thin layer of uranium oxide used was found a non-recoiling activity with a 2·3-day half-life, in addition to the expected 23-min. activity ascribed to U^{239}.

This 2·3-day body was immediately suspected to be the daughter of the 23-min. uranium, and hence was suspected to be the isotope 93^{239}. Experiments were made by Segrè[10] to test this genetic relation, but because of the ease with which element 93 exhibits some of the chemical properties of the rare earths, they were interpreted as meaning that the 2·3-day body was a rare-earth isotope.

Final clarity on the subject was brought about by the later work of McMillan and Abelson[11], in Berkeley, which led to their positive identification of a radioactive isotope of element 93, the first trans-uranium element to be discovered. They worked with pure samples of the 2·3-day activity, prepared by exposing thin layers of uranyl nitrate to neutrons from the 60-in. cyclotron and thus allowing the fission fragments to escape by recoil. By a series of chemical experiments they were able to show that the 2·3-day body has at least two oxidation states, the lower one showing chemical properties like the rare earths (and uranium IV and III) and the upper one behaving like uranium VI. They also demonstrated the growth of this body from the 23-min. U^{239}, thus establishing its identity as 93^{239}. Their results were later confirmed by Starke[12] and by Strassmann and Hahn[13] in Germany.

At this point it became obvious why element 93 had evaded earlier seekers, since its chemistry was more like that of uranium than that of rhenium, the most obvious difference from the former being the greater relative stability of the lower oxidation state or states. This similarity to uranium led McMillan and Abelson to suggest that a new series of elements of closely related properties was starting here, similar to the phenomenon which occurs earlier in the Periodic Table with the rare earths. Because of this relation, and the fact that uranium was named after the planet Uranus, McMillan proposed the name 'neptunium' for element 93 and 'plutonium' for its daughter element 94, which was, however, as yet unidentified.

The next step in the investigations at Berkeley was the identification of the element with atomic number 94. It was naturally supposed that 94^{239} would emit alpha-particles, but a search for them in decayed 93^{239} samples showed an activity too weak for good experimentation. Hence McMillan tried bombarding uranium with deuterons, hoping to produce another isotope of element 94 with a shorter half-life. This hope proved to be justified, and he found a definite alpha-activity, giving particles of a range near that of polonium. He was able to say in the summer of 1940 that the body responsible was not protactinium (element 91), uranium or neptunium, but had chemical properties resembling those of thorium (element 90). (This was shown by precipitation as the iodate using Ce (IV) as carrier.)

At this time a change in the nature of the investigation was taking place. The recognition by many people of the military possibilities of fission was having its effect, and the change to an organised programme under military secrecy was inevitable. McMillan was called away for research in the field of radar, and the work was continued at Berkeley by a group including Kennedy, Seaborg, Segrè and Wahl, at first as their own unsponsored research programme but later as part of the organised national war effort. During late 1940 and early 1941, the key to the chemistry of element 94 was found[14], using the isotope resulting from the deuteron bombardment of uranium, which was later shown to be largely 94^{238}. With a very strong oxidizing agent it was found possible to oxidize this element from the IV or III oxidation state to a higher state which is not precipitated as a fluoride, and thus to show that it was indeed a new element. These investigators adopted the name 'plutonium' for element 94, following McMillan's lead for naming trans-uranium elements after the planets beyond Uranus, and they suggested the chemical symbols 'Pu', for plutonium and 'Np' for neptunium. At about the same time, Pu^{239} was finally identified, and the military possibilities[15] of this isotope were established by the experiments of Kennedy, Seaborg, Segrè and Wahl[16], who measured the fission cross-section of Pu^{239} using a sample prepared by decay of Np^{239} and later further purified by taking advantage of the then known chemistry of plutonium. It is, of course, impossible within the scope of this article to describe the development of the chemistry, metallurgy and technology of plutonium from a tracer scale, through the ultra-microchemical or microgram scale and on up to the kilogram scale, and this phase of research and development has been dealt with partially elsewhere[17].

The investigation of the early chemistry of neptunium was limited to studies by the tracer technique using the short-lived isotope Np^{239}, as described above. Fortunately, there is another isotope of neptunium, Np^{237}, which is sufficiently long-lived to make it possible to work with weighable amounts using the methods of ordinary chemistry. This isotope is the decay product of the previously known 7-day beta-particle emitter U^{237}, which is formed[18,19] as the result of an $(n, 2n)$ reaction on U^{238}. This neptunium isotope, first observed, in Berkeley, by Wahl and Seaborg, is an alpha-emitter of very long half-life, $2{\cdot}25 \times 10^{6}$ years. Very fortunately, it is produced in the large uranium chain-reacting units in weighable amounts, so that the chemical properties of neptunium can be, and to a large extent have been, studied by the methods of ordinary chemistry and microchemistry.

More recently the next two trans-uranium elements, with atomic numbers 95 and 96, were discovered. During 1944 and 1945, Seaborg, R. A. James and A. Ghiorso, working at the Metallurgical Laboratory of the University of Chicago of the Manhattan District, identified in the products of the bombardment of Pu^{239} with 40 MeV. helium ions in the Berkeley cyclotron, two isotopes of element 96 of mass 240 and 242, that is, 96^{240} and 96^{242}, formed by (α, n) and $(\alpha, 3n)$ reactions. These isotopes are alpha-emitters with half-lives of one month and five months, respectively. At nearly the same time but somewhat later, Seaborg, James and L. O. Morgan at the same Laboratory identified an isotope of element 95 with mass 241. The 95^{241} is the daughter of a relatively long-lived beta-emitting Pu^{241}, and emits alpha-particles with a half-life of about 500 years. This work was made possible by the vital participation and co-operation of J. G. Hamilton and his group at the University of California, who had recently rebuilt the Berkeley 60-inch cyclotron to produce the required high-energy particles, and who performed the bombardments.

The chemical investigations on the tracer scale have shown that these 'trans-plutonium' elements are almost exclusively tripositive in aqueous solution. They behave chemically very similarly to the tripositive rare earths and can be separated, especially element 96, from the rare-earth elements only with difficulty, using fractionation methods. Apparently, stable tripositive element 96 contains seven *f* electrons with a structure analogous to stable tripositive gadolinium.

It is not possible, of course, to name elements 95 and 96 after planets beyond Pluto, since no such planets are known. These investigators have suggested the name 'americium', symbol 'Am', for element 95, and the name 'curium', symbol 'Cm', for element 96. These are suggested on the basis of the similarity with respect to *f* electrons of the electron structure of element 95 and the rare earth europium, and of element 96 and the rare earth gadolinium. Thus element 95 would be named after the Americas, or New World, by analogy with europium, which was named after Europe, and element 96 would be named after Pierre and Marie Curie, historical leading investigators in the field of radioactivity, by analogy with gadolinium which recalls Gadolin, the investigator of the rare earths.

There has been a great deal of speculation throughout the years as to the possibility of the existence in Nature of isotopes of the trans-uranium elements. The present state of knowledge of their chemical properties makes it possible to make efficient and meaningful searches for such elements. In fact, Seaborg and M. L. Perlman, early in 1942, made a chemical separation of neptunium and plutonium from a quantity of pitchblende ore, and were able to show the presence of a small quantity of alpha-activity in this trans-uranium fraction which they attributed to plutonium, the isotope Pu^{239}. The amount of plutonium in the pitchblende corresponded to about 1 part in 10^{14}, an amount which could not possibly have been found had the chemical properties not been known. This plutonium isotope is present in such uranium-containing ores, in spite of its relatively short half-life, probably because it is continuously formed by the absorption in U^{238} of some of the neutrons which are always present. A particular source of neutrons, sufficient in amount to account for the presence of this amount of plutonium, results from the spontaneous fission of uranium. It seems likely, in view of their relatively short half-lives, that the other trans-uranium elements could be present only as a result of a similar mechanism for formation, and hence will be present in such ores only at concentrations even smaller than that found for plutonium.

In conclusion, we wish to thank our colleague Prof. E. M. McMillan for supplying part of the material for this article and for helping in its preparation.

THE ZOOLOGICAL SURVEY OF INDIA

By PROF. H. MUNRO FOX, F.R.S.
Bedford College, London

THE Zoological Survey of India was founded in 1916. It derived from the Zoological Section of the Indian Museum. The latter was a descendant of the zoological portion of the Asiatic Society of Bengal. Annandale, a first-class naturalist and an authority on freshwater faunas, was the first director of the Survey. He had distinguished successors in Kemp, Sewell, and Prashad, and, when the last-named was lately called to be adviser on fisheries to the Government of India, in Dr. B. N. Chopra, the present acting director. Other members of the Survey who have achieved a high reputation are Dr. S. L. Hora, who for the past few years has been director of fisheries in the Province of Bengal, and Dr. H. S. Pruthi, recently selected to be director of the new Plant Pest Protection Bureau. From the beginning, however, the staff was small, and unhappily retrenchment in the early nineteen-thirties so much reduced it that the Survey was forced almost to abandon field work and to restrict itself to museum activities, thus cutting out its main purpose, namely, the animal survey of India. Indeed, the staff then became so small that even the proper care of the large and valuable collections became difficult.

The objects for which the Survey was founded were the following. First, it was to undertake faunistic studies so as to acquire all possible information on the geographical distribution of Indian animals; secondly, to maintain and add to the national zoological collections started nearly a century and a half ago by the Asiatic Society of Bengal; thirdly, to maintain and develop the public exhibits in the Indian Museum; fourthly, to identify specimens as required by investigators in any part of the country; and fifthly, to advise the Government on zoological matters. It is clear that the Survey has the functions of the British Museum (Natural History) in London with the obligations of the field survey in addition. This is an immense task in a country of the size of India.

In zoology, as in all the sciences, investigators will go on making discoveries for their own sake, from purely scientific curiosity. This is how fundamental science advances. Some of these discoveries are from time to time made use of for human benefit; no one can foretell which of them will be useful. The Zoological Survey of India functions in just this twofold way, and must continue to do so. Discoveries made by its staff in the field and in the laboratory may any of them be of inestimable value to India. This applies to medical zoology, which means animal pests and animals which transmit pests, to veterinary zoology, to agricultural science and forestry We may take one case a little more in detail, a case which is particularly important in view of the food shortage of to-day, namely, the fisheries. There is great need of developing and expanding the Indian fisheries, both marine and freshwater. More fish should be got out of the Indian seas, always taking care to avoid the danger of overfishing. Inland fishes could be more extensively and better grown in tanks. For all this, much knowledge is needed of the lives of the fishes. No doubt many of the necessary studies will be made in the universities, but the Survey must be the centralizing body, with its collections for the final precise identifications. It is seldom realized by non-biologists that all investigations must be based on the bedrock of accurate determination of the species of organism studied, and this is very much a specialist's responsibility. For development of the Indian fisheries there is also an urgent need for the establishment of at least one marine biological station, perhaps at Karachi where the fauna is good, and this should be closely linked to the Survey. It must be a research station such as that of Plymouth, with a permanent staff, adequate modern equipment, a research vessel, and a library.

In 1880 the Secretary of State for India commenced publication of the important series of monographs that bears the title of "The Fauna of British India". The early authors of these monographs were British, resident in India; for example, Dr. N. Annandale, Lieut.-Col. H. H. Godwin-Austen, Lieut.-Col. C. T. Bingham, W. T. Blandford, Lieut.-Col. Sir S. R. Christophers, Francis Day, Lieut.-Col. F. C. Frazer, G. F. Hampson, and Lieut.-Col. J. Stephenson. The first Indians to prepare monographs were S. Maulik, then professor of zoology in the University of Calcutta, and Dr. B. L. Bhatia; future volumes have been entrusted to Dr. Bhalerao, Dr. Chopra, Dr. Hora, Dr. Prashad and Dr. Sharif. With the introduction of self-government, the responsibility for the continuation of this series falls on the Government of India, and the editor of future volumes will be the director of the Zoological Survey of India: it is expected that many of the authors will be Indians, and the source to which one looks primarily for such experts is the Zoological Survey.

Last year Lieut.-Col. R. B. Seymour Sewell, formerly director of the Survey, returned to India at the invitation of the Government to submit proposals for the reconstruction and expansion of the Survey. His report was issued in November.

It is a document of great importance to the future of the Survey and of India. Sewell makes it clear that an enlarged Survey is essential to the scientific and economic advancement of the country. There should be a very considerable expansion of the staff. Originally there were four officers, then seven, now only five. There should be at least two dozen in the near future, so that each branch of the animal kingdom shall have its expert. One of the new officers would be naturalist to the Marine Survey. This would be a revival of the surgeon-naturalist's post, so fruitful in the past in the deep-sea work of R.I.M.S. *Investigator*.

The immediate difficulty will be to fill these zoological posts. Early this year I was in India as a delegate to the Indian Science Congress and then visited a number of the universities. Some of the zoology departments were excellent, others less good; but in most of them the standard could well be raised. In Indian universities zoology has not been so much developed as some of the other sciences. This is, no doubt, a matter of tradition, hard to change. In addition there are in India very few field naturalists. This means that first-class personnel for expanding the Survey will not easily be found. Sewell has put forward a scheme for the training of young Indian zoological graduates of the universities for two years in the Survey and then for a year abroad.

The Survey, with all its valuable collections and library, was moved for safety during the War from Calcutta to temporary quarters at Benares. There it is to-day, quite inadequately housed. There is insufficient room either to tend or to consult the collections, and the building is liable to floods which have already damaged valuable books. The Survey has the best zoological library in India, probably in Asia. Sewell recommends the erection at New Delhi of a new home for the Survey in a fire-proof, air-conditioned building. Here it would be placed centrally for Government consultation, situated near other scientific institutes.

When India assumes independence she cannot afford to neglect the expansion of her Zoological Survey.

NEW PHYSICO-CHEMICAL PHENOMENA IN THE DEFORMATION AND MECHANICAL TREATMENT OF SOLIDS*

By P. REHBINDER

Member of the Academy of Sciences of the U.S.S.R.

THE mechanical structural properties of solids—elasticity, plasticity and strength—are of paramount importance in most branches of modern engineering. These properties, which are determined by molecular interaction, are usually investigated without resorting to advanced physical chemistry. However, the methods of physico-chemical investigation of the deformation of solids, with due recourse to the factor of the chemical composition of the surrounding medium, lead to new methods of controlling the mechanical properties of solids and to novel methods of their mechanical treatment.

The earlier investigations by the author and his associates have established the fact that the addition to the surrounding medium of small amounts of the so-called surface-active substances, the particles of which are adsorbed on solid surfaces, is capable of considerably lowering the resistance of a solid to stress.

These very general phenomena of facilitating strain and disintegration of solids by adsorption have been extensively utilized by the author and his co-workers, and afterwards by many other investigators, both in the Soviet Union and abroad in various practical fields. For example, they have been used to facilitate the boring of stable (hard) rocks, in various processes of disintegration of solids by milling, in cutting and pressure working of metals, etc. It is this phenomenon of adsorptional promotion of strain that largely accounts for the effect of cooling lubricants, in the absence of which some of the above processes become altogether impracticable. The theory of this phenomenon must underlie any scientifically based selection of these lubricants.

During the Second World War, mainly in connexion with the application of these investigations to the machining of metals, we succeeded in elucidating to some extent the mechanism of the adsorptional promotion of strain and, at the same time, in discovering a number of new phenomena in this domain.

It was ascertained that these phenomena are associated with the penetration of surface-active substances into the depth of the strained solid along the surface of the wedge-shaped ultra-microscopic cracks which are developed in course of deformation. After unloading, that is, removal of the stress, the micro-cracks become closed again, the surface-active substances adsorbed on their inner surface are expelled by molecular cohesion and the original mechanical properties of the solid are restored.

The closing of the micro-cracks after unloading is a process involved not only in elastic but also in plastic deformations, with the sole difference that, after shear involving slippage, the closing of the cracks takes place at new points of their surfaces.

These investigations have led to the discovery of some new phenomena which have been described in the report referred to above, and partly demonstrated in a micro-cinematographic film. Special interest is presented by two effects resulting from the penetration of surface-active substances into the micro-cracks: the retarded elastic deformation in mica crystals and the structural changes on plastic deformation of metals.

When a sheet of mica is bent or stretched in absolutely dry air, the deformation occurs practically instantaneously as soon as the external force is applied, and disappears also instantaneously after removal of the stress when the latter is below the elastic limit. In the presence of moisture, however —in water vapour or when the crystal is wetted with water—a gradual increase of deformation on application of stress is observed and a gradual decrease on removal of the stress. On addition to the water of organic substances readily adsorbed on mica, for example, alcohols, this retardation is still further enhanced, and the time required for the deformation to attain its maximum or to disappear after unloading is a matter of some three days. Complete recovery is observed in the case of these phenomena.

So long ago as in the experiments of I. Obreimov on the cleaving of mica along the cleavage planes *in*

---

* Summary of a report at a general meeting of the Academy of Sciences of the U.S.S.R. in July 1946.

vacuo, it was demonstrated that the cleft formed by introduction of a glass wedge is closed again on removal of the latter, so that subsequent cleavage requires almost the same amount of mechanical work. This phenomenon underlies the ingenious method suggested by I. Obreimov for measuring the surface tension at the cleavage faces of mica. The cleavage of mica in such experiments is quite similar to the formation of wedge-shaped micro-cracks, which, according to our concepts, are developed in the region of elastic deformations without any rupture of the solid. As has been kindly pointed out to us by Prof. I. Frenkel, such a concept of reversibly closing micro-cracks leads to the elimination of some grave flaws in Griffith's well-known theory and opens new ways towards its substantial improvement.

In studying the plastic flow in single crystals of the purest tin, it was established that under the action of the surface-active substances (for example, oleic acid or cetyl alcohol) added to the surrounding inert medium (purified paraffin oil), the number of the layers formed which slip over each other on extension of the single crystal increases fifteen-fold or more, whereas their thickness decreases in proportion. These phenomena were observed by means of accelerated micro-cinemaphotography of the stretched single crystals. The sorption of the organic surface-active substances by the strained metal lowers the yield value of tin to half the original value, facilitating the flow by a kind of 'internal' lubrication of the slip planes. Such sorption manifests itself in the abrupt fall of the electrical conductivity of tin, which on removal of the external stress is gradually restored as the original mechanical properties of the metal are restored.

In the case of ordinary, small-grained zinc and copper, the strain-hardening of the outer layers was found to increase sharply after periodic deformation in the presence of surface-active substances. The adsorptional lowering of the hardness of the metal originally observed on deformation is followed by its sharp increase due to a secondary phenomenon: strong disintegration of the crystal grains or their orientation (formation of texture), which always leads to hardening. Some new electrocapillary phenomena were also observed and investigated, namely, the lowering of the hardness or strength of metals in solutions of electrolytes when the surfaces of the micro-cracks formed are charged electrically, irrespective of the sign of charge.

The seat of the above peculiar surface phenomena is thus the inner surface of the micro-cracks which are developed in a strained solid. The latter is, as it were, a kind of labile adsorbent, the newly formed surface of which gradually disappears again after unloading. The whole set of phenomena of adsorptional promotion of deformation in a solid can be regarded as evidence in favour of our concepts regarding the continuous development of micro-cracks in the process of deformation, beginning from the region of elastic deformations.

The elucidation of these phenomena is evidence of the fruitful result of resorting to physical chemistry in the problems of physics and mechanics of solids. This boundary domain of science can in general be said to be of great practical importance in the solution of the problems involved in the working and machining of metals and other solids, as well as in the theory of wear, creep, corrosion, fatigue and a number of other problems in the applied physics of metals and building materials.

THE FIRST CHEMICAL JOURNAL

By Prof. JAMES KENDALL, F.R.S.

In connexion with the forthcoming centenary celebrations (postponed from 1941) of the Chemical Society, the discovery of the first volume of the proceedings of an older organisation in the same field is of timely interest.

This volume—a well-bound folio of 452 pages in copper-plate manuscript, inscribed simply "Chemical Society instituted in the beginning of the year 1785"—was presented to the Royal Irish Academy by Sir William Betham on January 26, 1846, and lay unnoticed in its library for more than a century. Recently, however, it attracted the attention of the Rev. P. J. McLaughlin, of St. Patrick's College, Maynooth, and through an article written by me in the July 1942 number of *Endeavour*, Dr. Farrington, librarian of the Academy, and Dr. McLaughlin were able to identify it as Volume 1 of the *Proceedings of the Chemical Society of the University of Edinburgh*. Practically all the thirty-two communications which it records *in extenso* represent, in fact, papers read at meetings of this Society by members whose names are on Joseph Black's "List of the Members of the Chemical Society, 1785".

That it should have found a resting-place in Dublin is not really surprising. The nationality of nineteen of the fifty-nine original members of the Edinburgh society has been definitely established; of these only three were native Scots, three English, and the residual thirteen were Irish! Presumably the unknown secretary, to whose admirable diligence the volume owes its existence, was one of this majority and retained possession of his handiwork on his return to Ireland.

At my request, the Council of the Royal Irish Academy agreed to send the volume on loan to the Royal Society of Edinburgh for my inspection. Unfortunately, the communications do not include anything of major scientific importance, and my expectation that the volume might afford a unique record of contemporary chemical thought has not been realized. I had hoped to find some lively discussions (with Joseph Black himself participating) on the revolution that Lavoisier was then leading against the phlogiston theory, but this is rarely even mentioned. Most of the papers are routine descriptive chemistry of the classical period, and the most promising of the few exceptions, "an attempt [by Mr. Thomas Beddoes, later director of the Pneumatic Institution and supervisor of Humphry Davy] to point out some of the consequences which flow from Mr. Cavendishes discovery of the component parts of water" peters out, after an attractive start, into an addendum entitled "a conjecture concerning the use of Manure"!

This disappointment, however, emboldened me to make a second request to the Council of the Royal Irish Academy, that it should present the volume to its original owners, and to that request it has now graciously consented. The oldest chemical society in the world will certainly treasure the first volume of its proceedings as a priceless possession. Even if it has no great intrinsic value, it does after all constitute the first journal extant of a purely chemical character, the *Annales de Chimie* being initiated just five years later; and extracts from it may well prove worthy of wider publication.

OBITUARIES

Prof. Edouard Chatton

EDOUARD CHATTON, professor at the Sorbonne and director of the Marine Biological Laboratory at Banyuls-s-mer, corresponding member of the Paris Academy of Sciences, died on April 23, at the age of sixty-three, after a long illness. The French protozoological school loses one of the best—and probably the most brilliant—of its research workers.

Chatton was a pupil of Yves Delage. In 1907 he became Felix Mesnil's assistant at the Pasteur Institute in the department founded by Alphonse Laveran. Seriously wounded on the Champagne front in 1915, he went to Tunis, where he received the hospitality of Charles Nicolle at the Pasteur Institute. When Strasbourg returned to France, he was appointed as lecturer at the new University (1919), and on Bataillon's departure he became director of the Biological Institute. But his constant aim was to work in a marine laboratory. In 1932 he was elected professor at Montpellier and director of the Sète Marine Station. Finally, in 1938, he migrated to Banyuls-s-mer, one of the Sorbonne's marine stations, where he ended his life and career.

Although Chatton made fruitful incursions into the field of parasitic copepods of ascidians and sponges, and on lower parasitic Metazoa (*Orchitosoma*), almost all his activity was devoted to the study of Protozoa. His work increased to a notable extent our knowledge of numerous groups and has been the source of many general and theoretical implications.

Chatton started his scientific career in 1906 with the discovery of the parasitic dinoflagellates. A remarkably large number of new types was found, exhibiting all degrees and sorts of parasitism: external, intestinal, cœlomic, intracellular. The different types show profound changes in morphology, and in kinetics of cell cleavage; but the morphology of the spore remains that of a typical dinoflagellate. That was the origin of fruitful considerations on parasitism and its action on cellular morphology and physiology. From the study of the nucleus, he believed that *Haplozoon*, the curious parasite of annelids, was a parasitic dinoflagellate, a prediction which turned out to be true.

The careful observation of the coccidian nucleus led Chatton to conclude that Coccidia also had their origin among dinoflagellates; and after twenty-five years, shortly before the end of his career, he himself had the satisfaction of discovering the extraordinary dinoflagellates, the Coccidinides, which are parasitic in dinoflagellates. The life-cycle of these organisms is a coccidian one, but their gametes are typical dinoflagellates.

The study of nuclear fission in *Vahlkampfia* was the basis of our understanding of the type of mitosis in Protozoa and of the shattering of the "Nukleol-Centrosom" theory. When studying the life-cycle of *Entamœba dysenteriæ*, Chatton discovered the four-nucleate metacystic stage. He discovered also many new types of parasite and worked out the life-cycle of hitherto completely enigmatic organisms, such as *Pansporella*, *Siedleckia*, *Amœbidium*, *Sporomonas*, etc. He also devoted much of his time to the study of free-living and parasitic ciliates. The understanding of the affinities of the ciliates of the gills of Molluscs led to the exclusion of Hypocomidæ from the suctorians. The genesis of the sucker from a centrosome was one of the newest conclusions of this work.

The Apostomea led to much more important discoveries: the existence of two-host cycles in ciliates; the discovery and description of ciliary metamorphosis; the recognition of some of the general laws of the morphology of ciliates: the cinetosome (basal granule) is a self-reproducing body always located at the [illegible] of the ciliary 'line'; the trichocysts are formed by cinetosomes, as are the cnidocysts of the dinoflagellate *Polykrikos* (another of Chatton's discoveries). These general conceptions were verified on numerous other types of ciliates.

Chatton discovered also new Mycetes, the polysporal bacteria *Metabacterium*. He was the first to obtain the bacteriologically pure culture of an intestinal parasite—*Trichomastix* of the lizards.

Finally, to crown a fruitful career, comes the work accomplished with Madame Chatton on the determinism of sexual reproduction in some ciliates. With bacteriologically controlled cultures, the Chattons have shown that many conditions govern the determinism of copulation: a certain degree of inanition, the nature of the bacterial species present, a 'zygogenic factor' (calcium or ferric chloride, pyruvic acid, etc.) and a certain limiting *p*H value. The copulation of *Glaucoma scintillans* could even be produced at will in bacteria-free cultures.

This is only a brief summary of some of Chatton's investigations. Some three hundred papers represent the result of forty years of almost uninterrupted and concentrated work. Chatton had an extensive knowledge of zoology and parasitology, botany, cytology and microbiology. He possessed also, allied to an almost violent and exclusive love for Protozoa, a peculiar sense which enabled him to recognize every known protozoon, and to guess at first sight the life-history of so many mysterious micro-organisms. So has Chatton's work dominated protozoology. General cytology and protozoology itself have still much to gain from his theoretical conceptions.

Edouard Chatton's death deprives protozoology and biology of one of its most accomplished, brilliant and productive workers. ANDRÉ LWOFF

Mr. B. H. Barrett

BENJAMIN HILTON BARRETT, who died on June 9 after a short illness, at the age of fifty years, had for many years been a lecturer in geology at the University of Glasgow, where he graduated as a student of the late Prof. J. W. Gregory. His main interests were in stratigraphy, but he had made extensive contributions to the petrology of the red rocks of the west of Scotland, particularly of Arran and Dumfriesshire. He collaborated with Gregory in writing a book on general stratigraphy. His most important work, however, was probably that on the small coalfield of Canonbie, on the borders of Dumfriesshire and Cumberland. In collaboration with Dr. J. E. Richey he published, as a 'war-time pamphlet' of the Geological Survey, an account of this coalfield which greatly modified the interpretation of its sequence and structure, and indicated the possibilities of considerable developments in its concealed areas. For some time he was secretary of Section C of the British Association. He had also been an active supporter of the Glasgow Geological Society, of which he was president.

Barrett was a loyal colleague and a cheerful companion, a geologist of sane judgment whose early death is a loss to Scottish geology. A. E. TRUEMAN

NEWS and VIEWS

Scientific Advisory Department for Defence, Australia :

Mr. A. P. Rowe, C.B.E.

It has recently been announced that a Scientific Advisory Department for Defence is to be formed in Australia under Mr. A. P. Rowe. Mr. Rowe is probably best known as the war-time chief superintendent of the Telecommunications Research Establishment, Great Malvern, where most of the research on radar for the Royal Air Force was carried out. It was not, however, in the field of radio that his first research work was done, but in investigations into the ballistic properties of bombs. This work was carried out at the Air Ministry research station at Orford Ness, and notable contributions were made to the technique of high-level bombing. A. P. Rowe's connexion with radar began when he was appointed secretary to a committee under Sir Henry Tizard undertaking a scientific survey of the problems of air defence. He soon appreciated the importance of this new technique being developed by Sir Robert Watson-Watt and his colleagues, and it was in no small measure due to his vision and enthusiasm that research was intensified with the view of establishing quickly an early warning radar system and of investigating the application of radar technique to the problems of air warfare. In 1937 he succeeded Watson-Watt as superintendent of the Bawdsey Research Station. After the outbreak of war he gathered together many leading men of science, and the Bawdsey team grew into the large establishment known as T.R.E. (Telecommunications Research Establishment). He was quick to appreciate the extreme importance of centimetric waves for radar, and under his direction research in this field was pursued at high pressure and led to many of the outstanding radar equipments developed during the War.

Those who worked under A. P. Rowe during the War have the greatest admiration for the way in which he inspired and led so large and varied a team. Many of his methods of scientific direction were novel; for example, his well-known 'Sunday Soviets', where high-ranking officers and scientific men frankly discussed the outstanding problems of the War. On the termination of hostilities, Mr. Rowe felt that his work at the Telecommunications Research Establishment had been completed, and after a short period with the Admiralty he went to Australia to advise on the construction of the rocket-firing range for the Ministry of Supply and the Australian Government. A. P. Rowe's chief interests are in the application of scientific methods to defence; the need for the British Empire to lead in this field might almost be said to be a passion with him. Australia is indeed fortunate in having such a man to guide a department to advise on the scientific aspects of defence.

British Journal of Nutrition

The need for a journal dealing with the scientific aspects of nutrition has long been felt in Great Britain, and, but for the War, its publication would have been one of the first preoccupations of the Nutrition Society. In war-time, however, the practical application of nutrition was deemed of more immediate importance, a circumstance which led to the founding of the Society's *Proceedings*, in which reports of its conferences on practical problems of nutrition are recorded *in extenso*. The field of nutrition occupies an important part of the domain of preventive medicine, and it was fitting that in launching this publication the Nutrition Society should have had the help and support of the Royal College of Physicians in the person of Lord Moran, its president. With a return to slightly more normal times, the Society has been able to realize its original wish. Arrangements have been made with the Cambridge University Press for the production of a quarterly journal, the *British Journal of Nutrition*, which will be devoted to the publication of original work in all branches of nutrition. The fifth volume of the *Proceedings*, recording conferences held during 1946, will be the last to be published separately; in the future, they will be merged in the new journal. Abstracts of communications made at ordinary scientific meetings, a new venture of the Society, will also appear in the *British Journal of Nutrition*. The editorial board will consist of D. P. Cuthbertson, J. N. Davidson, R. C. Garry, G. Graham, J. Hammond, L. J. Harris, E. M. Hume, S. K. Kon (chairman), I. Leitch, W. C. Miller, B. S. Platt, J. A. B. Smith, and F. Yates.

The first number of the new journal will probably appear before the end of the summer. Papers for publication and letters on editorial matters should be sent to Dr. S. K. Kon (*British Journal of Nutrition*), National Institute for Research in Dairying, Shinfield, nr. Reading, Berks. Subscriptions and inquiries about the *Journal* should be addressed to the Cambridge University Press, Bentley House, 200 Euston Road, London, N.W.1. The subscription rates for non-members of the Nutrition Society are £3 per volume of four quarterly parts, and separate parts will cost 20*s*. each.

Royal Society of New Zealand

The Sixth Science Congress under the auspices of the Royal Society of New Zealand was held during the week beginning May 18. This Congress was the first held since the outbreak of war, and it was attended by more than 700 members. In addition to the General Section, there were eleven sections covering practically every department of science; in these sections 220 papers were contributed. Prof. W. N. Benson's presidential address to the Congress was entitled "Scientists Look Toward the Future".

At the annual meeting of the Council of the Royal Society of New Zealand held on May 22, the following officers were elected: *President:* Dr. E. Marsden, secretary to the N.Z. Department of Scientific and Industrial Research; *Vice-President:* Dr. R. A. Falla, director of the Dominion Museum, Wellington. The following were elected fellows of the Society: Dr. M. A. F. Barnett, Government Meteorologist, Wellington; Dr. Ernest Beaglehole, lecturer in psychology, Victoria University College, Wellington; Miss Lucy B. Moore, botanist, Plant Research Bureau, Wellington; and Prof. H. G. Forder, professor of mathematics, Auckland University College, Auckland. The T. K. Sidey Summer-time Medal and Prize were awarded to Dr. D. F. Martyn, Commonwealth Observatory, Mt. Stromlo, Canberra.

Mond Nickel Fellowships

In February 1946, Sir William Griffiths, chairman and managing director, Mond Nickel Co., Ltd., invited the Institute of Metals, the Iron and Steel Institute, the Institution of Mining and Metallurgy, the Institute of British Foundrymen and the Institution of Metallurgists to co-operate with the Mond

Nickel Co., Ltd., in awarding annually for the next fifteen years a number of fellowships, to be known as 'Mond Nickel Fellowships'. The Company offered, to make available over a number of years the sum of £50,000 to be used for awarding these fellowships. Particulars of the fellowships have now been issued. Mond Nickel Fellowships will be awarded to persons of British nationality educated to university degree or similar standard though they need not necessarily be qualified in metallurgy. There are no age limits, though awards will seldom be made to persons more than thirty-five years of age. Each fellowship will occupy one full working year; it is proposed to award up to five fellowships each year of an average value of £750. It is hoped by the aid of these fellowships to enable selected persons to pursue such training as will make them better capable of applying the results of research to the problems and processes of the British metallurgical and metal-using industries, and to increase the number of those who, if they are eventually employed in executive and administrative positions, will be competent to appreciate the technological significance of research and its results. The fellowships will be awarded to selected candidates who wish to undergo a programme of training in industrial establishments and will normally take the form of travelling fellowships; awards for training at universities may, however, be made in special circumstances. Forms of application can be obtained from the Secretary, Mond Nickel Fellowships Committee, 4 Grosvenor Gardens, London, S.W.1. Completed application forms must reach the Secretary of the Committee not later than September 1, 1947.

New York Academy of Medicine: Section on Microbiology

The New York Academy of Medicine has decided to form a Section on Microbiology. This new Section, which brings the number of sections of the Academy to twelve, has for its main objectives the encouragement of the exchange of information among microbiologists, and the promotion of ready contacts between clinical and laboratory investigators. The fellowship of the Section will be broad and will include not only those who have a direct interest in microbiology, but also those who deal with microbiology in their primary functions as clinicians or scientists in other branches. The officers of the newly organised Section are: *Chairman*, Dr. Gregory Shwartzman, Mount Sinai Hospital, New York; *Secretary*, Dr. Harry Most, New York University College of Medicine; *Advisory Committee*, Dr. René J. Dubos, Rockefeller Institute for Medical Research; Dr. Frank L. Horsfall, jun., Rockefeller Institute for Medical Research; Dr. Colin M. MacLeod, New York University College of Medicine; Dr. Ralph S. Muckenfuss, Research Laboratories, New York City Health Department; and Dr. John G. Kidd, Cornell Medical College.

Invention of the Telephone

In connexion with the centenary address on "Alexander Graham Bell and the Invention of the Telephone" given before the Royal Society of Edinburgh by Prof. G. W. O. Howe, an abridgment of which was published in *Nature* of April 5, Capt. G. C. Wilson, 375 McKay Street, Ottawa, has written maintaining that the telephone was invented at Brantford, Ontario, the Canadian home of the Bell family, and not at Boston. In support of this a quotation is given from a letter written by Bell in 1904, saying: "Now it so happens that the telephone was invented in Brantford during my visit to my father and mother in 1874". By 'invention' he probably meant the conception of the idea, for it was in the following February that he visited Henry in Washington and explained to him his idea of an articulate telephone. Henry encouraged him to develop the idea, which he thought might be the germ of a great invention. It was on June 2, 1875, that, while experimenting with the harmonic telegraph in Boston, the slight accident occurred which gave Bell the clue to the solution of the telephone problem, and as his assistant Watson said, "the speaking telephone was born at that moment". Where the invention was made depends on what one means by 'invention'. Bell certainly carried out experiments at his parents' home at Brantford when he was not at Boston; but it is generally agreed that it was in Boston that the experimental development occurred which can be regarded as the birth of the telephone.

Statue of Eros in Piccadilly Circus, London

Apart from its interest to Londoners and its inherent æsthetic merit, the statue of Eros, surmounting the Shaftesbury Memorial Fountain in Piccadilly Circus, London, has a scientific aspect. Originally unveiled in 1893, it is cast in aluminium alloy, the basal structure being of bronze. Its restoration, after a war-time exile, necessitated a thorough cleaning, the repair of a few defects, and the provision of a new bow and arrow. The work was entrusted by the London County Council to Mr. G. Friese Greene, of Messrs. Starkie Gardner, Ltd., of Southfields, craftsmen in metals, since the original makers are no longer in business. The cleaning was carried out with neutral soap and warm water, the surprising discovery being that there is no trace of corrosion arising from the past fifty years in the London atmosphere; with suitable care the original oxide film of the aluminium and the *patina* of the bronze have both been retained. The statue is actually cast in pieces, and the latter are threaded over a steel tree and swaged together, the joints being difficult to find. The hot forging and the cold hammering of the new bow and arrow showed that aluminium alloy can be a very useful metal for sculptors and is actually easier to work than stone. The experience with the restoration of Eros should give an impetus to designers to make more use of these 'modern metals'.

Museum of the History of Science, Oxford

The Museum of the History of Science, Oxford, whose collections, during the war period, were stored in the basement, is reopening on July 2 with an exhibition of historic scientific instruments pertaining to medicine and surgery. The exhibition will include the extremely fine collection of microscopes acquired from Dr. Reginald Clay in 1944 and now for the first time publicly exhibited. The immediate occasion of the exhibition is the meeting of the Association of Surgeons of Great Britain and Ireland and of the International Physiological Congress, both of which will be held in Oxford in July. The exhibition will be held in the School of Natural History, the ground floor room of the Old Ashmolean Building, which has not been open to the public during the past fifty years. There will be a simultaneous exhibition of books and manuscripts illustrating medicine, surgery and physiology in the New Bodleian Library.

Lady Tata Memorial Trust Awards

The Trustees of the Lady Tata Memorial Fund announce that, on the recommendation of the Scientific Advisory Committee in London, they have made awards as follow for research in blood diseases, with special reference to leukæmia, in the academic year beginning on October 1, 1947; the place at which the awards will be used is given in brackets: *Grants for research expenses and assistance:* Dr. Jørgen Bichel (Aarhus); Dr. Pierre Cazal (Montpellier); Dr. Pierre Dustin (Brussels); Dr. Peter A. Gorer (London); Dr. Maurice Guérin (Paris); Dr. Jozef Japa (Cracow); Dr. Edith Paterson (Manchester); Prof. Edoardo Storti (Pavia); Dr. Johannes Clemmesen (Copenhagen); and Dr. Tage Kemp (Copenhagen). *Scholarships (for whole-time or part-time research):* Dr. Simon Iversen (Copenhagen); Dr. C. F. M. Plum (Copenhagen); Dr. G. H. R. Tötterman (mainly in Helsinki).

The Night Sky in July

Full moon occurs on July 3d. 10h. 38m. U.T., and new moon on July 18d. 04h. 15m. The following conjunctions with the moon take place: July 15d. 05h., Mars 0·9° S.; July 26d. 07h., Jupiter 0·2° S. In addition to these conjunctions with the moon, Mercury is in conjunction with Venus on July 22d. 09h., Mercury being 4·9° S. Mercury sets at 21h. at the beginning of July and is too close to the sun for favourable observation. The planet is in conjunction with the sun on July 14, and at the end of the month rises 1h. 20m. before sunrise. Venus is too close to the sun to be observed with advantage, rising about an hour before sunrise during the month. Mars, in the constellation of Taurus, rises at 1h. 30m., 1h. and 0h. 38m. at the beginning, middle and end of the month, respectively, and is a little fainter than a first magnitude star. Jupiter, in the constellation of Libra, can be seen in the earlier portion of the night, stellar magnitude about −2, setting at 1h. on July 1 and at 23h. on July 31. Saturn, in the constellation of Cancer, is too close to the sun for favourable observation, but can be seen for a short time at the beginning of July, when it sets one and a half hours after the sun. Occultations of stars brighter than magnitude 6 are as follows: July 13d. 01h. 44·9m., 31 Aries (*R*); July 27d. 22h. 12·1m., ρ Ophi. *m* (*D*). The latitude of Greenwich is assumed and *R* and *D* refer to reappearance and disappearance respectively. An occultation of Mars occurs on July 15d. 03h. 20·5m., reappearance taking place at 4h. 13·6m. The earth is in aphelion on July 5, its distance from the sun then being slightly more than 94½ million miles.

Announcements

Dr. F. H. S. Curd, Dr. D. G. Davey and Dr. F. L. Rose, of Imperial Chemical Industries, Ltd., have been awarded the Gold Medal in Therapeutics of the Society of Apothecaries in recognition of their work in the preparation of the anti-malarial drug 'Paludrine'.

Mr. D. J. B. Copp, University College, Southampton, has been appointed assistant secretary of the British Association as from July 1.

The following appointments in the University of Leeds have been announced: Mr. G. P. Meredith, lecturer in educational psychology; Mr. H. Stansfield, lecturer in mechanical engineering; Mr. S. Mackey, lecturer in civil engineering; and Dr. E. Mundel, lecturer in electrical engineering.

The following appointments have been made in the University of Sheffield: A. J. Hunt and R. A. G. Savigear, to be assistant lecturers in geography; A. E. Bender and Monica Lindsay, to be assistant lecturers in biochemistry.

The following appointments, promotions and transfers in the Colonial Services have recently been made: H. W. Dougall, agricultural chemist, Sierra Leone/Gambia; N. Lawrence, professional assistant, Royal Observatory, Hong Kong; G. H. Payne, assistant government chemist, Tanganyika; W. J. Blackie (senior chemist, Fiji), deputy director of agriculture, Fiji; H. C. Thorpe (plant breeder, Kenya), senior plant breeder, Kenya; C. E. Duff (senior assistant conservator of forests, Northern Rhodesia), conservator of forests, Northern Rhodesia; R. G. Miller (assistant conservator of forests, Northern Rhodesia), senior assistant conservator of forests, Northern Rhodesia.

Dr. L. S. B. Leakey states that a limited number of excellent casts of the mandible of the Lower Miocene ape *Proconsul* (see *Nature*, **152**, 319; 1942) are now available for distribution, as well as a good cast of the large facial fragment. Those interested should write to the Curator, Coryndon Museum, P.O. Box 658, Nairobi.

The response to the proposal to form a British Herpetological Society has been sufficient to enable further steps to be taken to inaugurate the society. An inaugural meeting will be held at the rooms of the Linnean Society, Burlington House, Piccadilly, London, W.1, on Friday, July 11, at 5 p.m. A report on the proceedings of the meeting will later be published for the benefit of members. All secretarial work in connexion with the formation of the Society is now being undertaken by Mr. Alfred Leutscher, of 5 St. Margaret's Court, London, E.12, as Capt. J. D. Romer is shortly to take up an appointment abroad.

The second annual electronics exhibition, arranged by the Institution of Electronics (North Western Branch), will be held at the Manchester College of Technology on July 22 (2.30–9·0 p.m.) and July 23 (10 a.m.–9 p.m.). Two shows of scientific films will be given each evening. Admission is by ticket obtainable from A. Coates, 16 Didsbury Park, Manchester 20.

We have received from the Murphy Chemical Co., Ltd., of Wheathampstead, Herts, a useful pamphlet of 32 pages on "Insecticides and Fungicides" supplied by them. It includes hints as to the proportions of the spray-mixtures to be used in various cases and a spraying programme for fruit and market garden crops.

Erratum. Dr. C. W. Shoppee has directed attention to the fact that Prof. T. Reichstein and Dr. L. H. Sarett have so far prepared only five of the adrenocortical hormones by partial synthesis, and not six as was stated in the article entitled "The Adrenal Cortex" (*Nature*, June 7, p. 765). The missing one is Reichstein's substance *M*, 17 (α)-hydroxycorticosterone.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications

The Corpus Allatum and the Control of Metamorphosis in Insects

Moulting in *Rhodnius* is initiated by a hormone secreted in the dorsum of the brain, and the premature metamorphosis of the young stages is prevented by a second hormone, the juvenile hormone secreted by the corpus allatum[1-3]. This conception of growth regulation in insects has proved applicable to Orthoptera[4-7], Lepidoptera[8-10] and Coleoptera[11]. In the Diptera, on the other hand, the composite 'ring gland' appears actively to induce metamorphosis, as though it were secreting a metamorphosis-promoting hormone[12].

There is, however, some evidence that the central part of the ring gland, the part representing the corpus allatum, restrains the differentiation of the imaginal disks in the early stages in *Drosophila*[13], and recently Vogt[14] has found that the corpus allatum of the adult *Drosophila* implanted into the larva will cause a local suppression of adult characters.

This last observation implies that the corpus allatum of the adult insect is once more secreting the juvenile hormone. In the grasshopper *Melanoplus*, Pfeiffer[6] has shown that such is the case; and she has even suggested that the yolk-forming hormone of the adult insect may prove to be identical with the juvenile hormone of the young stages.

I have recently found that this is so, apparently, in *Rhodnius*. The corpus allatum of the adult *Rhodnius*, implanted into a 5th stage nymph, causes it to develop into a giant 6th stage nymph; and the secretion from the corpus allatum of the 4th stage nymph will induce egg production in the decapitated adult female.

I have found also that there is a second factor in metamorphosis. The corpus allatum of the moulting 5th stage nymph in *Rhodnius* not only ceases to secrete the juvenile hormone, but also it actively removes from the blood any traces of the juvenile hormone that remain. The decapitated 4th stage nymph exposed to the moulting hormone from the 5th stage nymph undergoes a precocious metamorphosis; but the adult characters are differentiated more completely if the 5th stage nymph retains its corpus allatum. The corpus allatum of the 5th stage nymph in the late stages of moulting or of the newly moulted adult, implanted into intact 3rd or 4th stage nymphs, reduces the activity of the juvenile hormone so that when they reach the 5th stage some of them show a partial metamorphosis (Figs. 1 and 2).

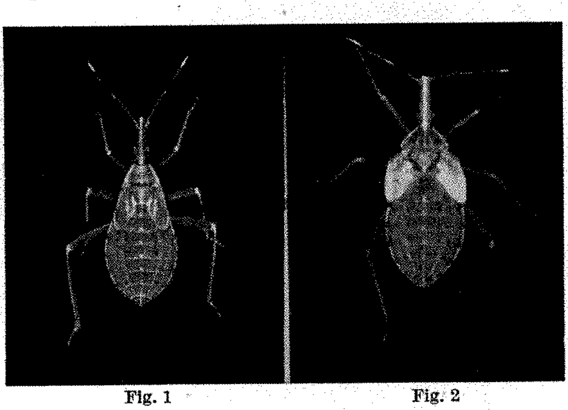

Fig. 1 Fig. 2

Fig. 1. Normal 5th stage nymph

Fig. 2. 5th stage nymph following implantation of corpus allatum of young adult into the 3rd stage, showing partial metamorphosis

This effect is always diffused throughout the body; it is never localized in the region of the implant, as the effect of the juvenile hormone often is. It is unlikely, therefore, that it is due to the secretion of an imaginal or metamorphosis hormone.

I suggest that it may be the active elimination of juvenile hormone in the Diptera which creates the impression of a 'metamorphosis-promoting hormone'. If it be supposed that these two factors, the cessation of secretion of the juvenile hormone and the active elimination of this hormone, differ in their relative importance in different insects, we may perhaps have the basis for a theory of metamorphosis which will be applicable to all groups of insects.

Evolutionary Significance of Periodicity of Variation-Intensity and Population-Flux in the Desert Locust

The periodic mass-increase in the population of the desert locust, *Schistocerca gregaria* (Forskål), which ranges from Africa to India, is a phenomenon known since Biblical times. The compilation of historical records of the last century and a half has established an *average* 11-year cycle of mass-increase, although the individual periods are far less regular. Following Uvarov's work[1,2], the existence of two phases, namely, the swarming or *gregaria* phase and the non-swarming or *solitaria* phase, has also been established. These phases differ morphologically and in other ways, are connected by a graded series of intermediates, and are evidently of no genetical significance; they can be produced at will by the simple process of crowding and thinning.

The last cycle of increase lasted from about 1926 until 1931, followed by a *solitaria* period of several years. We are now in the middle of another cycle which started in 1940. As a result of considerable work in various countries during the last fifteen years, we now possess a fairly comprehensive knowledge of the migrations and population-flux of this species. Briefly, the species in *solitaria*-years is confined to certain desert tracts extending from West Africa via the Red Sea coast to the Persian coast and Western India, including Rajputana; the population is low, usually not exceeding about 1,000 per sq. mile, and often much less. In *gregaria*-years the population increases enormously (considerably more than 10,000 per sq. mile) and the range also increases, the species spreading to Southern Europe (extending even to

Great Britain in some years), Transcaucasia, Central Asia, Peninsular India and Eastern India (Assam).

I have already shown that during the *solitaria* phase the species is polymorphic in regard to the number of eye-stripes, the wild populations consisting of two main types (6- and 7-eye-striped), with 8-striped forms turning up occasionally in extreme *solitaria*-years (1936–38). During the *gregaria* period, that is, in swarms, *only* 6-striped individuals occur, and the eyes are more heavily pigmented. Occasionally, 5-striped individuals occur in laboratory rearings, evidently as mutants, but such individuals have not yet been found wild. I have elucidated[3,4] the pigmentary basis of stripe formation and their development. The eye-stripe polymorphism is partially correlated with the number of moults[4] and also with the number of antennal segments[5]. In addition to and superimposed upon these variations, two types of colour variations occur in the *solitaria* phase: the majority of wild individuals (91 per cent) are blue-grey as adults and green as hoppers, while the remainder are fawn as adults and buff as hoppers[6,7].

The eye-stripe polymorphism was noted in India and North Africa during the *solitaria* period of 1932–39. It was absent during the past swarming periods, as judged from the examination of museum specimens. During the present swarming cycle (1940–) the polymorphism has again practically disappeared, only a few 7-striped forms being found in North-West India during 1940–46 *after* the main swarms had left; no 8-striped forms have yet been found (Y. R. Rao, *in litteris*).

From the foregoing account, the following important conclusions emerge: (i) The population fluctuates periodically, the 'plague period' of high numbers corresponding with a considerable increase of range of the species. (ii) As regards variation intensity, the species is comparatively stable during the plague or *gregaria* period but highly polymorphic during the *solitaria* period when the population is low. (iii) The phenomenon is periodic and evidently occurs over a wide range (India to Africa) more or less simultaneously. (iv) It would appear that the 7- and 8-striped individuals, which make their appearance during *solitaria* periods when selection-pressure is low probably owing to reduced numbers, are eliminated, presumably by selection, during the *gregaria* periods of high population and increased selection-pressure.

Crossing results show that 6-striped individuals produce both 6- and 7-striped forms in F_1 and F_2 generations. Other results need not be discussed here for the present.

The evolutionary consequences of these phenomena lie in the fact that we have here probably the first clear case of the Wright – Dubinin effect (of random or automatic increase of variation intensity in small, partially isolated populations; random 'drift' of Wright[8]; genetico-automatic processes of Dubinin[9]) in natural populations showing periodic fluctuations. As, fortunately, the periods are small (average eleven years), it is possible to test the results repeatedly and even calculate the rate of flow of a particular variation in Nature[10].

It is interesting that the opposite effect, namely, an increase of variation intensity with increased abundance, is also known to occur[11-13], and Fisher has even provided the mathematical basis of it. The question whether these two opposite effects are due either to totally different mechanisms, or are merely the different expressions of fundamentally the same mechanism, cannot be discussed here, but must be borne in mind. The Hagedoorn effect[14] of steady random (automatic) decay of variation intensity in the total absence of selection has not been demonstrated in Nature; it has been criticized on mathematical grounds by Fisher as being too slow to be ever of any significance in evolution.

A fuller account will be published elsewhere.

A Tubal Factor Concerned in the Denudation of Rabbit Ova

McClean and Rowlands[1] found that hyaluronidases from several sources were able to liquefy the viscous gel cementing the follicle cells around freshly ovulated rat ova, thereby denuding the latter. This was confirmed by Fekete and Duran-Reynals[2] for the mouse and by Leonard and Kurzrok[3] for the rat. On the basis of their observations, McClean and Rowlands suggested that the gel consisted of hyaluronic acid, and that the function of seminal hyaluronidase was to bring about denudation of the egg prior to fertilization. Pincus[4] had noticed that although rabbit cumuli placed in rabbit sperm suspensions underwent rapid disintegration, quite frequently a layer of more densely packed follicle cells (corona radiata) remained surrounding the egg. On the other hand, when this action took place inside the Fallopian tube, the ova became completely denuded within 1½–3 hours of ovulation if insemination had previously occurred, or within 6–8 hours if the mating had been with a vasectomized buck.

Since, in an investigation of the action of hyaluronidase on rabbit cumuli *in vitro*, it had been observed that the corona radiata appeared invariably to remain intact, it was decided to study more closely what part was played by the Fallopian tube in bringing about complete denudation of rabbits' ova.

Female Dutch rabbits were injected intravenously each with 50 I.U. of chorionic gonadotrophin to induce ovulation. Twelve hours later they were killed by air embolism and the Fallopian tubes were removed and washed through with physiological saline to recover the ova, which, in these circumstances, were always embedded within cumuli. The cumuli were placed in fresh saline to remove any material that might have been washed from the tubes, and divided so as to contain two ova each. The portions of cumulus were then placed in separate cells in the minimum amount of fluid. Two ejaculates of rabbit semen were suspended in 20 ml. of Baker's solution[5],

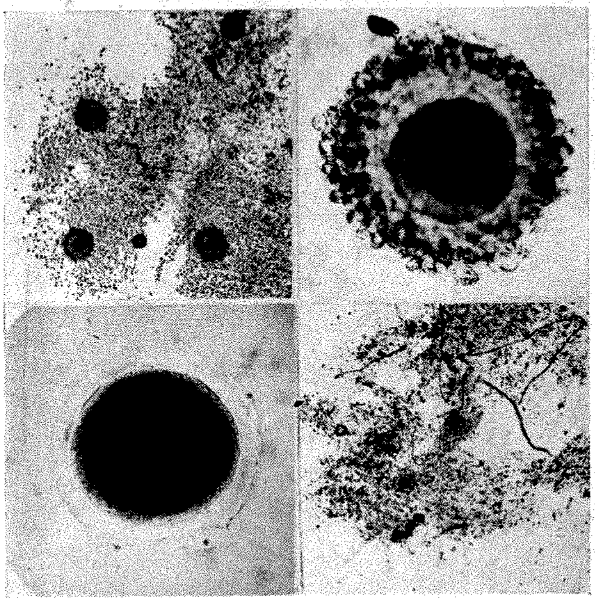

Fig. 1. UNTREATED CUMULUS CONTAINING THREE OVA. (× 15)

Fig. 2. OVUM SURROUNDED BY CORONA RADIATA, AFTER ACTION OF HYALURONIDASE ON CUMULUS. (× 145)

Fig. 3. COMPLETELY DENUDED OVUM, RECOVERED FROM FALLOPIAN TUBE INTO WHICH IT HAD BEEN INSERTED WHILE IN THE CONDITION SHOWN IN FIG. 2. (× 145)

Fig. 4. CUMULUS CONTAINING TWO OVA, RECOVERED FROM FALLOPIAN TUBE INTO WHICH IT HAD BEEN INSERTED WHILE IN THE CONDITION SHOWN IN FIG. 1. (× 15)

the suspension then being divided into two portions both of which were centrifuged for 10 min. The supernatant from one portion (*A*) was removed and fresh Baker's solution added to the original level, the sperms being stirred up. The sperms in the second portion (*B*) were stirred up in their original supernatant. 0·2 ml. aliquots of the three fluids (*A*, *A* supernatant, and *B*), the sperms being fully active in *A* and *B*, were then added to the cumuli in their cells, each fluid being added to two cumuli. The times required to free the eggs from their cumuli are shown in the table.

Fluid	Time required to free ova (min.)	Average time (min.)
A	21	26
A	31	
A supernatant	20	
A supernatant	26	23
B	20	20
B	20	

In all the above the coronæ remained intact, and it is clear that the presence of spermatozoa is unnecessary for disintegrating the cumulus, hyaluronidase in solution being adequate for the purpose. Thirty hours later the coronæ were still intact. The addition of a tubal extract, made by grinding two Fallopian tubes with sand, extracting with saline and filtering, was also without effect on the corona, neither did the addition of 10 units of standard freeze-dried bull semen filtrate (Swyer and Emmens[6]) produce any effect within 1½ hours.

In the next series of experiments, cumuli were obtained as before from three rabbits, some being placed in a solution consisting of 10 units of hyaluronidase (bull) in 2 ml. saline which freed the eggs within 10 min., leaving the coronæ intact. Under ether anæsthesia the abdomen was opened in three other rabbits, and three or four eggs treated as above were inserted into the fimbriated end of one tube while an untreated cumulus was inserted into the other in each rabbit. The wounds were closed in the usual way. Three hours later the rabbits were killed, the tubes washed out and the eggs recovered. The cumuli which had been inserted intact were recovered intact, while the treated eggs were recovered either completely denuded or with only a few adherent follicle cells (Figs. 1–4).

It is clear, therefore, from these results that disintegration of the corona radiata of the rabbit's ovum is effected, not by the action of hyaluronidase, but by some influence exerted by the Fallopian tube. This influence comes into play after the cumulus has been removed, ordinarily by the action of hyaluronidase, but in the absence of insemination, by the much slower action of the tube itself, as shown by the time relations established by Pincus. The nature of the tubal factor is not clear at present; the fact that tubal extracts are without action on the corona or cumulus would seem to rule out a purely chemical effect, and perhaps suggest a mainly mechanical one dependent, for example, on ciliary action and muscular contraction. Attempts at demonstrating such an action have been made by inserting hyaluronidase-treated ova into the tubes of pseudo-pregnant rabbits (in which tubal activity, as a result of the influence of progesterone, might be considered as diminished) and also by instilling 0·2 per cent procaine along with the treated ova into the tubes of normal rabbits. In all these experiments the recovered ova were denuded of their coronæ, so that no conclusions could be drawn from them.

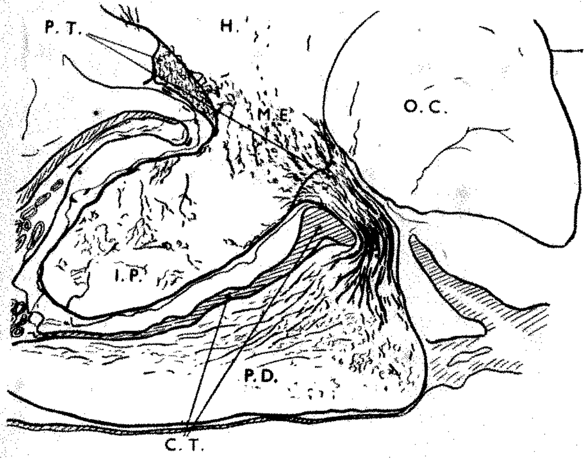
The Hypophysial Portal Vessels of the Porpoise (*Phocæna phocæna*)

IF the nervous system influences the activity of the anterior lobe of the pituitary gland by liberating some humoral excitant into the hypophysial portal vessels, which in turn transmit the substance to the gland[1,2], then it would seem likely that these portal vessels would be widely distributed among the vertebrates. It is well known that in birds and some mammals (whale, sea-cow, Indian elephant, armadillo and porpoise) the neural lobe of the pituitary is separated from the pars distalis of the anterior lobe by a connective tissue septum, and it seemed possible that this septum might interrupt the path of the portal vessels in these animals.

To investigate this possibility a male porpoise (*Phocæna phocæna*) weighing 136 lb., and 5 ft. in length, was injected in a cranial direction through the vertebral arteries with India ink. After completing fixation, the hypothalamus, pituitary and surrounding structures were taken *en bloc*, serially sectioned in a sagittal plane at 150 μ, and the sections stained with Biebrich scarlet. The sections show clearly that the porpoise possesses a hypophysial portal system of blood vessels similar to that of other mammals. The pars tuberalis extends upwards to embrace the tuber cinereum as a ring-like collar. The portal vessels start as the characteristic sinusoidal



MID-LINE SAGITTAL SECTION THROUGH THE HYPOTHALAMUS AND PITUITARY GLAND OF A PORPOISE. VESSELS INJECTED WITH INDIA INK. CAMERA LUCIDA DRAWING. × 9·3

C.T., connective tissue septum, derived from the dural capsule of the gland, intervening between the infundibular process and the pars distalis; *H.*, hypothalamus; *I.P.*, infundibular process; *M.E.*, median eminence containing the characteristic vascular loops and tufts; *O.C.*, optic chiasma; *P.D.*, pars distalis; *P.T.*, pars tuberalis

loops in the median eminence, drain into the vascular plexus of the pars tuberalis, where they unite to form the widely dilated trunks which pass ventrally into the sinusoids of the pars distalis. The detailed arrangement is very similar to that of the rabbit, in that the trunks of the vessels are contained in a thick pillar of cells (termed the zona tuberalis in the rabbit[3]), which passes through the diaphragma sellæ by a foramen separate from that transmitting the infundibular stem.

Thus the pituitary gland of the porpoise, in spite of the septum intervening between the two lobes, conforms with that of other mammals in possessing the typical vascular connexions between the median eminence and pars distalis. It is of interest that Drager[4,5] finds the pars distalis of the bird and porpoise to be free of nerve fibres.

I wish to thank Mr. D. A. Parry, Department of Zoology, Cambridge, for the porpoise.

Cytosiderosis and the Genesis of Arteriosclerosis and other Fibrous-Tissue Reactions

CYTOSIDEROSIS is a diffuse metabolic disorder characterized by the deposition of large quantities of iron pigment, at first mainly in the liver and later in other organs and tissues of the body[1,2]. It occurs consistently in adult pellagrins, although it is commonly seen also in other members of the African population not suffering overtly from acute episodes of malnutrition[3].

Serial liver biopsies of the same pellagrin have revealed that the iron pigment is lodged first in the hepatic parenchyma and then later in the reticulo-endothelial system in the liver. By piecing together the evidence derived from our biochemical and pathological studies, we were able to show that the second stage of the disease is characterized by a true siderosis whereby the iron pigment is steadily disseminated via the gut mesenteric glands into the thoracic duct and eventually by the blood circulation[4]. The absorption of such large molecules presupposes a disturbance in digestion and in the absorptive capacity of the gut epithelium.

Obstruction to the pancreatic duct of cats fed a particular diet containing large quantities of iron over a period of time results in the appearance of excessive amounts of iron in the liver[5,6]. This was attributed to a vitamin A deficiency which impaired the absorptive efficiency of the gut epithelium[6]. Our own investigations in cats have shown that when the pancreatic ducts are tied, iron can still appear in the liver when vitamin A is being actively absorbed. Severance of the pancreatic duct and a high iron-containing diet greatly expedite this extraordinary disturbance in iron metabolism in cats. Normal cats fed the same diet only develop an iron flush in the Kupffer cells, whereas, over the same period of time, cats with obstructed pancreatic ducts accumulate massive quantities of iron pigment in the liver. From these experiments in cats, it is evident that a badly balanced diet can lead to the accumulation of iron-containing molecules in the reticulo-endothelial system.

It has been shown in our laboratory that the pigment in human cytosiderosis is a relatively inert molecule. The intravenous injection of this pigment into normal cats results in the accumulation of large masses of pigment, at first in the reticulo-endothelial system in the form of coarse clumps, and later in the liver cells situated near the medium-sized portal tracts, such as we have described in the second stage of cytosiderosis in African pellagrins. Injection of colloidal iron in amounts equivalent to the iron present in the pigment over the same period leads only to a slight flushing of the Kupffer cells similar to that noted in intact cats fed the equivalent of approximately 40 mgm. of iron per diem.

Whether or not the second stage of cytosiderosis in the African is associated in particular with a disorder of the pancreas is not of immediate consequence, although we have shown that in malnourished infants the early stages in the genesis of cystic fibrosis can be detected. The important issue, so far as this communication is concerned, resides in the observation that sooner or later in cytosiderosis an inert molecule first found intracellularly in the liver is excreted via the bile, then absorbed by the gut and disseminated by the systemic circulation. The flooding of the circulation with macromolecules can result in a number of extraordinary reactions constituting the macromolecular syndrome[7]. The noteworthy features of this syndrome are the production of arteriosclerosis, fibrosis of the spleen and curious hæmatological reactions. While the experiments conducted on the macromolecular syndrome by Hueper and others were mainly of an acute character, nevertheless the conclusions are unequivocal.

If now it is remembered that cytosiderosis in the African occurs very frequently in the third, and can be very extensive in the fourth decade, it is evident that a large, inert, iron-containing molecule is steadily flooding the circulation in minute amounts for ten to fifteen years. Such a state of affairs could quite easily lead to those conditions optimum for the development of premature arteriosclerosis and other instabilities of the cardiovascular system known to occur in young Africans[8,9], in addition to cirrhosis of the liver, the tendency to keloids[10], reticulosis, etc. For such reactions to occur, it would appear that chronic malnutrition associated with disease of the liver and the pancreas might also be essential attributes of the background of the African.

While in African pellagrins we were able to track the movements of the macromolecule by virtue of its iron-containing fraction, it is also very likely that other types of macromolecules—protein, polysaccharides, lipoproteins and the like—may enter the circulation in conditions similar to those described for cytosiderosis. A new approach is now available for attacking the several problems connected with the tendency to fibrous tissue reactions noted in many metabolic disorders, and expressed as arteriosclerosis, hypertension, reticulosis and cirrhosis. Investigations are proceeding actively in this laboratory to elucidate this and other aspects of the problem.

Hydrochloric Acid Formation in the Gastric Mucosa

IN a recent article[1] concerning the mechanism of high acid production by bakers' yeast and its bearing on hydrochloric acid formation in the stomach, reference was made by us to the work of Davies *et al.*[2,3] on the respiratory exchange and hydrochloric acid production by the gastric mucosa of the frog. It was pointed out that though such results appear of value for the theory of formation of hydrochloric acid, they in no way disprove the *essentials* of the theory proposed from our Department as to the manner of formation of the acid[4]. After reading the recent communication of Davies *et al.*[5], we can only reaffirm our conclusions in this respect concerning their data.

In their communication, and referring presumably to their findings that the maximum Q_{HCl} is twice the maximum Q_{O_2} for the isolated gastric mucosæ, they say that these "facts rule out theories dependent on the production of hydrogen ions by the fermentation or oxidative degradation of any carbon compound". Also, they write that a statement of ours to the effect that a cyclical process (with H ions deriving from an organic acid) could give a Q_{HCl} far higher than Q_{O_2} "is not justified".

Both these statements of Davies *et al.*[5] may be shown to be incorrect, as indicated in the accompanying cyclical scheme. In this the hydrogen ions are assumed to come from phosphoglyceric acid, produced by the dehydrogenation of triosephosphate; but, *it is to be understood that this reaction is chosen only for illustration*, and that some other reaction, or indeed several reactions, involving acidic production may be operative. The scheme is presented in stages which are numbered for convenience of reference. Some obvious connecting links have been omitted. For ease of presentation, single molecules or ions appearing in the reactions or exchanges have been given.

In the scheme, fluid containing potassium chloride in strength approximately isotonic with blood is excreted in a special region and flows past the acid region, potassium ions being exchanged for hydrogen ions. The hydrogen atoms which wander from the triosephosphate are received by an acceptor, but are not further transferred in this region of the cell to molecular oxygen.

In the fifth stage, the reversal of the dehydrogenation occurs—in another part of the cell—hydrogen ions now disappearing from solution and an alkalinity corresponding to the acid secreted being produced. In stage 6, the view of Davies *et al.*[5] that carbon dioxide *from the blood* neutralizes the hydroxyl ions and forms HCO_3 ions (passing via H_2CO_3, the formation of the carbonic acid being catalysed by carbonic anhydrase), is included, as this appears now to interpret well the final exchanges; but, as stated in our article[1], any view assuming carbonic anhydrase to act at the immediate site of the acidic formation would appear improbable. In stage 7, HCO_3 ions exchange for chlorine ions across the membrane.

A cyclical scheme of the above type could also be developed for other views such as those of Bull and Gray[6], which turn on the formation of an organic acid; and it would appear, too, that carbonic acid as a source of hydrogen ions could be similarly developed. The scheme presented is perhaps best described as a working hypothesis (and present views of hydrochloric acid formation in the stomach can be regarded as little more), but its most essential feature can be illustrated by the biological model of bakers' yeast working under certain conditions and producing a high degree of acidity.

Considering now the quotient $Q_{\text{HCl}}/Q_{\text{O}_2}$ which could result from such a scheme, it will be assumed for illustration that the phosphoglyceraldehyde and phosphoglycerate are shifted from a 9 : 1 to a 1 : 9 ratio (and then restored to the former ratio), and that for both conditions the equation :

CYCLICAL SCHEME FOR THE PRODUCTION OF HYDROCHLORIC ACID

	Lumen	Intracellular substance		Blood or inter-cellular spaces
1.		$R.\text{CHO} + \overset{+}{\text{K}} + \overset{-}{\text{Cl}} + \text{Ac}$		$\overset{-}{\text{Cl}} + \text{CO}_2 + \text{H}_2\text{O}$
2.	$\overset{+}{\text{K}} + \overset{-}{\text{Cl}}$	$R.\text{CHO} + \text{Ac}$		$\overset{-}{\text{Cl}} + \text{CO}_2 + \text{H}_2\text{O}$
3.	$\overset{+}{\text{K}} + \overset{-}{\text{Cl}}$	$\overset{+}{\text{H}} + R.\overset{-}{\text{COO}} + \text{AcH}_2$		$\overset{-}{\text{Cl}} + \text{CO}_2 + \text{H}_2\text{O}$
4.	$\overset{+}{\text{H}} + \overset{-}{\text{Cl}}$	$\overset{+}{\text{K}} + R.\overset{-}{\text{COO}} + \text{AcH}_2$		$\overset{-}{\text{Cl}} + \text{CO}_2 + \text{H}_2\text{O}$
5.	$\overset{+}{\text{H}} + \overset{-}{\text{Cl}}$		$R.\text{CHO} + \overset{+}{\text{K}} + \overset{-}{\text{OH}} + \text{Ac}$	$\overset{-}{\text{Cl}} + \text{CO}_2 + \text{H}_2\text{O}$
6.	$\overset{+}{\text{H}} + \overset{-}{\text{Cl}}$		$R.\text{CHO} + \overset{+}{\text{K}} + \overset{-}{\text{HCO}_3} + \text{Ac}$	$\overset{-}{\text{Cl}}$
7.	$\overset{+}{\text{H}} + \overset{-}{\text{Cl}}$		$R.\text{CHO} + \overset{+}{\text{K}} + \overset{-}{\text{Cl}} + \text{Ac}$	$\overset{-}{\text{HCO}_3}$

$$E_h = E'_0 - \frac{RT}{nF} \ln (\text{Red.})/(\text{Ox.})$$

applies with the same E'_0 value; then the free energy requirement per equivalent of hydrogen ions produced, to restore the condition as in the scheme, is approximately 1,700 cal., the free energy change per mol. oxygen used in oxidizing carbohydrate being about seventy times this value[7]. For the interpretation of the Q_{HCl}/Q_{O_2} values found by Davies *et al.*[5], this allows a very wide latitude for efficiency considerations, etc.

The views of Davies *et al.*[8,5] with respect to electric force playing an important part in the elaboration of hydrochloric acid, by way of splitting water molecules, we find unsatisfactory chiefly for the following reasons: (1) Their hypothesis appears to arise mainly from the mistaken view that the facts of the respiratory exchange preclude an explanation from the formation of hydrogen ions by organic acid. (2) No indication is given as to the manner in which such electric power operates. Other objections could be also advanced.

We regret having misinterpreted a statement in one of the summaries of Davies[3]. From evidence at our disposal, we concluded that Q_{HCl}/Q_{O_2} figures greater than 2·0 had been obtained, so that the sentence "In bicarbonate saline the Q_{HCl} sometimes rose to twice the Q_{O_2} without causing visible damage to the tissue" seemed to imply that beyond a Q_{HCl}/Q_{O_2} of twice, the tissue was damaged. We are glad that this point has been cleared up (but for the general theoretical interpretation it is of minor significance); and also that a printer's error in our article has now been corrected by Davies *et al.*[5].

Volume Change Accompanying the Splitting of Ribonucleic Acid by Ribonuclease

A PREVIOUS investigation by Linderstrøm-Lang and Jacobsen[1] has shown that dilatometric measurements can be useful in the study of the enzymatic breakdown of macro-molecules. Thus it was found that the contraction accompanying the tryptic and chymotryptic splitting of lactoglobulin was too great to be compatible with the assumption that the degradation of this protein is exclusively caused by an opening of peptide bonds in a rolled-up peptide chain. A recent extension of these experiments to include other proteins has made it likely that this phenomenon is common to the molecules of globular proteins, and that it is the breakdown of the superstructure of these molecules that causes the abnormal contraction.

We have thought it of interest, in analogy with these investigations, to study the breakdown of another type of macro-molecule, the nucleic acids. We have chosen ribonucleic acid because one of the authors (Chantrenne) was familiar with this substance from previous work. The particular ribonucleic acid preparation used was made according to Chantrenne (ref. 2, fraction A), but from Danish bakers' yeast. The product obtained was somewhat different from that previously described[2], and we therefore give the titration curves (Fig. 1) for the Danish nucleic acid before and after degradation with ribonuclease (prepared according to Kunitz[3]).

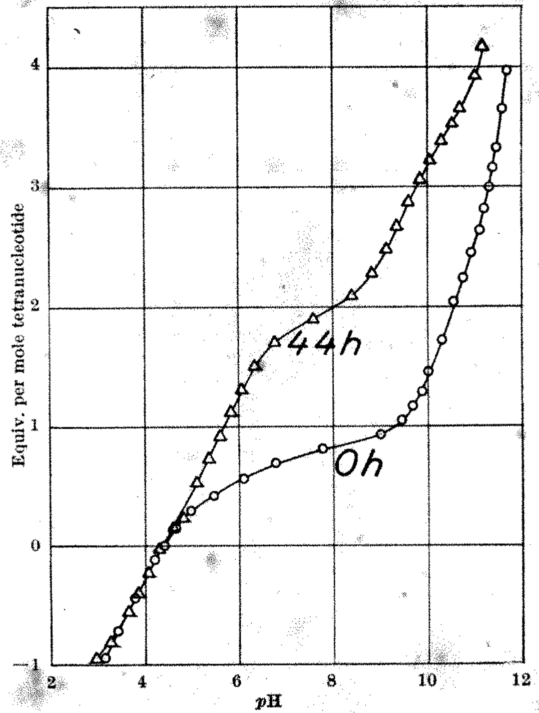

Fig. 1

It will be observed that the change in pH caused by the action of ribonuclease is negligible around pH 4·6 and below, and we can, therefore, feel confident that the volume change observed during an enzymatic process at this pH does not originate in an interchange of protons between the nucleic acid and the medium.

The following experiments may serve as an example of our results. *Enzymatic system.* Sodium salt of ribonucleic acid 1 per cent, pH 4·6, sodium chloride 0·1 N, ribonuclease 0·0125 and 0·005 per cent (curves I and II respectively), $T = 30°$. Dilatometric technique as described in ref. 1, but reduced to micro scale. *Determination of the opening of phosphate bonds:* microtitration with sodium hydroxide, end-point pH 8, indicator cresol red. Due to the continued action of ribonuclease at the end-point, extrapolation to zero titration time was made by means of titration-time curves.

The results are seen in Figs. 2 and 3. ΔP denotes the number of phosphate bonds opened, ΔV the volume change. The data are calculated as ml. and equivalents per mole tetranucleotide.

It will appear from the graphs that our results are compatible with earlier work on the action of ribonuclease[4-7], namely, that this enzyme has two functions, one as a 'depolymerase' or 'denaturase' and the other as a 'phosphatase'. In its first capacity it acts very rapidly, presumably preparing the nucleic acid molecule for the slower attack by the phos-

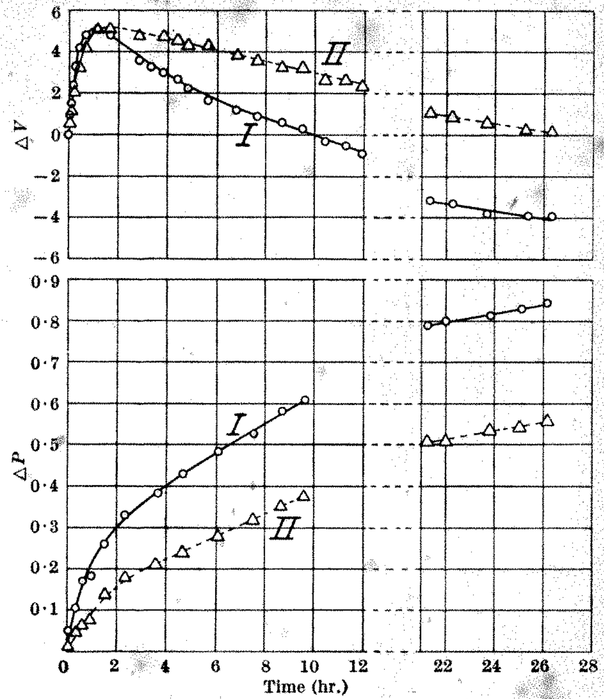

Fig. 2

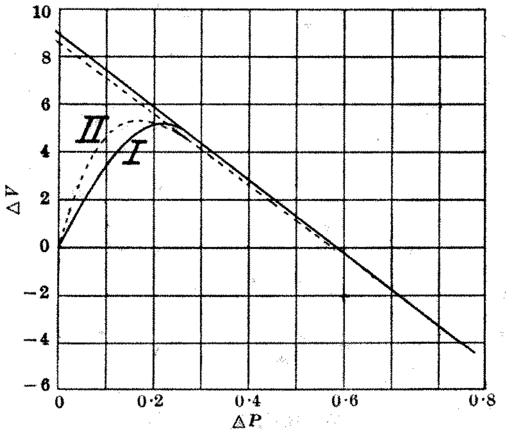

Fig. 3

phatase which breaks the molecule down to tetranucleotides. The 'depolymerization' is accompanied by an increase, the splitting of the phosphate linkages by a decrease, in volume. If we consider the right-hand part of the curves in Fig. 3, where the cleavage of the phosphate linkages is predominant, we observe that they are straight lines with a slope $\Delta V/\Delta P$ of about − 13 ml./equiv. Assuming now that this relation holds true for the phosphate-bond cleavage during the entire enzymatic process, we obtain the total volume increase due to 'depolymerization' by extending the lines until they intersect the axis of ordinates. In this way we find a value of 8–9 ml. per mole tetranucleotide, or about one per cent of the nucleic acid molecule. We shall not discuss the significance of this rather hypothetical value here, but we would like to point out the similarity of the problem to that met with in the case of proteins. In both cases an initial process involving a breakdown of some superstructure seems to be required before the 'true' chemical degradation can set in. We cannot offer any satisfactory explanation why this process is accompanied by a contraction of the protein and a dilatation of the nucleic acid, but we are willing to follow Gulland and his collaborators in assuming that some kind of 'physical' bond between the purines and pyrimidines is present and put out of action in the latter case. The possibility of resonance is considerable in these substances. But it must be borne in mind that the opening of bonds involving ionogen groups (see ref. 8) is unlikely, due to the constancy of pH.

Finally, we would point out that the value $\Delta V/\Delta P = -13$ is surprisingly high for the splitting of an ester bond when, as in the present case, the hydroxyl group belonging to the phosphoric acid remains uncharged. In the splitting of glycerophosphate by acid phosphatase at pH 4·6, the corresponding value is about − 3 ml./equiv. This question requires further investigation.

Effect of Ultra-Filtration and Carbon Dioxide on the Prothrombin Activity of Plasma

It is well known that the prothrombin in plasma is easily susceptible to inactivation, but the nature of the factors responsible for this inactivation has not been clearly understood. M. Gerendas[1] has stated that the inactivation of thrombin is due to two parallel and separate causes, namely, adsorption, and a fermentative inactivating process.

Investigations carried out in this laboratory on the nature of the factors responsible for the inactivation of plasma prothrombin have shown that the prothrombin activity of plasma which has been inactivated on keeping can be regained either by ultra-filtration or by passing carbon dioxide through the plasma; hence it is reversible. However, if the plasma is stored for a longer period (more than a week), the prothrombin undergoes irreversible inactivation, and in such cases neither ultra-filtration nor carbon dioxide has any effect. It should be noted, however, that neither carbon dioxide nor ultra-filtration has any effect on the prothrombin activity of fresh plasma. We have also observed that in the case of inactivated plasma, on adding the ultra-filtrate to the ultra-filtered plasma, the prothrombin is inactivated. These experiments clearly show that the inactivation of prothrombin is due to the presence or formation of substances which can be removed by ultra-filtration.

While studying the prothrombin activity in pathological conditions, such as tuberculosis and jaundice, we found that the low prothrombin activity in such cases can invariably be increased by ultra-filtration or by passing carbon dioxide through the plasma.

In the following table are given some of the typical results of our experiments.

Coagulation time (in sec.)

Plasma	Original plasma	After ultra-filtration	After passing CO_2 for 30 sec.	Prothrombin activity of 0·2 c.c. ultra-filtered plasma + 0·2 c.c. thrombo-plastin	
				+0·2 c.c. water	+0·2 c.c. ultra-filtrate
Bovine plasma					
Fresh	14	—	14	—	—
	19	—	19	—	—
After 24 hr.	30	22	20	—	—
After 48 hr.	28	20	—	21	51
After 72 hr.	42	24	—	27	64
Human plasma (normal)					
Fresh	12	—	13	—	—
After 5 hr.	44	17	—	20	28
Human plasma (pathological)					
Jaundice					
Fresh	15	—	10	—	—
Tuberculosis					
(*a*) Pulmonary					
Fresh	21	—	—	—	—
After 8 hr.	35	20	14	25	32
Fresh	No clotting until 420 sec.	—	46	—	—
After 4 hr.	,,	17	47	—	—
Fresh	17	—	13	—	—
After 3 hr.	25	—	13	—	—
(*b*) Miliary	No clotting until 600 sec.	—	105	—	—

These results show an interesting parallelism between the effect of ultra-filtration and carbon dioxide on the prothrombin activity of plasma.

The mechanism of the effect of carbon dioxide on prothrombin activity of plasma is under investigation.

Our thanks are due to Prof. V. Subrahmanyan for his interest in these investigations.

Influence of Cations in the Production of Citric Acid by Yeast

Succinic and citric acids were found by Wieland and Sonderhoff[1] to be products of the dissimilation of acetic acid by yeast under aerobic conditions. But whereas succinic acid was always obtained in a yield of 5 per cent, the yield of citric acid varied; it amounted to 10 per cent only when they used barium acetate.

Sonderhoff and Deffner[2] re-investigated the production of citric acid in a more systematic manner. They found a yield of 25 per cent under certain conditions by using barium acetate. They suggested, therefore, that this yield of citric acid could be explained by the insolubility of barium citrate. The insoluble barium citrate remains unaffected while sodium citrate, which is very soluble in water, can be easily oxidized further; and it is then easy to understand why traces only of citric acid are found by oxidizing sodium acetate.

Virtanen and Sundman[3] indicated that production of citric acid takes place by oxidizing magnesium acetate, although magnesium citrate is soluble in water. They did not give a complete explanation, but they assumed that magnesium and barium probably have an influence at some stage in the formation of citric acid.

In a series of experiments, we were able to demonstrate that by using cations forming easily soluble citric salts (sodium, potassium and lithium), almost no citric acid was found. We think that the citric salts of these cations can pass easily through the cell wall, and they are dissimilated in the interior. In presence of cations forming insoluble salts (lanthanum, barium and strontium) we obtained a yield of roughly 15 per cent citric acid, because the insoluble citric salts cannot penetrate to the interior of the cell.

In the case of magnesium we found that complex salts are formed. The complex anions have a big volume and they cannot pass through the cell wall. In the case of barium citrate, difficulty in penetrating the cell wall is due to the insolubility of the salt; in the case of magnesium citrate to formation of a complex.

By using ordinary yeast, we found that the citric salts of sodium and potassium are easily dissimilated; those of magnesium and barium scarcely at all. By treating yeast with liquid air[4] and thus destroying the cell wall, we found equal dissimilation of sodium, magnesium, calcium and barium citrates. However, by this method of using yeast with destroyed cell wall, we were not able to oxidize acetic salts.

A detailed account of the experiments will be published elsewhere as soon as the investigation is completed.

Slow Cosmic Ray Mesons at Sea-Level

During the latter part of 1938, a high-pressure cloud chamber designed by the late Prof. E. J. Williams was constructed to investigate certain phenomena concerned with cosmic ray mesons. It was hoped that by using high pressures, giving a long sensitive-time, that mesons would be observed coming to the end of their range in the cloud chamber. Four such examples have been obtained[1]. A similar example was also found by E. J. Williams and G. E. Roberts using a large cloud chamber working at atmospheric pressure[2]. In each case, the meson is observed to come to rest and then to decay with the emission of a β-particle. From these results, it is estimated that the proportion of slow mesons ($\beta < 0{\cdot}25$) in cosmic radiation at sea-level is about 0·05 per cent. In these experiments, no evidence has been found of the disintegration of nuclei by mesons as reported recently by D. H. Perkins[3], and by C. F. Powell and G. P. S. Occhialini[4]. Little information concerning the frequency of such events at sea-level is available, and it was thought that it would be worth while to expose some photographic emulsions in the same room as the cloud chamber.

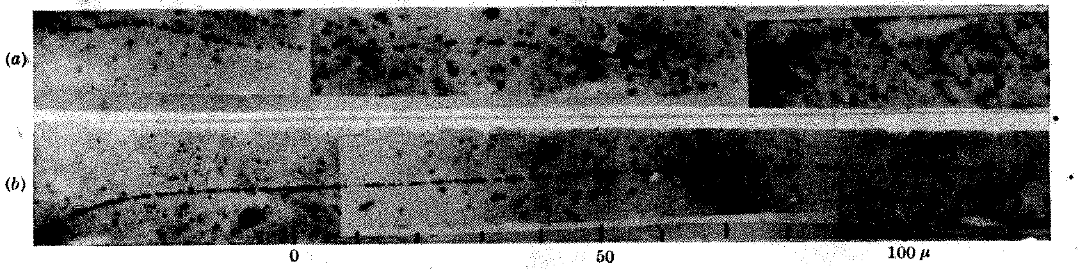

Fig. 1. (*a*) TRACK OF A MESON OF MASS 250 ± 50 m_e COMING TO REST IN THE EMULSION. (*b*) TRACK OF A PROTON FOUND ON THE SAME PLATE

Unfortunately, this work was interrupted by the War and only resumed a few months ago.

We have recently been using the new Ilford *C*2 emulsions of thickness 40 μ. In some three square centimetres which have been examined, fifteen long tracks due probably to protons of energy 10–20 MeV., a track of length 180 μ which appears to be that of a slow meson coming to rest in the emulsion, together with a star of eleven charged particles have been found. Cloud chamber observations show that about one slow meson should be observed per eight slow protons[5], in agreement in order of magnitude with one per fifteen obtained with this plate.

A photograph of the meson track is shown in Fig. 1 *a*. It can be seen that the scattering along its length is appreciably greater than along an equal length of proton track shown in Fig. 1 *b*. This fact affords an approximate method of determining the mass of the meson[3]. The observed scattering is consistent with that of a particle having a mass of about 200 m_e, where m_e is the mass of an electron. A better value may be obtained from a second method which involves counting the number of developed grains per unit length of the track and comparing the results with similar measurements made along the proton track shown in Fig. 1 *b*, having a total length of 1040 μ in the emulsion. The number of grains *n* per 15 μ of track were counted, and a curve of *n* against range in the emulsion was plotted for each particle. The residual range of each particle was found from the curve for points having the same value of *n* (that is, when the two particles have the same velocity). This gives a value for the mass of the meson of 250 ± 50 m_e, but the actual value is inevitably subject to large statistical errors unless a large number of tracks are available for measurement. It is not possible to say whether or not the meson decayed with the emission of a β-particle, because an electron having energy equal to half the rest-mass energy of the meson (that is, ~ 50 MeV.) would leave no distinguishable track in the emulsion.

A single photograph of the star is shown in Fig. 2. The measured length of each track is given using the notation used by Powell and Occhialini[4], that is, (*e*) signifies that the particle stops in the emulsion, (*s*) that it leaves the surface, and (*g*) that it passes into the glass. *A*, *E*, *G* and *I* are probably due to protons of energy 10–20 MeV., while *C*, *F*, *H*, *J* and *K* may represent the tracks of α-particles of energy ~ 10 MeV. *B* appears to be the track of a particle which is just heavier than an α-particle; *D*, on the other hand, represents the track of a much heavier particle. Assuming that the star represents the disintegration of either a silver or bromine atom, these particles should be accompanied by about ten or twelve neutrons, and we estimate that the total energy given to the nucleus by the incoming particle is of the order of 400 MeV. The proton and neutron intensities at sea-level are very weak, while fast negatively charged mesons make up about 35 per cent of the total radiation. Thus, this star may be another example of meson capture by a nucleus.

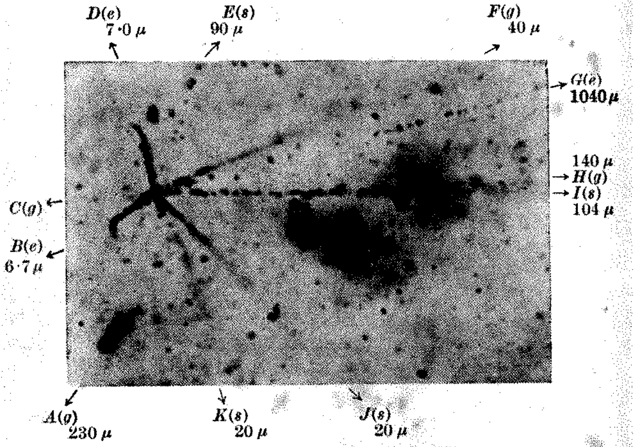

Fig. 2. A COSMIC RAY STAR FOUND IN ILFORD *C*2 EMULSION EXPOSED AT SEA-LEVEL

In conclusion, we wish to express our gratitude to Prof. R. M. Davies for many helpful discussions, to the heads of the Departments of Botany and Zoology for the loan of microscopes, and to Dr. C. F. Powell of the University of Bristol for bringing to our notice the new Ilford emulsions.

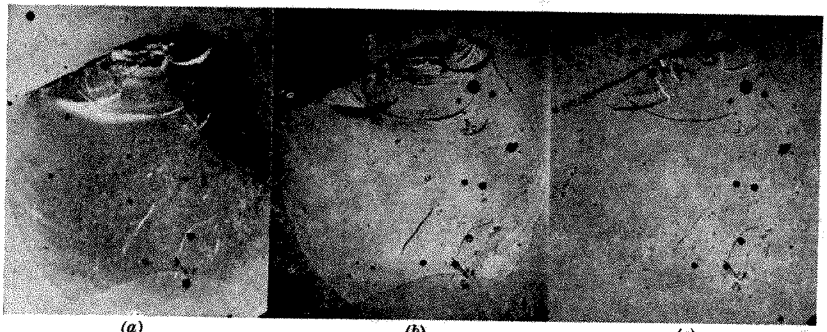
A Variable Phase-Contrast System for Microscopy

PHASE-CONTRAST effects occur when the paths of the dioptric and diffracted rays between object and image differ sufficiently to produce some degree of interference. Were it possible to polarize the diffracted rays and dioptric rays at right angles to one another, a path difference could be introduced by passing them through a birefringent screen, the refractive index of which, being different for two perpendicularly polarized rays, would produce the



(a) (b) (c)

GLASS FRAGMENT IN GLYCOL PHTHALATE, MAGNIFICATION 25. (a) BRIGHT FIELD EFFECT WITH PHASE CONTRAST. (b) DARK FIELD EFFECT WITH PHASE CONTRAST. (c) APPEARANCE WITHOUT PHASE CONTRAST

effect of different optical thicknesses accordingly. Such a screen might be a mica plate causing a fixed difference of a quarter of a wave-length, or a compensator of the Babinet–Soleil type producing a variable difference.

Experiments have been carried out to test the possibilities of a variable phase-contrast system based on this principle. To reduce constructional difficulty in the initial stages, a simple arrangement was used, axial plane polarized light being employed with a 1-in. objective, at the back focus of which was mounted a mica retardation screen. This consisted of a quarter-wave plate having its central portion cut out, rotated 90°, and cemented back again. Consequently, the 'fast' direction of the centre and the 'slow' one of the rim were aligned, and while the dioptric rays from the specimen were focused in the central portion, the diffracted rays passed through the periphery. Thus the dioptric rays could be advanced by a quarter wave-length with respect to the diffracted rays, or, by turning the disk 90°, retarded by the same amount.

The accompanying photographs were taken through a retardation screen of 'Cellophane' built up in a similar way, but with an angle of about 45° between the 'fast' axes of the central part and the rim. By adjustment of the analyser, the dioptric ray can be weakened as desired, and by rotation of the disk relative to the polarization plane the appearance can be varied in the manner shown. The object, a fragment of glass ($n = 1 \cdot 54$) mounted in glycol phthalate ($n = 1 \cdot 53$), was chosen for its intractable nature, and the absence of double refraction checked.

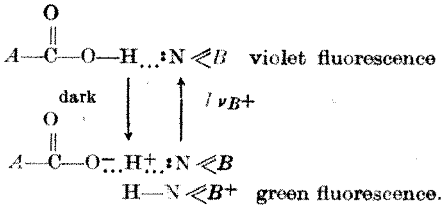
Proton Transfer between Organic Molecules Caused by Light

PROTON exchanges between acidic and basic organic compounds in solutions take place spontaneously according to the relative proton 'affinities' of the partners. The possibility of a proton transfer against the thermodynamic potential under the action of light seems not to have been demonstrated by a clear-cut experiment. In an investigation of photochemical reactions of organic compounds at low temperatures, we were able to show such an effect.

For the observation of a proton transfer without the intervention of a solvent, both components were sublimed *in vacuo* on to a cooled surface as a thin film in which a perfect mixture of the acidic and basic molecules was thus achieved. The experimental arrangement used was similar to that previously described[1]. As proton donors we chose easily sublimable crystalline organic acids, such as oxalic, benzoic, salicylic, succinic, terephthalic acids. As proton acceptor we used acridine, the well-known fluorescent indicator of pH in aqueous solutions, because the violet fluorescence of its neutral molecule is transformed into a bright green fluorescence in an acidified solution when this molecule incorporates a proton, being transformed into the acridinic cation with a corresponding change in the absorption and fluorescence spectra. This sharp change in the colour of the fluorescence was used here to detect the detachment of the proton from the acridinic cation under the action of light.

When both components condense from the vapour phase on to the surface kept at – 180° C., the close association of the acid with acridine will clearly lead to the formation of hydrogen bonds between the partners, as shown in the upper line of the diagram below, where the acid is designated by A, the basic molecule of acridine by B, their main groups being explicitly shown. At – 180° the violet fluorescence of the neutral acridine molecule rapidly changes, on standing, to a green fluorescence, this process being extremely rapid at room temperature. As can be judged from the position of the maximum in the fluorescence spectrum, this green fluorescence belongs to the acridinic cation, formed here at the cost of the proton detached from the acid (see lower part of the diagram). This process does not need any activation by light and occurs in a purely thermal way, equally well in the dark, as shown by the arrow pointing downwards. In all cases the fluorescence was excited by filtered ultra-violet radiation of the mercury lines at 366 mμ.



A—C(=O)—O—H...:N⋞B violet fluorescence
dark
hν_{B+}
A—C(=O)—O⁻...H⁺...:N⋞B
H—N⋞B⁺ green fluorescence.

Now, when the sublimated, composite, green fluorescing film is exposed for a short time to ultra-violet light of shorter wave-length in the range of the second maximum in the absorption spectrum of the acridinic cation (about 250 mμ), the fluorescence of the exposed area assumes a violet colour with a spectrum characteristic of the acridine molecule (arrow pointing upwards). But if the short ultraviolet stimulation is cut off, this violet fluorescence gradually disappears, being replaced by the initial green one. The process can be repeated at – 180° many times without any indication of an irreversible change. We infer from this experiment that absorption of light by the acridinic cation has activated the N—H bond and effected the detachment of the proton with its simultaneous transfer to the acid anion in a kind of coupled predissociation (see diagram). An energetic coupling between the partners must necessarily be assumed, since for succinic and terephthalic acids even relatively long wave-lengths in the first absorption maximum (at 360 mμ) of the acridinic cation are photo-active for this process. This reversible photo-reaction cannot be duplicated by the application of heat.

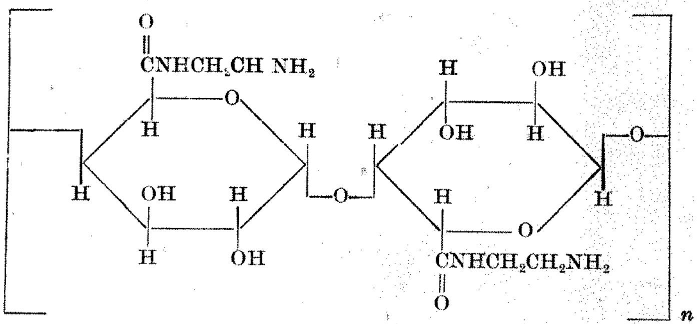
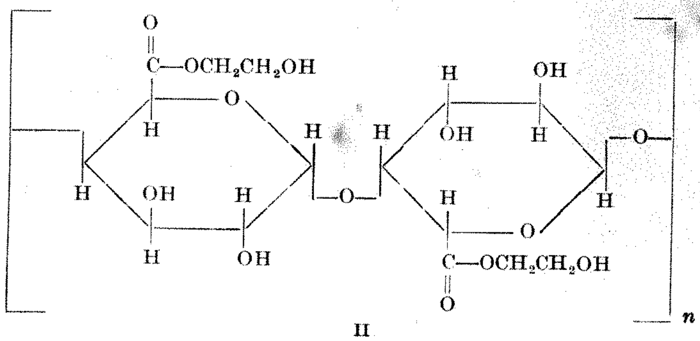
Derivatives of Pectic Acid as Models of Proteins

THE constitution and properties of pectic substances have been intensively studied[1]. Pectins, when reacting with the bifunctional formaldehyde under acidic conditions, have been found to form three-dimensional networks. This process takes place much more slowly than the corresponding reaction with polysaccharides containing primary hydroxyl groups (for example, lichenin). An accelerated reaction of pectic substances with formaldehyde may be obtained by using the mono-glycol ester of pectic acid (I) instead of the natural methyl ester. The glycol ester is easily produced[2] by treating pectic acid with ethylene oxide. A greater reactivity with formaldehyde, even under neutral conditions, would be expected upon the introduction of primary amino-groups into the pectic acid molecule.



I

Carson[3] described a simple method for the preparation of n-alkyl-amides of pectic acid by the reaction of their methyl esters with primary aliphatic amines. We have studied similar reactions with aliphatic diamines. Thus an amide of the following structure (II) was prepared by the action of ethylenediamine on the glycol ester of pectic acid (totally esterified):



II

A complete conversion of ester to amide groups produces bases of high molecular weight, every link of the chain molecule carrying a branch with a primary amino-group at its end. The aqueous solution of this macromolecular substance is found to produce a gel easily when formaldehyde is added. These bases form insoluble salts with high molecular weight acids. Similar to the polyethylenimines[4], these ethylenediamine derivatives of pectic acid precipitate pectic acid itself.

If the conversion of ester to amide groups is incomplete, or if the amides formed undergo a partial hydrolysis, derivatives of pectic acid with a structure similar to that described above but containing a certain percentage of free carboxyl groups are obtained. In this case every chain molecule carries acidic carboxyl as well as basic amino-groups. These macromolecules possess a dipolar ionic structure, and in many respects show properties similar to those of proteins; for example, coagulation or minimum viscosity at the isoelectric point. Water-insoluble substances of this type can be rendered soluble by the addition of acid, alkali or even neutral salts. In order to characterize these ampholytes, the methods of protein chemistry have proved to be suitable (Van Slyke method, Sørensen titration, etc.).

Ampholytes with any desired proportion of carboxyl- to amino-groups, as well as ampholytes of different size, can be produced from esters of polyuronic acids. It should be possible to relate their properties (solubility, viscosity, electrochemical and optical behaviour, etc.) to the fairly well-established structure of these macromolecules, whereas with proteins such a correlation encounters, for the time being, much greater difficulties.

Further investigations are in progress.

Detection of End Groups in Polymer Molecules

THE radical theory of vinyl polymerization is confirmed by the identification of so-called catalyst fragments in the polymer molecule. The usual method is to purify the polymer by repeated re-precipitation and to use a catalyst containing an easily identifiable element. Thus when tribromobenzoyl peroxide has been used as the catalyst and the molecular weight of the product is not too high, it is possible to identify bromine in the polymer after repeated purification[1].

A method has now been found by which the presence of an end group in styrene polymerized with sodium sulphite[2] is readily demonstrated irrespective of the molecular weight and without any special purification of the polymer. The radical in this case is monothionic acid, so that every polymer molecule is equivalent to an acid of very high molecular weight. When 1,000 ml. of a 0·2 per cent solution of such polymer in benzene is mixed in a gently rotating bottle with 10 gm. of solid caustic potash pellets, the viscosity of the solution gradually increases to a maximum of approximately twice its initial value over a period of perhaps 50 hours. With a 0·4 per cent solution the viscosity increases several times, while with a 0·05 per cent solution the viscosity is scarcely changed. By the addition of a standardized solution of hydrochloric acid gas in benzene, it is possible to titrate the potassium salt of the polymer by continuous determination of the viscosity. With the first small addition the viscosity remains unchanged, and with further addition it falls rapidly to a constant value which is unchanged even after the addition of a considerable excess of acid. The initial flat portion is thought to be due to traces of salts of acids of low dissociation constant which must first be neutralized before the salt of the polymer is attacked. The calculation of the number average molecular weight from end-group titration in this way, therefore, necessitates some knowledge of the dissociation constant. Assuming that the dissociation constant of polystyrene acid is equal to that of hydrochloric acid under the same conditions, then a polystyrene sample having a specific viscosity of 0·66 at a concentration of 0·1 per cent in benzene gave an equivalent weight of 32,000 by viscometric titration. For an exact interpretation the effect of surface adsorption in such dilute solutions would need consideration.

The alkali-treated polymer solution gives a specific viscosity/concentration curve which cannot be extrapolated to zero concentration with any certainty, whereas the polymer acid under the same conditions is more nearly linear, which gives further light on the Staudinger molecular weight rule.

Misuse of 'Deduced Ratios' in the Estimation of Median Effective Doses

Dragstedt and Lang[1] wrote: "It seems to us obvious that a rabbit that died from 100 mgm. would have died of any higher dose and one that survived from 150 mgm. per kilogram would have survived from any lesser dose", and tabulated their "mortality percentages" as deduced according to "this rationale" from experienced ratios at the various doses. Behrens[2], with a similar idea, pointed out its limitations: "Unter der Voraussetzung, dass es sich um ein stetiges Kollektiv handelt, dass in den einzelnen Gruppen gleichviel Tiere angesetzt werden [or percentages in place of experienced effect ratios be used] und dass die Gruppenabstände nach beiden Seiten [of the expected median dose] gleichgross sind (arithmetische Reihe [elsewhere he correctly advocates a geometric progression]), ist zu erwarten, dass die Gesamptzahl der bei niederen Dosen Gestorbenen gleich ist derjenigen der Überlebenden bei höheren Dosen vom erwarteten Wert aus betrachtet. Selbstverständlich müssen wir die gesamte Ausdehnung unseres Kollektives mit den Gruppen erfassen." Behrens pointed out that the deduced ratio at a given dose is not the mortality ratio except at the value 1/2; that the ratios deal with areas on, rather than with ordinates of, the cumulative frequency curve.

Burn[3] briefly outlined the procedure and gave an example from Behrens, but did not mention the requirements for legitimate use, and, like Dragstedt and Lang, spoke of the deduced ratios as (deduced) mortality ordinates. Following such easy examples, many workers (including myself, though I was fortunate enough to discover the error before publication), have treated the ratios as mortalities at a given dose, with asymmetrical and/or non-geometric dosage schedule, unequal numbers of animals at dose-levels, and/or incomplete coverage of the mortality range (from high probability of no effects at one end to that of 100 per cent effects at the other). The consequences, apparent with some experimentation on log dose-probit charts, are more or less bias in the estimated median dose, and, in calling the ratios ordinates of the cumulative frequency curve, distortion from normality and reduction of *apparent* inter-animal dispersion. The bottom of the pitfall is thus attained when one attempts to estimate, in terms of the deduced ratios, the standard error of the so-deduced median dose[4]. The error is underestimated.

The *Plesianthropus* Skull

DR. R. BROOM's account[1] of the new *Plesianthropus* skull makes it possible to take another step towards assigning to this form the place it occupies in the Primate series. His Fig. 2 shows clearly that the lacrimal and the ethmoid articulate over a wide area in the orbit. Possibly, the sphenoid and ethmoid articulate superficially in the anterior fossa (Fig. 1), although it is very difficult to accept Broom's hypothetical median part of the suture line as being correctly placed. In both cases the likeness with the Asiatic rather than with the African anthropoids is noted by Broom; but he makes no mention of the condition of the typically simian maxillary–premaxillary suture present on the face. The features that Broom has already described appear to verify the dictum of Klaatsch that "the less an ape has changed from its original form just so much the more human it appears", and perhaps agreement could be reached by assuming that *Plesianthropus* is a primitive and generalized anthropoid ape that has not attained to all the specializations characteristic of the modern apes, and is therefore nearer to the basal stock of the Primates from which man arose.

ACQUIRED RESISTANCE TO PALUDRINE IN *PLASMODIUM GALLINACEUM*

Acquired Resistance and Persistence after Passage through the Mosquito

ACQUIRED drug-resistance is well known in trypanosomes and bacteria; but hitherto there have been only four accounts of this phenomenon in experimental work upon malaria. The Sergents[1,2], and Kritschewski and Rubinstein[3], claim to have induced resistance to quinine in *Plasmodium relictum*, though the Sergents' claim is based on one case only. Kritschewski and Halperin[4] state that the quinine-resistance sometimes, though not invariably, persisted after cyclical passage through *Culex pipiens*. Acquired resistance to plasmoquine and quinine was described by Nauck[5], and to plasmochin by Fulton and Yorke[6] in blood-inoculated strains of *P. knowlesi*.

Paludrine (No. 4888, N^{1}-*p*-chlorophenyl-N^{5}-*iso*propylbiguanide), which was recently developed by Imperial Chemical (Pharmaceuticals), Ltd., is very active against avian[7] and against human malaria parasites[8,9], and promises to be a valuable drug in the treatment of malaria of man[10].

We have produced a forty-fold increase in resistance to paludrine in a strain of *Plasmodium gallinaceum* in chicks. In August 1946 we began to treat a normal strain of *P. gallinaceum*, passaged intravenously through chicks every second or third day, with the largest dose of paludrine hydrochloride (0·025 mgm.), which was without effect upon the parasites when given over a long period. Throughout this paper the doses are expressed in milligrams per 20 gm. of body weight of bird. After such treatment for a month, it was found that the parasites would tolerate a daily dose of 0·05 mgm. Thereafter the dose was gradually increased, as resistance to the drug developed, until after four and a half months parasites normal in appearance were developing in chicks receiving two doses daily each of 1·0 mgm., which is the largest dose that the host will tolerate.

The intensity of infections produced by standard inocula (50,000,000 parasites per chick) of the paludrine-resistant strain, in chicks receiving doses of paludrine ranging from 0·1 to 1·0 mgm. twice daily for three and a half days, was compared with similarly treated infections of the normal strain. Heavy infections were produced by the paludrine-resistant strain, whereas the development of the normal strain was inhibited completely.

The paludrine-resistant strain was tested for resistance to mepacrine hydrochloride and 4430 (N^{1}-*p*-chlorophenyl-N^{5}-methyl-N^{5}-*iso*propylbiguanide) acetate. In the minimum doses effective against the normal strain, the paludrine-resistant strain was not resistant to mepacrine, but showed definite resistance to 4430 (Table 1). Thus the resistance to paludrine is not specific but extends to the methyl homologue of the compound.

Attempts, extending over six months, to induce resistance to mepacrine in a normal strain of *P. gallinaceum* by the method used to produce paludrine-resistance failed; but after eight months treatment with pamaquin (= plasmochin) a normal strain of *P. gallinaceum* became resistant to the minimum effective dose (0·08 mgm.) of that drug.

TABLE 1. COMPARISON OF INTENSITY OF INFECTION OF PALU
RESISTANT AND NORMAL STRAINS

Normal strain	Paludrine-resistant strain	Normal strain	Paludri resistant s
Untreated birds		Mepacrine, 0·64 mgm.	
1076, (3)	1030 (2)	11 (5)	3 (
Untreated birds		No. 4430, 0·4 mgm.	
800 (2)	843 (2)	0 (4)	640 (4

The intensity of infection is expressed as the average numl parasites per 500 erythrocytes in groups of 2–5 birds. The n of birds in each experiment is given in brackets.

Exo-erythrocytic parasites similar in appear to those produced in normal infections were for by the paludrine-resistant strain.

Fairley and his co-workers[10] have shown that development of *P. falciparum* and *P. vivax* is inhibi in the mosquito if paludrine, even in small quantit is present in the infected blood. Such inhibition d [redacted] not occur in the paludrine-resistant strain of *gallinaceum*. Thus four batches of *Aëdes œgy* were allowed to gorge upon chicks infected with t [redacted] strain of *P. gallinaceum* resistant to twice-daily do of 0·4 mgm. of paludrine. Although the chicks we undergoing treatment with paludrine and had receiv a dose of drug four hours previous to being bitte oocysts were numerous on the gut wall of the mo quitoes on the fourth day, and the salivary glan became heavily infected with sporozoites. The proved to be infective to chicks. The parasites whi developed in the sporozoite-inoculated birds re tained the resistance to paludrine (Table 2). Th stability of the paludrine-resistance was further teste after three and five mosquito passages withou intervening drug treatment. These passages covere a period of three months, and the results showed tha there was no loss in paludrine-resistance (Table 2).

TABLE 2. COMPARISON OF INTENSITY OF INFECTION OF PALUDRINE RESISTANT AND NORMAL STRAINS

	Untreated birds		Drugged birds	
Dose twice daily	Normal strain	Paludrine-resistant strain	Normal strain	Paludrine-resistant strain
	After 1 mosquito passage			
Paludrine				
0·4	1076 (3)	979 (2)	1 (5)	540 (5)
0·4	1001 (6)	903 (6)	0 (6)	466 (6)
0·4	1075 (3)	617 (3)	1 (6)	158 (5)
0·4	559 (4)	544 (5)	0 (4)	398 (5)

* Minimum dose effective on normal strain.
The intensity of infection is expressed as the average number of parasites per 500 erythrocytes in groups of 2–6 birds. The number of birds in each experiment is given in brackets.

Apart from Kritschewski and Halperin's observations, experiments upon acquired drug resistance have hitherto been made upon organisms in which a sexual cycle of development is not known. The persistence of paludrine-resistance in *P. gallinaceum* after transmission by the mosquito is therefore of particular interest, as a definite sexual cycle of development is involved. Whatever may be the mechanism which produces this resistance, whether it be the selection of favourable mutants or the gradual adaptation of the parasites to the drug, resistance so produced is maintained through at least five sexual cycles, and also persists after a long sojourn in an environment (the mosquitoes' tissues) entirely different from that in which it was evolved.

A detailed account of these results will be published later. We are indebted to Imperial Chemical (Pharmaceuticals), Ltd.; for the gift of the paludrine, 4430, pamaquin and mepacrine. The work has been financed by the Medical Research Council.

Effects of Paludrine and Other Antimalarials

THE facility with which pathogenic protozoa and bacteria may acquire resistance to therapeutic agents, as a result of non-curative treatment of infections by these pathogens, is of profound significance both for the theory and for the practice of chemotherapy. The readiness with which trypanosome species may thus develop resistance to certain types of compound is well known; but malaria parasites in general have hitherto appeared singularly incapable of developing an acquired resistance, although a number of claims to have demonstrated this property have been made. Only one of these claims, that of Fulton and Yorke[1], referred to again below, can be incontrovertibly accepted.

Lourie[2] treated infections of *P. cathemerium*, in serial passage through canaries, with an intraperitoneal injection of 1 mgm. quinine hydrochloride every day for seventeen months, without producing quinine-resistance; similar treatment with 0·01 mgm. pamaquin (plasmochin) every day for nine and a half months failed to give rise to pamaquin-resistance. Fulton[3], working with *P. gallinaceum* in chickens, also failed to produce pamaquin-resistance by means of intermittent short courses of intensive treatment over a period of fifteen and a half months, and he suggested that the explanation may lie in the fact that the exo-erythrocytic forms, discovered by James and Tate[4], do not respond to treatment and therefore remain as a source of further pamaquin-sensitive erythrocytic forms. Fulton and Yorke[1] were able to produce pamaquin-resistance in *P. knowlesi* (in which exo-erythrocytic stages have not yet been demonstrated) in monkeys.

We have failed to produce resistance to quinine hydrochloride, mepacrine methanesulphonate, sulphadiazine, or 3349 (a forerunner of paludrine, see Curd, Davey and Rose[5]) in *P. gallinaceum*, in the course of intensive treatment of serially infected chicks, for periods extending over more than two years, as shown in the accompanying table (series 1 to 4). At the end of these periods the drug-treated strains proved to be as sensitive to the respective compounds as they were at the start.

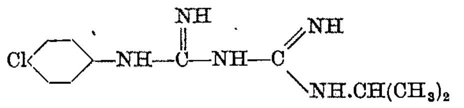
In the case of paludrine, however, a high degree of resistance appeared within about three months, in serially subinoculated and treated infections, in each of two experiments (series 5 and 6). In series 5 the infections were treated with doses of the order of the minimum effective for the normal strain, and in series 6 with doses in the region of the maximum tolerated by young chicks. The first indication of resistance in series 5 appeared two and a half months from the start (after a total of 54 doses of 0·25 mgm. per 50 gm. body-weight), and a month later, that is, at the end of the three and a half month period quoted in the table, infections were completely resistant to a course of seven doses of 0·25 mgm. in three and a half days. In series 6 a high degree of resistance—at least a tenfold increase—appeared suddenly at the end of the three-month period quoted in the table, a period which includes one month during which no treatment was administered. Both strains were then subjected to more treatment, in further serially inoculated chicks (a further aggregate of 3·5 mgm. in eleven days for series 5, and 70 mgm. in one month for series 6). Infections with parasites of each of these strains were then compared with parent strain infections, in respect of the 'minimum effective dose', as defined and as determined by the technique of Davey[6]. By this measure, the parasites of series 5 appeared to be about twenty times, and those of series 6 at least twenty to forty times, as resistant to paludrine as parasites of the parent strain.

HISTORY OF DRUG TREATMENTS IN SIX SERIES OF *P. gallinaceum* INFECTIONS

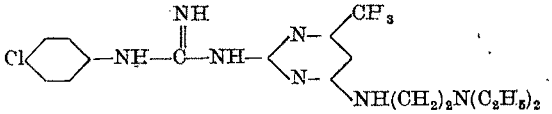
Series	Treated with	Duration of treatment		Dosage (by stomach tube)			Result
		Total (months)	No. of successive passages	Size of each dose (mgm. per 50 gm.)	Total no. of doses	Aggregate dosage for series (mgm. per 50 gm.)	
1	Quinine	29	73	7·5	516	3,870	No acquired resistance
2	Mepacrine	27	69	10·0	438	4,380	
3	Sulphadiazine	27	44	25·0	500	12,500	
4	3349	28	73	10·0	483	4,830	
5	Paludrine	3½	16	0·25	75	19	High degree of acquired resistance
6	,,	3	11	5·0 (occasionally 2·5 or 0·25)	32	119	

The paludrine-resistant strain of series 6 was found to be normally sensitive to quinine, mepacrine, sulphadiazine, and 3349. The absence of acquired resistance to 3349, on the part of the paludrine-resistant strain, coupled with the failure to produce resistance by prolonged exposure to 3349, is of special interest in view of the similarity between paludrine and 3349 in respect of prototropic possibilities, stressed by Curd, Davey and Rose[7] as associated with antimalarial activity in compounds of this general type.

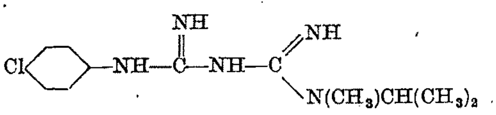
The paludrine-resistant strain was found to be fully resistant also to 4430[7], a close analogue of paludrine, and both these compounds lack the pyrimidine ring of the earlier prototypes of Curd, Davey and Rose which included 3349. This suggests that it may be the pyrimidine ring which determines the widely divergent behaviour of 3349 and paludrine in respect of acquired drug resistance, an interpretation which is further supported by the fact that the paludrine-resistant strain has been found to be normally sensitive also to 3502[5], a pyrimidine analogue of 3349.



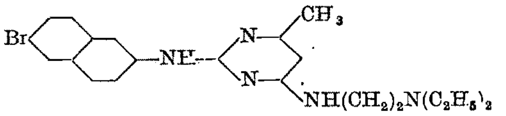
Paludrine



3349



4430



3502

About a month after the last dose of paludrine to the resistant strain of series 6, chicks infected with the strain were fed to *Aëdes ægypti*, which became heavily infected. There was clearly no impairment of transmissibility of this strain through mosquitoes, and when tested after mosquito-passage the strain was found to be as resistant to paludrine as before.

We are obliged to Dr. J. D. Fulton and Dr. J. W. S. Macfie for their co-operation in the early stages of this work, which was aided by a grant from the Medical Research Council. We are also grateful to Imperial Chemical Industries, Ltd., for supplying some of the compounds used. Full details will be published in the *Annals of Tropical Medicine and Parasitology*.

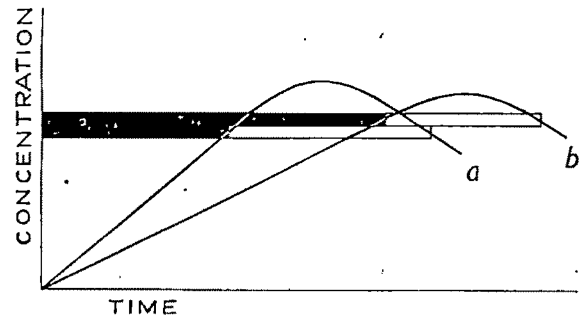
PHYSIOLOGY OF PATTERN FORMATION IN MALE AND FEMALE FEATHERS OF BARRED PLYMOUTH ROCK FOWLS

By G. MONTALENTI
Department of Genetics, University of Naples

ONLY very recently was I able to read Nickerson's paper[1] on barred pattern formation in chicken feathers. Nickerson's experimental analysis by means of melanophore transplantation according to H. B. Willier's technique, with other experiments and observations, demonstrates that the barring rhythm is determined by the melanophores themselves rather than by their reaction to some extrinsic rhythm or pre-existing pattern in the epidermal substratum of the feather germ (the latter view was maintained by Henke[2]). Thus barring is determined not only by the action of the genes independently in each follicle, as I supposed[3], but also by a rhythm inherent in the melanophores of each follicle. Furthermore, the suggestive hypothesis is put forward that "the barring rhythm is controlled by the action of melanophores through the medium of some diffusible substance which is capable of inhibiting the formation of pigment by melanophores present in the subjacent white regions of the developing feather germ"[1]. Such an interpretation fits well, as Nickerson points out, with the correlation that I have demonstrated between pattern characters and rate of growth of the feather, including the negative correlation between width of the white bar and growth-rate.

I should like now to direct attention to another point which has not been discussed by Nickerson, namely, the sexual dimorphism of pattern. The structural differences in feathers of certain tracts (for example, neck, saddle) between cock and hen are dependent on sex hormones[4] just as in many other breeds of fowl; but even in structurally identical feathers (for example, flights, breast feathers, etc.) a sexual dimorphism exists which has been analysed by Agostini[5]. The width of double bar (black plus white) is smaller in the male than in the female, both in juvenile and adult plumage (average ratio on breast feathers *c.* 0·78–1). The width of the black bar with respect to white is also smaller in the male feather: in the adult plumage (breast) of the cock the black bar comprises, on an average, 50 per cent of the double bar, while in the hen it comprises as much as 70 per cent. In other words, the male has a smaller double bar and a larger white bar than the female. These differences are statistically valid[5]. They do not depend on sex hormones, because castration, ovariectomy[5] and transplantation[3,6] do not alter them. Therefore, they are most probably directly determined by genetical constitution. Since barring is a sex-linked character and since the male is heterozygous in birds, one can suppose that such a phenotypic effect might be due to the presence of two doses of the *B* gene in the male and only one in the female[5]. How does this interpretation fit in with Nickerson's hypothesis?

Before testing this point, it must be emphasized that the different width of bars and different white/black ratios cannot be determined by different growth-rates in homologous feathers of male and female. I did not find any substantial difference in rate of



AVERAGE WIDTH OF THE BLACK AND WHITE BARS IN THE FEMALE (*above*) AND MALE (*below*) ANTERIOR BREAST FEATHERS OF BARRED PLYMOUTH ROCKS. HYPOTHETICAL CURVES OF THE CONCENTRATION OF THE PIGMENT-INHIBITING SUBSTANCE IN THE MALE (*a*) AND FEMALE (*b*) FEATHER GERMS AND THEIR THRESHOLD VALUES ARE ADJUSTED TO FIT THE ACTUAL WIDTH OF BARS

growth between homologous flights of a cock and a hen with very marked sexual dimorphism of the pattern[3]. Fluctuations in growth-rates of feathers of the same tract certainly do occur in different individuals, and possibly a small consistent sexual difference also exists. Unfortunately, I have not been able, for a long time, to work with chickens and therefore I have not been able to collect sufficient data relating to this point. In any event, from published and some unpublished data I also find that the differences in growth-rate between male and female breast feathers are not sufficiently high to account for the differences of pattern. In fact, one can calculate, starting from the male pattern, the growth-rate expected in order to account for the width of the female double bar. Pooling together the figures for three cocks and two hens, the average growth-rate of the hen's anterior breast feather should be, in order to agree with the width of pattern, 2·022 ± 0·0265 mm. per day, while it is actually 1·865 ± 0·0243; in the hen's posterior breast feather it should be 2·340 ± 0·0258, while it is in fact 2·160 ± 0·0381. The differences between the expected and observed figures are: 0·157 ± 0·0359 and 0·180 ± 0·0460, that is, they are significant. Therefore, I think that a difference in rate of growth, even if statistically ascertained, could not explain the different width of the double bar, to say nothing of the fact that the higher the rate of growth, the greater should be the proportion of white to black[3], which is just the contrary of what occurs.

The larger proportion of white in the male feather is easy to understand on the above assumption. As has often been pointed out, the genetical and physiological evidence is quite convincing that the *B* factor acts as a rhythmic suppressor of pigmentation: the positive effect, in barring, is inhibition of pigmentation, and Nickerson's hypothesis is in line with this view. Thus a higher dose of *B* gene (*BB* genotype in male) would presumably form a greater amount of the inhibiting substance, which would interrupt pigment formation for a longer time (about 1·3 to 1 is the male to female white bar ratio, absolute width, in the breast feather) than the *BO* female genotype.

It is more difficult to see why the width of the double bar should be larger in the hemizygous sex. Supposing that a threshold of a concentration of the inhibiting substance must be reached for the melanophores to react, and that the rate of formation of the substance is in some way proportional to the dose of *B* gene present; in the *BO* genotype the melanophores may work for a longer time (about 1·84 to 1 is the female to male black ratio, according to Agostini's average data) in forming pigment, before the inhibiting substance reaches the threshold concentration (hence the greater width of black bars). Once it is reached, the elimination of the substance should take place more rapidly (because of its lower total concentration), hence the absolute narrowness of the white bar. Since the black bar alone is, on the average, 1·84 times wider in male than in female breast feather, even a relatively short duration of the 'white' phase will bring about a greater width of the total bar in the female. The process might be represented in a diagrammatic way as in the accompanying illustration, where the relative width of black and white bars in male and female feathers are taken from the mean values of Agostini's data, while the curves of concentration of the inhibiting substance are, of course, entirely hypothetical and roughly adjusted to fit the actual morphological data.

BIOLOGICAL INVESTIGATIONS IN THE AEGEAN SEA

By PROF. ENRICO TORTONESE
Zoological Institute and Museum, University of Turin

As is well known, the eastern Mediterranean has been far less biologically explored than the western. It was therefore a very welcome occasion to spend several months (1943) in the Island of Rhodes (Aegean Sea) and carry out there a series of researches, the main result of which has been to add a number of species to those previously found and recorded. Knowledge of Aegean animals was first improved by E. Forbes about a century ago. In 1926 a group of Italian zoologists investigated the shores of Rhodes and neighbouring islands; other scattered data are to be found in various scientific papers, such as those concerning the famous *Thor* expedition. New and careful investigations are desirable for both an exact understanding of geographical distribution, variations and migrations of Mediterranean species and for ascertaining the spreading of those which have immigrated from the Red Sea through the Suez Canal: it is certain that some of them have reached the Aegean Sea, following the main current along the coasts of Syria and Asia Minor.

Of such zoological groups as Porifera, Cnidaria, Echinodermata, Nemertea, Tunicata and fishes no collections had hitherto been made in Rhodes and nothing is actually known. The marine fauna does not seem to be a very rich one; both species and individuals appear relatively scarce and it is improbable that this may be due to lack of proper researches. Steepness of submarine soil and frequent roughness of sea, consequent on almost continuous and violent winds, are probably responsible for this scantiness of life. General physiognomy, however typically Mediterranean, differs somewhat from that of the western shores of this Sea, as well as from that of its more northern parts; a number of species, for example, fishes, are peculiar to warm waters. Field work (hindered by war conditions) on various types of sea-bottom and sea-shore has revealed some noteworthy biocænosis. The predominance of *Cardita sulcata*, a lamellibranchiate molluscan, along the sandy beaches was already known; a peculiar association of *Asterina* and *Chiton* under the stones was now noted on rocky bottom in the harbour, with plenty of seaweeds; various other invertebrates were sharing the same habitat. Calcareous sponges, sea-anemones (*Anemonia sulcata*), two species of Nemerteans, free and sedentary Polychæta, Bryozoa (among them *Zoobotryon pellucidum*) and Ascidians were found in the harbour of Rhodes city and its neighbourhoods. *Actinia equina* seems to be missing, but on the opposite shores of Anatolia a good number of fine specimens were found. In shallow water during summer *Aplysia* was plentiful and grazing among seaweeds; a good series of other Mollusca were collected, too. Among other species were *Tethys leporina* and two different *Octopus*. Colonies of *Pyrosoma* and some Hydromedusæ were the only pelagic animals that could be obtained. Twenty species of Echinoderms were gathered: among them *Tethyaster*, *Ceramaster* and *Centrostephanus* were quite common in rather deep water, more or less distant from the shore. Crustaceans were fairly abundant, and among the largest Malacostraca *Squilla mantis*, *Scyllarides latus*, *Maia squinado*, *Calappa granulata* and *Dromia vulgaris* do not appear to have been previously noticed, as well as *Pagurus striatus*, a common dweller of large shells of *Cassis sulcosa* and *Murex trunculus*.

Fishes were particularly looked for, and collected species amounted to 116, of which six were Plagiostomia. Fishermen are few, and their work even in normal times is not a profitable one. The cause is to be found both in scarcity of plankton, that does not foster a rich fish-life, and in the nature of the sea-bottom, that forbids using some fishing technique otherwise advantageous. Ambiental conditions are unfavourable to fishes the life of which is largely dependent on development of continental shelf, as are Heterosomata, of which four species only were obtained. Shoals of migratory fishes (Scombroids, etc.) coming from the Black Sea or going there appear near Rhodes, but cannot support fisheries on an industrial scale. As a whole, these animals are much more numerous along the coasts of Asia Minor. Large sea-basses, mullets, red mullets, hakes and some sparoids were most frequently observed to be sold. This fish fauna shows a rather tropical character, that is stressed not only by such chiefly tropical families as Labroids and Carangoids or genera such as *Sardinella* and *Sparisoma*, but also by the presence of Red Sea immigrants. Only one of these, *Siganus rivulatus*, had previously been found in Aegean waters. Two other species may now be added—*Hemirhamphus marginatus* and *Monacanthus setifer*, the latter hitherto found only in Palestine. Apart from some species such as the small ray (*Raia radula*), that are more or less localized and the recognition of which is therefore interesting, four species, of which a single specimen was found in Rhodes, deserve particular mention. *Lobotes surinamensis*, a percoid, and *Remilegia australis*, a remora (sucking-fish), are tropical species of which we had but one Mediterranean record: the former was captured in Palermo (1875), the latter in Trieste (1881). *Scyris alexandrinus*, a form of deep-bodied carangoid, seems to be rare and until now was reported only from North Africa and Syria. *Gobius thori* is a little goby of which only the type specimen, collected by the *Thor* near Tenedo (northern Aegean Sea) many years ago, was known.

All this material was unfortunately lost, but all notes and drawings were fortunately preserved, so that it has been possible to deal with it particularly in separate papers, that will appear—it is hoped—as soon as printing difficulties will allow.

RADIOCHEMISTRY IN BRITAIN

OPENING OF THE LONDONDERRY LABORATORY AT DURHAM

GREAT BRITAIN was in the forefront of original research on the chemistry of the radio-elements so long as Frederick Soddy, after his return from Montreal, was devoting his activities to this field. Much of the experimental material which led to his conception of isotopy was collected in his laboratories in Glasgow by A. Fleck; the first thorium-lead was prepared there and its atomic weight determined; and protoactinium was discovered by Soddy and Cranston in Aberdeen simultaneously with Hahn and Meitner in Berlin-Dahlem. No chemical laboratory in Great Britain, however, has followed up the tradition, so that from about 1918 on, the centres of radiochemical research were the Laboratoire Curie in Paris, and the Radium Department of the Kaiser Wilhelm Institut für Chemie at Dahlem, under Otto Hahn. How important their work was may be seen from the one fact that the discovery of the fission of uranium was an achievement to which the systematic study of the chemical products of the uranium irradiation was bound to lead, and to which the Paris laboratory had already come very close when Hahn and Strassmann's fundamental paper appeared. In Britain no corresponding work was undertaken, in spite of several physicists being greatly interested in the problem.

The need for a revival of radiochemistry was keenly felt during the Second World War, when the military and economic possibilities of the use of atomic energy had been recognized, and in Montreal a joint British–Canadian Government team, first under the directorship of Dr. H. Halban, and later under that of Prof. J. D. Cockcroft, did research work on uranium fission. The chemistry division of that team, built up during the years 1943–45 under Prof. F. A. Paneth, comprised finally more than thirty graduates, many of whom had been recruited in Britain.

It would have been deplorable if at the end of the War still no British university had shown interest in the study of radiochemistry. Fortunately, the University of Durham, with the support of the University Grants Committee, found ways and means of building a laboratory in which radiochemical specialists can carry out their researches and, at the same time, train young chemists in the particular techniques which will enable them to collaborat with the departments of nuclear physics in univer ties and Government establishments, and also w biologists interested in the use of radioactive tracers. The laboratory, designed by Dr. E. Glueckauf and Mr. L. Gradon, consists of two modest one-story buildings near the main Science Laboratories, one equipped for the chemical treatment of radioactive substances of low activities, the other for those emitting strong radiations.

This Laboratory—named after Lord Londonderry, chancellor of the University of Durham, who has personally contributed to the cost of its erection by a generous gift—was formally opened on June 4 by Viscount Portal of Hungerford, on whom the honorary degree of D.C.L. was conferred on this occasion. The ceremony was attended by Sir Wallace Akers, who during the War was director of the United Kingdom Government's atomic energy project; Dr. A. Fleck, Soddy's old collaborator; Dr. J. D. Cockcroft, now in charge of the Atomic Energy Research Establishment at Harwell; Dr. J. Guéron, of the Commissariat de l'Energie Atomique in Paris; and many other well-known men of science. Lord Portal, who after his brilliant R.A.F. career is now directing the Government's efforts towards the peace-time utilization of atomic energy, replied with a speech which dealt largely with the relationship of British universities to the State. We print below some extracts from Lord Portal's address.

The practice of the universities of Great Britain in honouring members of the fighting services with degrees is, in my humble opinion, a very sound one, quite apart from the personal pleasure it gives to the recipients. It tends to emphasize one of the clearest lessons of the late War, that to secure the greatest possible efficiency the fighting services must call to their aid, in peace as well as in war, all the best talent in civil life, and make full use in many different ways of the type of brain-power that is to be found in the universities rather than in the fighting services in peace-time. The closer you can draw the bonds between the universities and the fighting services, the better for the country.

Much of the special scientific work done in the War by, or under the guidance of, members of the staff of the University of Durham was of great importance, directly or indirectly, to the fighting services. Under such distinguished men as Profs. Curtis, Riley and Wager, Drs. Valentine, Richardson and Varley, and Mr. Cragg, problems ranging from camouflage to the case-hardening of steel; from air photography to agricultural pests; from hydrodynamics to the dehydration of food, were tackled with great success.

But to-day we are thinking mainly of radiochemistry, because this new Laboratory will be the first school in that subject to be formed in Great Britain, and the subject is one of very great importance if the peaceful uses of atomic energy are to be fully developed. It is good news that the school is to be under the charge of so eminent a man as Prof. F. A. Paneth, whose reputation extends far beyond this country and whom we were all delighted to see honoured recently with the fellowship of the Royal Society. He and some of his associates from this University, Drs. Chackett and Musgrave, and Mr. Martin and Mr. Morgan, did valuable work in Canada during the War, and there is much for them to do here in the future. For without skilled radiochemists in adequate numbers, we shall not be able to develop fully the use of the radioactive isotopes which we hope will be of such enormous benefit to future research in medicine, agriculture and industry generally.

I hope you will not think it inappropriate if I conclude with one or two observations which are not strictly relevant to this occasion or to this University.

During the last year my work has brought me into close contact with many of the most eminent men of science in Great Britain. Perhaps it is a bit late for me to hope to make good the omissions of a classical education, but I can say with truth how enormously I respect these great men and the power and integrity of their brains, and how immensely helpful I have found their advice, even when I am unable to follow their calculations. In the course of my contact with them, and in reading what others have written, I have realized the depth of feeling which exists far and wide in the world of science about the responsibility of scientific men for the consequences of the discoveries they have made in the realm of nuclear fission.

Like the discovery of flying, this atom business is in many ways very awkward. I sympathize very much with the scientific men. It is perfectly true that the prospects for the good uses of atomic energy which are already foreseen, and for the discovery of others not yet foreseen, are at present gravely affected by international distrust and the resulting need for secrecy and strict Government control of the whole business. Secrecy is in itself a brake on progress, and if it has to be continued indefinitely it may well drive some good men in disgust to other lines of research where freedom is allowed and can do no harm. Government control, though it is absolutely necessary under present conditions, and perhaps always will be, means that the best brains in industry, particularly on the engineering and metallurgical sides which are every bit as important as the nuclear-physical side, are difficult to mobilize upon the problems of development.

No one could recognize all this more clearly than we officials who have to help to administer the law, but it really is no use pretending that conditions to-day are appropriate for the casting of all secrecy to the winds in the name of the freedom of science. What we can and will do is to try, consistently with our duty, to minimize the inconvenience caused by the restrictions and to interpret the will of Parliament in a liberal spirit.

I do not think that, on the long view, there need be any uneasiness about the British contribution to atomic energy, though the rate of progress is bound to be affected by the number of urgent things Britain has to tackle simultaneously at the present time. We may not have the volume of human and material resources that some other nations have, and the maintenance of a proper balance between research directed to the execution of a short-term programme and that required for the needs of long-term progress and training will always be a problem. But I do believe we have in Britain the quality of human genius which will before long put us in the very front rank. Quality is what we must bank on, and it is to the British universities that we must chiefly look to foster and maintain the quality of future generations of our scientists and engineers.

May I express the hope and belief of all who are here to-day that the Londonderry Laboratory will see long and useful service, and that the work done there will be outstanding in its contribution to the ultimate benefit of mankind.

FORTHCOMING EVENTS

Tuesday, July 1

Royal Society of Medicine (at 1 Wimpole Street, London, W.1), at 1.30 p.m.—Annual General Meeting.

Wednesday, July 2—Thursday, July 3

Irish Chemical Association (joint meeting with the Dublin Section of the Royal Institute of Chemistry, in the Department of Chemistry, University College, Upper Merrion Street, Dublin).—Colloquium on "The Industrial Utilization of Agricultural Products and of Seaweed".

Wednesday, July 2

At 10.30 a.m.—Prof. J. L. Simonsen, F.R.S.: "Agricultural Products and the Chemical Industry"; at 2.30 p.m.—Prof. J. B. Speakman: "The Production, Properties and Uses of Seaweed Rayon".

Thursday, July 3

At 10 a.m.—Prof. E. L. Hirst, F.R.S.: "The Utilization of Carbohydrate Products".

Friday, July 4

Geologists' Association (at the Geological Society of London, Burlington House, Piccadilly, London, W.1), at 6 p.m.—Dr. K. P. Oakley: "Geological Safari in East Africa".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Responsible Lecturer in Biology, and a Responsible Art Master, in the Municipal Technical College and School of Art—The Director of Education, Education Offices, Library Street, Blackburn (July 5).

Readership in Mining tenable at King's College, Newcastle-upon-Tyne—The Registrar, University Office, 45 North Bailey, Durham (July 5).

Head of the Department of Horticulture—The Principal, Yorkshire Institute of Agriculture, Askham Bryan, York (July 5).

Lecturer in Engineering Workshop Subjects, with special qualifications in Automobile Engineering—The Principal, Hendon Technical College, The Burroughs, Hendon, London, N.W.4 (July 5).

Senior Assistant in Mechanical Engineering—The Principal, Harris Institute, Corporation Street, Preston (July 5).

Head of the Building and Civil Engineering Department—The Principal, Royal Technical College, Peel Park, Salford 5 (July 5).

Lecturer in the Engineering Department of the County Technical College, Wednesbury—The Director of Education, County Education Offices, Stafford (July 5).

Organic Chemist at Long Ashton Research Station—The Secretary and Registrar, The University, Bristol 8 (July 7).

Lecturer in Mechanical Engineering—The Principal, Dudley and Staffordshire Technical College, Dudley (July 8).

Head of the Electrical Engineering Department of the Rutherford College of Technology—The Director of Education, Education Offices, Newcastle-upon-Tyne (July 8).

Lecturer in Chemistry, a Lecturer in Physics, and a Lecturer in Mechanical Engineering—The Principal, West Ham Municipal College, Romford Road, Stratford, London, E.15 (July 12).

Assistant Lecturers (2) in Physics—The Registrar, The University, Manchester 13 (July 12).

Professor of Physics at the Natal University College, Pietermaritzburg—The Secretary, Universities Bureau of the British Empire, 8 Park Street, London, W.1 (July 15).

Assistant Lecturer in Fuel Technology in the Department of Metallurgy—The Registrar, University College of South Wales, Cathays Park, Cardiff (July 15).

Chief Chemist (grade of Principal Scientific Officer or Senior Principal Scientific Officer), Scientific Officers or Senior Scientific Officers (Chemists and Physicists), and Technical Officers in the Testing and Dyeing and Finishing Departments—The Secretary, Wool Industries Research Association, Torridon, Leeds 8 (July 19).

Speech Therapist—The Clerk to the Governors, St. Bartholomew's Hospital, London, E.C.1 (July 19).

Chair of Physiology at Charing Cross Hospital Medical School—The Academic Registrar, University of London, Senate House, London, W.C.1 (July 21).

Assistant Professor of Applied Chemistry (Organic), an Assistant Professor of Applied Chemistry (Inorganic), and Lecturers (4) in Organic or Inorganic or Applied Chemistry or Biochemistry, at the Industrial Chemistry Institute, Alexandria—The Director, Egyptian Education Bureau, 4 Chesterfield Gardens, London, W.1 (July 31).

Professor of Theoretical Physics, an Assistant Professor of Physics, an Assistant Professor of Applied Mathematics, a Lecturer A of Applied Mathematics, and a Lecturer A of Experimental Physics, in the Faculty of Science, Farouk I University, Alexandria—The Director, Egyptian Education Bureau, 4 Chesterfield Gardens, London, W.1 (July 31).

Research Fellowship (Organic Chemist)—The Secretary, Institute of Child Health, Hospital for Sick Children, Great Ormond Street, London, W.C.1 (July 31).

Senior Lecturer in Mathematics in the University of Melbourne—The Secretary, Universities Bureau of the British Empire, 8 Park Street, London, W.1 (July 31).

Lecturer in Phonetics—The Secretary, The University, Edinburgh (July 31).

Lecturer in Chemistry in the University of Adelaide—The Secretary, Universities Bureau of the British Empire, 8 Park Street, London, W.1 (August 1).

Assistant Lecturer in the Department of Embryology—The Secretary, University College, Gower Street, London, W.C.1 (August 1).

Junior Lecturer in Physics in Canterbury University College, Christchurch, New Zealand—The Secretary, Universities Bureau of the British Empire, 8 Park Street, London, W.1 (August 8).

Lecturer in Anthropology in the University of Cambridge—Dr. G. E. Daniel, St. John's College, Cambridge (September 20).

Botanist to the Empire Potato Collection, Cambridge—The Secretary, Imperial Agricultural Bureaux, 2 Queen Anne's Gate Buildings, London, S.W.1 (September 30).

Director of the Parasitological Laboratory, Baghdad—The Crown Agents for the Colonies, 4 Millbank, London, S.W.1, quoting M.N.13725.

Head of the Mathematics Department—The Principal, Huddersfield Technical College, Huddersfield.

Lecturer in Physiology and Zoology—The Registrar, Technical College, Sunderland.

Lecturer in Chemistry (Grade I) in the School of Bakery—The Secretary, Royal Technical College, Glasgow.

Lecturer in Fuel Technology, and a Demonstrator (temporary) in the Department of Physics—The Registrar, King's College, Newcastle-upon-Tyne.

Lecturers in (*a*) Chemistry to B.Sc. standard, (*b*) Biology to Inter.B.Sc. standard, and (*c*) Mathematics, Pure and Applied, to B.Sc. standard—The Clerk, Northern Polytechnic, Holloway Road, London, N.7.

Lecturers (2) in Mathematics—The Principal and Clerk to the Governing Body, Wigan and District Mining and Technical College, Wigan.

Head of the Department of Chemistry—The Clerk, Northern Polytechnic, Holloway Road, London, N.7, endorsed 'H'.

Assistant Lecturer and Demonstrator in the Physics Department—The Secretary, King's College of Household and Social Science, Campden Hill Road, London, W.8.

Lecturer in Agricultural Chemistry (Animal Nutrition) in the Faculty of Agriculture and Horticulture—The Registrar, The University, Reading.

Lecturer, and Assistant Lecturers (2), in the Department of Biochemistry—The Secretary, University College, Gower Street, London, W.C.1.

Technician (Grade A), and Technicians (2, Grade B), with special knowledge of hæmatology—The Medical Superintendent, Dudley Road Hospital, Birmingham 18.
